Heap Roasting of Copper Ores.

Sulphide ores containing copper are roasted for the purpose of desulphurizing the ore as a preliminary to smelting. This is accomplished by roasting in reverberatory or mechanical rotary furnaces; in stalls or in heaps. The latter is the least expensive, as small plant or none at all is required, but it can only be practiced where no material damage will result to vegetation, as is usually the case in the arid regions of the southwest. Heap roasting is almost as old as the metallurgy of copper. It is accomplished by piling up heaps of the sulphide ores, usually containing a large percentage of iron and sulphur and a relatively small amount of copper, with generally some silica, aluminum, lime and magnesia in the gangue accompanying the ores. This ore is piled upon a layer of cord wood and the whole built up with care, and covered with the finer screenings to make the heap less impervious to draft. In selecting a site for roasting heaps consideration should be given the prevailing direction of the wind, that the fumes may not be constantly blown upon the office buildings, smelting works, etc., of the mine. Heap roasting should be conducted in the most economical manner possible, as a saving of 25 cents per ton of ore means a saving of about $1 on the matte, and much more on the ton of copper. Large heaps can be roasted at less cost per ton than small ones. A pile of ore 40 feet long, 24 feet wide and 6 feet high will contain about 240 tons of ore and should be roasted in this manner in about seventy days. To this should be added ten days for removing and rebuilding. The wood is first fired and this is communicated to the sulphur in the ore, which, taking fire, continues to burn, supplying its own fuel, until all has been consumed. Heaps are sometimes built side by side and the intervening space filled with ore, making one large heap.

Nevada's Eight-Hour Law.

At the last session of the Nevada Legislature a law was passed making eight hours a day's labor in mines. The law has been generally accepted by mine operators, but some difficulty has arisen between operators and miners over wages. At Dayton, in Lyon county, however, Mr. Phillips, operating a cyanide plant, refused to recognize the law, and worked his men longer than eight hours. He was fined $100 by a local justice, according to the provisions of the eight-hour law, and Mr. Phillips appealed to the District court, which court rendered a decision in favor of Phillips, declaring the eight-hour law to be unconstitutional. This has not tended to simplify matters in Nevada and further trouble is anticipated. Judge Murphy of the District court bases his decision on the State constitution, which provides that no law passed by the State Legislature covering two separate measures can become effective; that had the law been framed as in two separate laws, one affecting underground miners and the other applying to workers in metallurgical establishments, they would both have been constitutional, but as they are now, neither branch can be legally bound by the law. The intention is given no consideration. It is merely a technical point, however, which may be remedied at the next meeting of the Legislature in 1905.

Mine Taxation.

The Cœur d'Alenes, in Shoshone county, Idaho, are in danger of being sold out by the sheriff for nonpayment of taxes. For some time past the greater number of the companies owning and operating these mines have refused to pay the taxes assessed by the county. The county officials have placed an arbitrary valuation on the mines and plants. The companies have paid the taxes on the plants, but say the valuation on the mines is too high. It is expected that a long-fought legal battle will result. The entire trouble is the result of the law passed by the Idaho Legislature at its last session making patented mines pay taxes on an assessment based on the full market value of the property. The larger mines were assessed at $500,000 each. The taxes remaining unpaid, the county has advertised the several mines for sale for taxes in the usual manner.

The Deadly Fire Damp.

Another coal mine horror in Wyoming and the lives of over two hundred men reported sacrificed! This is fortunately not a daily occurrence, and yet it is so frequently similar accidents are chronicled that it seems that some of them at least might have been avoided had the necessary precautions been observed. The mine is at Hanna, on the line of the Union Pacific railroad. Two hundred and eighty-two men were on shift underground when the explosion of "fire damp" occurred, and of these two hundred and thirty-six are reported to be dead, only forty-six escaping, the others being killed outright by fire, concussion or caving roofs, or smothered by the "after damp." Rescuers attempted to relieve their entombed comrades but were unable to live in the dense gases which shut off the life-giving oxygen as completely as water could have done. Human life can endure but a few moments in such an atmosphere. The mine was recognized as dangerous by reason of the large amount of "fire damp" always present, but as the mine was supposed to be well ventilated no unusual danger was apprehended. The primary cause of the explosion is unknown, but it is presumed that one of the miners accidently or carelessly exposed an open light in the gas-laden atmosphere and the explosion followed.

Reasonably it is expected that miners for their own safety would look very carefully after the amount of fire damp present in mine workings and would see to it that a sufficient volume of fresh air was driven into the mine to secure safety, but long accustomed to the danger they became heedless by apparent immunity from harm. An important fact concerning fire damp, and one not generally known, even to many miners themselves, is that the danger from fire damp increases with a falling barometer. A mine where the percentage of fire damp is known, and it is not considered very dangerous, and where, in fact, the usual precautions render it comparatively safe, within twenty-four hours may become extremely dangerous by reason of a large increase in fire damp, due to lower barometer. It is not an uncommon thing for the atmospheric pressure to change by slow degrees and remain high or low for several days in succession, while a radical change may occurs within a few hours. A high barometer—equivalent to heavy atmospheric pressure—has a tendency to retard the flow of methane or "fire damp," and a low barometer, or light atmospheric pressure, seems to permit a more voluminous flow from the vein of coal or rocks inclosing it. Methane is the simplest compound of carbon and hydrogen known, and is the highest gas, next to hydrogen, known. It explodes with great violence when mixed with air when coming in contact with a flame or the electric spark, with the formation of water and carbon dioxide. The water vapor produced by an explosion of fire damp condenses with such rapidity, in fact, instantaneously, that it causes a second explosion, making two explosions following each other in rapid succession. In the event of a mine explosion such as that which has just occurred the men not killed by the explosion, by fire or caving ground, are promptly suffocated if an avenue of escape is not immediately open to them.

In view of the great danger in a gasy mine, and the known fact that the atmospheric pressure is an important factor, it seems that a recognition of this fact, and a consequent provision for sending a larger volume of air into the mine workings during the low barometer might possibly avert such calamities as that above mentioned.

THE silver market seems to have suffered less from the recent transfer of $1,423,000 in Mexican silver by the United States Government than might have been anticipated. This silver was deposited in the National Bank of Mexico, subject to the draft of the United States, in settlement of the Pious award. The silver is to be coined for use in the Philippines. The entire amount of this Mexican silver weighs about seventy tons.

Labor Unions.

The question of labor unions has entered the mining world the same as every place else, and it adds another factor to the problem of the investor as to how he shall get a return on his investment. The thing has been threshed over so much by writers and talkers that a few primary facts seem partially overlooked.

There is nothing new in the movement, though the method of operation is somewhat different from former procedure. Men who have little ambition, and who apparently expect to work for other people all their lives, have concluded that the old Bible story of labor being "a curse" is true, and, accordingly, that the less they work the less cursed they will be, and, meanwhile, the more they can get for what they do the better off everybody will be. The idea is based on a wrong understanding of the primal facts. The dignity of labor, the freedom of the individual man and the joy of useful, honorable, helpful existence is discarded for the dull combination of destroying force which cuts down all degrees of usefulness to the dead level of mediocrity and makes the least skillful man the standard for all the rest. True, the written code of many labor unions provide for high standards of skill in the craft, but it is equally true that the chief requirement is the payment of fixed dues, obedience to rules, and the total surrender and extinction of all individual rights. The chief, and, in cases the only object, seems to be to make demands upon the employer. If these demands are conceded then the union claims it to be a proof of the justice of its demands, regardless of the real facts or how the result was produced.

Usually the demand made is for increase of wages, or shorter hours, or a recognition of the union, the last being the most prolific cause of trouble. Success is more fatal than failure, as it fills the minds of the successful strikers with the idea that an incompetent man is worth as much and should get as high a wage as the competent man, with the result that the ordinary law of supply and demand is thrown over, and the rate of wages paid is not determined by the worth of the man receiving them, but by the demand of his union.

But it must constantly be borne in mind that the relations between the employer and the employe, so far as hours and wages are concerned, are governed by great natural laws over which neither employer nor employe have control—the law of the business world, which pays no heed to the wishes of wage giver or taker. Thus it is that, as regards wages, when times are good wages will advance regardless of the action of miners, and when times are bad no union can maintain a fixed wage scale. Wages advance or decline according to the eternal law of supply and demand, as is proved by the history of labor unions, which shows that in strikes for advance of wages 80% have been successful, while in strikes against the reduction of wages but 20% have been even temporarily successful.

That labor unions are beneficial is not to be denied; that they are susceptible of greater good is equally manifest, and one good way to advance their usefulness is that they be Americanized, that the members of any union recognize the difference between Old World and New World conditions and meet the progress and the spirit of the century by less of that old tyrannical flavor from across the sea, and more of the open, hearty co-operation that is a part of American commercial usage. Any worker in any capacity, whether employer or employe, is deserving of a fair division of the profits arising from the results of their joint labor, and members of labor unions can best secure their stated desire of advancement by ignoring those of their leaders who act in ignorance or defiance of business laws and requirements, and by exercising their own individual common sense and manhood.

PROBABLY as the outcome of the agitation last spring over the extensive timber land filings in Plumas, Lassen and Shasta counties, California, and the repeated charges of fraudulent entries, the Government has withdrawn from entry 272,000 acres in the Susanville, Cal., land office. This tract will be included in the Warner mountain forest reserve. A large portion of the land in that section is covered with fine timber.

CONCENTRATES.

THE man who is right and knows it never offers to compromise as long as he is determined to remain right.

MOST diamond drills are so constructed that they can bore at any desired angle, and the capacity ranges from 200 or 300 to 5000 feet or more, according to size of machine.

LARGE BODIES of soft ore are stoped in various regions, but only successfully underground by some system involving filling, to sustain the overhanging weight of roof—either ore or wall rock.

WHEN heated to about 600° C., aluminum becomes brittle and at a higher temperature becomes soft. Zinc acts in much the same way under similar treatment. Either may be pulverized in a mortar when thus heated.

THE fuel bill at a steam plant can be materially lessened by providing some sort of water heater if one is not already in place. The heater utilized the steam from the engine exhaust. There are several types of water heaters.

ROPE DRIVING is an economical and generally satisfactory method of transmitting power, and may be accomplished by use of either hemp, manila or steel ropes. The sheaves must be suited to the size and kind of rope for the best results.

THE duty per stamp in the mills on the Witwatersrand varies somewhat, but not so widely as in some other fields. The highest "capacity per stamp" reported is at the mill of the Lancaster West, where 5.93 tons are crushed daily per stamp.

EUCALYPTUS WOOD, a native of Australia, but now largely grown in California, is said to make excellent stamp stem guides. There are a great many varieties of this wood, but the red gum is said to be superior for the purpose indicated, requiring a minimum of lubrication.

IN stamp-mill construction care must be taken to prevent grease from getting into the mortars from cams, guides, or elsewhere. Care must also be taken to prevent sand from splashing up from the mortar into the guide blocks, as the grit will cause both stem and guide timbers to cut rapidly.

ORES containing nickel might be sent to the Camden, N. J., Reduction Works. The percentage of nickel which will pay to work, like any other metal, depends upon the conditions surrounding it and the situation. The ore is usually shipped in crude state or made into matte at the mine and this product shipped.

SHAFTS intended for the development and operation of coal mines should be sunk in the same manner as shafts intended for metal mines. If it is desirable to drill an oil well the best plan is to employ an experienced well driller and have the hole sunk by contract at a stated price per foot. Novices in well drilling often find their economy misplaced.

THE reason why some gold-bearing ores do not amalgamate readily is because the particles of gold are coated with a thin film of iron oxide, and consequently are not attacked by mercury. Grinding usually has the desired effect, brightening the gold when it is taken up readily by the quicksilver. This is one of the reasons why the arrastra is a superior device for amalgamating gold ores, particularly those occurring in the oxidized zone.

ALL veins and ore deposits are not associated with igneous rocks, but the greater number and most valuable are. It has also been noticed that where there was a belt of schist, slate or other rock in which gold-bearing veins occur, and where a portion of the veins thus occurring are associated with dikes and the remaining are not, those accompanied by dikes are usually more remunerative than those without them. This is a subject receiving much attention of late from mining geologists.

NO MILL MAN can afford to cling tenaciously to a "pet theory," for an attempt to apply this same theory to a new ore in another district may give unsatisfactory results. The most competent mill men are those who have a wide experience, treating many kinds of ore in many different districts. This sort of experience gives a man broader ideas and he soon is weaned away from his "pet theories," otherwise he must quit milling for some other occupation. Hard and fast rules will not always work in metallurgical processes.

REPLYING to the Dillon, Colo., query, the 125-volt, 12-ampere dynamo can be used to operate electro-magnets for the separation of magnetite from black sand. A single magnet may be built, or a group connected "in series," the size in either case may be such as to take only a part or the entire capacity of the dynamo. If the former, some other resistance must be added into the circuit to make up the difference (either use a series of lamps or a regular rheostat) The electro-magnets are made up of a cylindrical coil of wire wound around a soft-iron core (preferably a bundle of small straight rods rather than a solid core). The coil of wire is connected directly to the poles of the dynamo, except where other resistance is added, which may be on either side of the machine.

MALLEABLE CAST IRON is made of a special composition, cast and softened subsequently by annealing. The principal difference between malleable cast iron and other castings, such as car wheels, is due chiefly to the condition of carbon in each. The tensile strength of malleable castings should be from 42,000 to 48,000 pounds per square inch. It is not considered advisable to run them much over 50,000 pounds per square inch for the reason that the elasticity is reduced thereby, thus destroying one of the most valued properties of malleable casting.

THERE are many types of mortars. They differ chiefly in the width between the back and front discharge. A narrow mortar discharges more rapidly than a wide one; screens set inclining outward from base to top discharge more readily than vertical screens. Most modern mortars are fitted with liners, which, upon becoming worn, may be removed and replaced with new linings. This makes the life of a mortar almost indefinite. The modern mortar, like many other pieces of mining and milling machinery, has been evolved through years of experience and experiment.

GOLD may usually be bought in the Central and South American republics at considerably below its assay value. Most of the placer gold is worth from $17 to $19 per ounce and can usually be purchased at $11 to $12 per ounce in native silver money. As American exchange is only about 50 cents on the dollar, one can practically buy gold dust for about $5 an ounce, but the amount of gold thus obtainable is so small at any one place as to render it inadvisable to undertake any expense in the matter. The most of the gold offered for sale is bought up by the merchants and travelers who chance to learn of the whereabouts of the gold. In Colombia, S. A., platinum is also found with the gold—nuggets weighing as high as 14 ounces having been discovered recently. The value of native platinum varies greatly from $3 or $4 to about $20 per ounce, according to the purity of the grains.

CUPELS are usually made of pulverized bone ash, free from organic matter, ground and washed. Few assayers buy their cupels, preferring to make them. Cupels do not stand transportation nor rough handling well. They are made by moistening the bone ash with just sufficient warm water or stale beer, to cause a quantity of the ash to hold together when compressed in the hand. It should retain this shape when so compressed, but crumble readily when disturbed. Excellent cupels are also made from ground calcined magnesite (magnesium carbonate). The action of the cupel in absorbing lead oxide (litharge) is purely mechanical and not chemical. Experiment might prove that there are other absorbent substances which would make good cupels. While bone ash and calcined magnesite are both good absorbents of lead oxide the cupel must not be oompressed too tightly in the mold, or they will be too dense to work properly.

THE only material difference between a vein cropping which has a red color from one having a yellowish or brownish color is in the fact that the red is due to an anhydrous iron oxide and the yellow or brown color is due to a hydrous iron oxide. If the yellow or brown rock be burned, thereby driving out the water of crystallization, it will become red. The idea that red-colored vein croppings are uniformly of higher grade than those that are yellow or brown is not borne out by the facts. In both cases the color is due to oxidation of the normal ore, which on investigation will usually be found to have been iron sulphide. If the original sulphide was rich in precious metals the oxidized croppings are also likely to contain good values. There may also be gold present in quartz, independent of the iron oxides. The oxidized zones of the Homestake, South Dakota, are deep red; the veins of California are usually yellowish brown. In Arizona they are generally brown, but in some districts are red.

LARGE capacity in stamp batteries is not always synonymous with soft rock. A rock may be so soft as to completely "choke" up the screens, filling the battery and causing much trouble and delay. Some tuffs containing gold or silver act in this manner whenever an attempt is made to force large capacity upon the stamps. At Calico, Cal., some years since, a tufaceous ore could not be crushed faster than four tons per stamp per day, owing to the soft, spongy nature of the rock, but by an admixture of flinty rhyolite or brittle barite ore the capacity per stamp was increased to five and six tons per atamp daily. This was due to the fact that the hard, brittle particles of the rhyolite or barite, and sometimes jasper, cut the soft, pulpy tuff, driving it through the screen, keeping the latter clean. A hard granular ore will pulverize and pass through a screen of given mesh more quickly than hard, flinty ores which have a splintry fracture. Round-punched screens are suitable for the former and slotted screens for the latter rock.

VARIOUS METHODS of extinguishing mine fires are practiced. The most successful methods are tightly closing all openings leading into the mine shafts, tunnels, raises to the surface, etc.; flooding the mine with water; driving steam into the mine workings, and sending large volumes of carbon dioxide (carbonic acid gas) into the mine. The first remedy is a good one but is not always successful, owing to the fact that considerable oxygen reaches the fire through cracks and pores in the rock. The second method is direct and efficient, if the fire can be reached, but it often involves heavy loss from other causes than the damage by fire, disastrous caves often resulting; beside which, the expense of subsequently removing the water is always heavy and requires much time. The injection of steam into the workings is not efficient if the development of the mine is extensive, owing to condensation. Carbon dioxide is usually efficacious when other schemes fail, as the gas penetrates to every corner, driving out the air and smothering the fire as effectually as water would, moreover, the gas can be readily driven out of the workings when the fire has been extinguished.

THE SULMAN-TEED PROCESS of extracting gold from its ores is also known as the bromo-cyanide process. It depends upon the chemical reaction

$$Cy\ Br + 3KCy + 2Au = 2KAuCy_2 + KBr.$$

The inventors of this process claim for it that it is superior to the ordinary cyanide methods in the higher potential of cyanogen. The quantity of cyanogen bromide in solutions is determined by mixture with an excess of potassium iodide, and acidification with hydrochloric acid, during which iodide is liberated as follows:

$$Br\ Cy + 2HI = HBr + HCy + 2I.$$

The amount of iodide is determined by the use of sodium thiosulphate in the usual manner. A plant employing the Sulman-Teed process does not differ from the usual type of cyanide plant. The solution is made up in a single tank, containing about 7% bromide cyanogen, which is added to the ordinary KCy. solution, but an excess must be avoided, as potassium bromide is decomposed during its passage through the zinc. The amount employed should not exceed one-fourth the weight of potassium cyanide present.

TUFF is the name given to accumulations of volcanic ejectamenta on land more or less solidified by rain and surface waters. They are of various kinds, as for instance, quartz porphyry tuff, porphyry tuff, feldspathic ash. These are usually compact "claystone," colored white, buff, various shades of yellow, green, brown and other colors, often including quartz crystals, mica and organic substances. Tuff of this description is often hard and rings like pottery. Rhyolite tuff, rhyolite pearlite tuff, rhyolite pumice tuff and trachyte tuff are abundant in many volcanic regions. These occur as earthy masses of various colors, usually white or grayish. Often quarried and employed as a building stone. It may generally be easily sawn or cut out with an ax, and trimmed to the desired size and shape. Trass is tuff, formed from mud streams due to melting snows or rain. There are also phonolite tuff, andesite tuffs, basalt tuffs, diabase tuffs, etc. These rocks may or may not be stratified. Those deposited on land are usually massive and show little sign of stratification, but there are tuffs deposited under water which are generally distinctly stratified. Such material has been named tuffite, and tuffoid is the name given to tuffite that has been altered by regional metamorphism. In some regions tuffs are the bearers of valuable mineral veins. Silicified tuffs are reported, but are of rare occurrence.

VANADIUM was discovered in 1830 by Sefstroven, a Scandinavian chemist, who obtained the mineral from a specimen of iron ore taken from the mines at Taberg, Sweden. It was subsequently produced in considerable quantity from the slags from the Taberg blast furnaces. Vanadium has a specific gravity of 5.5 and is a light grayish white metal, of silver-white luster. Its reduction from pentoxide to the metallic state is accomplished by heating the oxide in the electric furnace, under the addition of reducing agents. It is insoluble in hydrochloric acid or aqueous alkalies, but is attacked by sulphuric acid and readily dissolved by dilute or concentrated nitric acid. When fused with caustic soda, hydrogen is evolved and sodium vanadate is produced. It is obtained from iron ores containing it by mixing the finely powdered ore with niter and heating the mixture in a fireclay crucible to complete fusion. The cooled mass contains the vanadium compounds in the form of potassium vanadate, which is then treated in boiling water, the solution thus obtained is filtered, nearly neutralized with nitric acid and mixed with a solution of barium chloride or nitrate, to precipitate the insoluble barium vanadate. This is separated from the liquid by filtration, washed with water and decomposed by heating with dilute sulphuric acid. The acid liquid thus resulting is then filtered from the precipitated barium sulphate, neutralized with ammonia, concentrated by evaporation on the water bath and cooled. Solid pieces of ammonium chloride are then introduced into the solution, when ammonium meta-vanadate, soluble in water but insoluble in a concentrated solution of ammonium chloride, gradually separates out after long standing. The vanadate thus formed is then filtered off, washed with a concentrated solution of ammonium chloride, dried and gently heated in an open crucible. Vanadium is often associated with ores of uranium. Vanadium may be recognized by the yellow color given to the salt of phosphorus bead in the oxidizing flame before the blowpipe. Vanadium pentoxide is worth about $1 per pound, the price having fallen since the discovery of considerable quantities of vanadium with uranium ores in Colorado.

Mining at the Homestake Mine.

The Homestake mine at Lead City, S. D., is the largest gold mining enterprise in the world. The original Homestake claim was staked in 1876. It is surrounded hy claims which lie in a helt or zone over 2000 feet wide and more than 10,000 feet long. The properties of the Homestake company include the Homestake No. 2, Giant and Old Ahe, Palmetto, American Flag, Clara, Big Missouri, Highland Chief, Golden Star, Golden Terra, Deadwood, Caledonia, Father De Smet, Justice, Belcher and numerous others. In the passing years these several mines, mostly owned and operated individually, have heen consolidated in groups and finally absorhed hy the central company—the Homestake—until these mines, noted in their day, have to a great extent lost their identity. The principal mines and mills of the group originally were the Homestake, at first with a mill of thirty-five light stamps, which was removed in 1878 and a mill of eighty heavy stamps huilt. This was followed by the Highland Chief with 120 stamps and the Golden Star with 120 stamps; the Caledonia had originally twenty stamps some distance from the mine, but later huilt a 60-stamp mill at the mine; the Golden Terra and Deadwood mines had sixty stamps each. These mines afterward were consolidated and the mills made one by the removal of sixty stamps of the Deadwood to the Terra mill. The Father De Smet had originally ten stamps, hut this mill was torn down and one of 100 stamps built. Many changes have since been made until now the Homestake company operates 900 stamps.

In describing the mining methods at the Homestake the Lead City Call says: The Star shaft was the first sunk hy the company that is now being used, and the only one in the ore hody, properly speaking. In sinking this shaft a station was cut every 100 feet and a level thus estahlished. A crosscut was then driven to the foot wall on each level. These crosscuts are usually 12 feet wide for douhle track. Commencing at 50 feet from the shaft a drift 24x12 starts off the main header, and one on each side of the latter on the north and on the south. These are continued with the ore hody until the latter is exhausted. Sixty feet farther west the same methods are pursued in the several instances until the foot wall is reached. Each level contains a douhle track drift to the Old Ahe shaft. These are used to transport ore from shaft to shaft.

Having blocked out the ore the next step is crosscutting. No. 1 is started ahout 60 feet north or south, as the case may he, of the main header, and is widened to 60 feet.

Timhering in the Homestake is hy the square-set system and sills are employed. These consist of 12 and 6-foot pieces of timber, the latter heing known as "ties." These are laid to form squares every 6 feet. These sills are laid on the floor and the space hetween sets is filled in with dirt. With the completion of these the standing of the sill-floor posts will be 8 feet high. These posts range in dimensions from 18 inches to 2 feet. The caps and ties are then put in place, forming the square set.

Lagging over consists in laying a floor of timher not less than 6 inches in thickness and 5 feet 10 inches in length, from cap to cap. In some instances these stopes extend a distance of ninety sets, and, having 60 feet to hreak to, long holes can he drilled with the machine drills, breaking large quantities of rock. As soon as stoping has progressed upward above the first or sill-floor set to warrant it, timher for the next is placed. This raising up is continued until eight or nine floors have been completed, depending largely on the condition of the ground, when a small raise is run to the next level and the work of filling in with waste is hegun. All that is necessary is to remove lagging, leaving the other timbers standing. When this has heen accomplished to the height attained the remainder of the ore is taken out to the next level. As the ore is hroken it is shoveled into mill holes left in the floor, the ore passing to the ore bins in the lower sets, whence by means of chutes it is drawn into cars for transportation to the shaft.

The next stope is started 60 feet from No. 1, thus leaving a pillar of solid ground 60 feet wide, and as the system is pursued on each level a solid pillar extends clear through, which holds the immense weight and makes mining on this large scale practicable. In time, probably years to come, after the levels have all heen worked in the manner described and the stopes filled with waste, the pillars may he removed, but up to the present time, owing to the immense hody of ore encountered, the cutting of pillars has not been attempted except in a very few instances.

The cost of timhering in square sets per ton of ore varies greatly, hut is estimated to range from 30 cents, under favorable conditions, as to cost of timber, character of ground, etc., to 50 or 60 cents under more expensive and less satisfactory conditions. The variahle cost of lahor also is important, as well as the size of timhers employed. Where very large timhers, as in this mine, are used the timber gang from necessity is larger than where the timbers are relatively small, more men being required to handle the large timbers, which are often 24 inches or more in diameter, weighing upwards of 800 pounds.

Stoping without timher, or the "hull pen" system, as it is called by the miners, is another method of mining these large ore bodies that has been practiced by this company during the past two years. The sills and sill floor timbers are put in one set high as in a timhered stope, and the hroken rock falls between the sets, with the exception of over the lines of track, where the rock is handled hy the carmen. The latter is lagged over and laced on the sides as a protection to the men taking out the rock below. The rock hroken accumulates so much faster than it can he utilized helow that the miners are enahled to work on top of the pile. The upward stoping is continued until not more than 20 feet still remains between the hack and the next level, when operations are suspended, and the rock thus hroken is drawn off. Here again the same methods are pursued as in a timhered stope, viz.: The running of a small raise and filling of waste, after which the remaining rock is removed.

Man-ways for the safety and convenience of the miners and the disposition of air pipes, etc., are provided in the stope next to the pillar. These manways consist of one square set of timber. In order to insure this set standing as the loose rock is drawn out, in addition to the hracing, holes are drilled into the pillar at regular intervals and a strong piece of steel inserted, the outside posts being tied to these by means of wire ropes. Each level contains a great many small raises, prohahly 4½ feet square, from level to level, to permit the escape of the gas and smoke.

The waste rock to fill the stopes is partly supplied by dead work, all the ground thus broken heing utilized for this. But the hulk of it comes from the open cut north of the Star hoist. In several of the upper levels, and as far down as the 400-foot level, raises have heen put through to the surface, and the rock as it is broken falls into these and is drawn out as desired, when it can he hoisted at one of the numerous hoists to the level where it is wanted. Considerable ore has also heen taken from this cut, heing hlasted out after the waste has been stripped from it.

Several years since, when the hoisting capacity of the Homestake was pushed to its utmost to keep the mills going, the estahlishing of ore hins in the mines was undertaken. These hins are started on timhers and widened upward as stoping is carried on to a certain height, when they are narrowed again as the level above is reached, leaving a hole sufficient to dump the ore from above. Each of these will hold 1000 tons of ore, and some more, thus enabling the management to have a reserve supply on hand sufficient to keep the mills running for several days.

The Homestake is not a wet mine as compared with some others, still considerahle water is encountered. The drainage is effected hy means of a large pump situated on the 1100-foot level. A hrick building, 60 feet long hy 20 wide, was constructed in a large chamher cut in the rock for this purpose. The walls are 2½ feet wide at the base and 2 feet at the top, and 10 feet in height. The roof is arched and at the highest point is 18 feet ahove the floor. A hrick building of these dimensions containing 300,000 hricks, 1100 feet below ground, is something unheard of elsewhere. A Reidler pump, with a capacity of 500 gallons per minute, has been installed within the structure and handles the water with ease.

Machine drills, run by compressed air, are used, there being ahout 200 of them.

Something like 150 miles of steel track is laid in the Homestake and eighty-five head of horses and mules are employed. All the main headings are lighted by electricity, as are also all stations. A sawmill at the Highland hoist is kept busy night and day cutting the timher, making wedges, lagging, etc.

The Homestake is now opened up to a depth of 1100 feet. At least 400 men on each shift (night and day) are employed.

The Homestake mine has a record of gold production exceeding $90,000,000. Of this sum $30,000,000 has been profits, $18,000,000 of which has heen dishursed to stockholders in dividends, and $12,000,000 in the purchase and betterment of property. The Homestake alone has paid over $12,000,000 in dividends in 296 successive monthly payments, covering a period of twenty-four years and eight months up to June, 1903.

The operations of the Homestake cover 2 miles on the strike of the lode, with twenty years of reserve ore explored in its territory—equal to 26,000,000 tons—ahove the 1100-foot level, the deepest exploration. The company now operates six stamp mills, with a total of 900 stamps, reducing 3600 tons of ore daily; and two cyanide mills of 800 and 1300 tons capacity, respectively, which treat the tailings from the mills direct. It has five working shafts equipped with steam hoists.

Regeneration of Cyanide Solutions.

In the article written by William Orr, on "Regeneration of Cyanide Solutions," which appeared in the issue of June 20, in the fifth paragraph it speaks of the regeneration of the H_2S from ZnS_2. This is an error and should have read; "The regeneration of H_2S (hydrogen sulphide) from ZnS (zinc sulphide)."

Filter-Press Treatment of Gold Ores and Slimes By Cyanide.

The treatment of finely slimed gold ores by the cyanide or bromo-cyanide process has, during the last few years, caused much discussion and experiment among the metallurgical engineers of this and other countries.

The process of filter-press cyanidation, first used in the Kalgoorlie gold fields of Western Australia for the treatment of the sulpho-telluride ores, has heen so far perfected as to prove the efficiency of the system on finely pulverized pulps, and to demonstrate that close extraction can he ohtained hy this means on talcy slimes.

The systems at present in vogue for crushing gold ores have for their first object the avoidance of the production of slimes—owing to the difficulty of treating the latter—hut it has been found that a stamp hattery or any other system of crushing will always produce a percentage (small or great, according to the character of the ores) of slimes that are not amenable to direct leaching treatment in vats by percolation or natural subsidence.

The decantation system for the treatment of slimes has proved successful on pulps of a talcose nature, but some difficulties have been experienced in the economical extraction of values, owing to the long period required and the heavy consumption of cyanide, the latter due to the excessive period of contact under agitation.

One of the first principles laid down hy Elsner is that "during the process of dissolving gold in cyanide solutions the presence of an oxidizing agent such as air is necessary." This is the underlying principle in the filter-press process of cyanidation.

On the Rand, South Africa, where operations in the percolation process have been conducted on an enormous scale, vats of as much as 900 tons capacity are sometimes employed, and the time required for treatment, including dissolving the gold and the final washing out of the solution remaining in the hed after the gold has heen hrought into solution, is from one to three weeks.

Where single percolation plants capahle of dealing with many hundreds of tons per day are in use, the large size of the plant required can he readily realized. Although the plant seems to be very simple in character, yet, owing to its extent, it is expensive, compared with a filter-press plant of equal capacity.

The latter process for capacity depends largely upon the fact of a high pressure, urged or forced filtration, that accomplishes in a little over an hour the results in extraction that are gained in ten or fifteen days hy the percolation or natural subsidence systems. At this rate a filter press, capahle of dealing with five tons of ore at each charge, would be equal in output to a percolating vat of 1000 tons capacity. This, of course, is in the treatment of slimes.

There are cases where the slimes contain a good deal of sharp sand and are more permeahle, when satisfactory results are obtained by percolation; hut in the case of the filter-pressing system it does not matter how slimy the ore, if proper precautions are taken to produce uniformly permeable cakes, a high percentage of extraction is the result.

If other than uniformly graded sharp sand pulp material is pumped or dumped into a percolating vat, the bed becomes more compacted in some parts than in others, thus leaving some porous and some dense parts. Then when the solvent liquor is pumped on to such percolator with its bed variahly dense and porous, what may he called "short circuiting" takes place, that is to say, it passes readily through the more porous parts of the bed, leaving the more compacted portions untreated, or very slightly acted on, by the cyanide solution.

In the case of filter-press treatment, means are taken to insure the most perfect homogeneity and uniform permeability, or porosity, of the cakes of ore deposited in the chambers of the filter press.

In the filter press of the American Filter Press Extraction Co. of Denver, Colo., a method is provided to secure the required filter bed of uniform permeability. This bed admits of the solution contained in same, both as to dissolved gold and cyanide, being readily displaced without, or with very little, admixture of the wash water.

In dealing with material of slimy character, the percolation process is not advantageous, and the results will be more imperfect the more slimy the material. Percolation is alone suitable for dealing with sharp sands, in which the difficulties of forming a uniformly permeable filter bed are a minimum.

Experience has shown that the most of these materials have yielded readily to the filter-press process and given a high percentage of gold extraction.

In general, with regard to percolation and natural subsidence processes in the treatment of slimes, the principal defects are low per cent of extraction of total gold, owing:

(a) To imperfect methods of hringing the gold into solution.

(h) To short circulting of the wash water through

the more permeable part of the bed or ore; and in the case of subsidence.

(c) To loss of gold remaining in solution in the solvent, in which the particles of ore are suspended at the termination of the process.

(d) Further, the loss of chemicals in both processes by dilution is very great.

A filter press is essentially a high-pressure arrangement of filtration, a forced or urged filtration, acting under hydraulic pressure. In this process there are available from 100 to 200 feet head of liquid against a few feet in the percolating vat. It is also practicable in the case of the filter press to increase the pressure to any extent which may be desired.

The saving of time is a matter of prime consideration. This is accomplished, not only by the high pressure or forcing referred to, but by reason of the shallow filter beds, in compact form, and the extended area of same, resulting from the use of a battery of filter cells.

The chambers of the press can be fed so rapidly that the filtering cells are filled with the cake in so short a time that no subsidence takes place; and the slimes are charged into the filter press in such a state of concentration that subsidence under any circumstances would be greatly retarded.

Another improvement is an increase of the depth of the filter chamber.

It was found advantageous to increase these chambers to two or three inches. This proved to be important, inasmuch as the production of cakes of uniform permeability could never be assured in shallow chambers when working with such freely filtering material.

The cakes require to be built up in the filter cells under pressure in order that they shall be uniformly coherent. When the cakes are built up in this fashion under pressure, it is found that they are much more uniformly porous and homogeneous in character.

For the purpose of expeditiously feeding the filter presses large feed pipes are employed, and a system of forcing by means of compressed air from an air accumulator or storage vessel, in which a considerable volume of air under high pressure is stored.

The next point of importance with reference to securing the production of a uniformly permeable cake is through the mixing of the material before it is delivered into the filter press, so as to secure homogeneous slimes having both the fine sandy portion and the finer slimy portion so mixed together as to be uniform in character. This material when forced into and instantly deposited in the cells of the filter press forms uniformly permeable cakes, filling the battery of cells from end to end of the machine.

Attention has also been paid to the matter of the preliminary solution of the gold in solvent chemicals before treatment in the leaching press. For this purpose two different systems of agitating vats are provided. The first is a special form of mixing vessel by means of which a rapid circulation of the liquid from top to bottom is obtained, thus avoiding any possibility of subsidence and securing a homogeneous mixture of the slimes, as well as the direct contact of the gold with the solvent.

This machine is a circular, comparatively shallow vat, fitted with a central vertical shaft, driven by beveled gear placed either above or below the vat, the vertical shaft carrying horizontal radial arms attached, which revolve in the pulp at a speed commensurate with the size of the vat or amount of pulp to be agitated.

Another device is one in which the pressure tank is used as an agitator.

A worm-shaped or voluted pipe perforated with mall holes is placed through the center of a specially shaped pressure tank, through which air under mesium pressure is forced, giving the pulp a swirling or rotary action, which mixes the whole of the particles and results in a thorough homogeneity of the mass.

In addition to the process of agitation in the latter device, there is added the factor of aeration for the purpose of insuring the presence of a sufficient amount of oxygen to enable the cyanide to efficiently do its work. According to Professor Elsner, what takes place is shown in the following equation :

$$4KCy + Au_2 + H_2O + O = 2\,(KAuCy_2 + 2KHO.$$

(Cyanide Potassium) (Gold) (Water) (Oxygen) (Auro Potassic Cyanide) (Potassic Hydrate)

In the case of telluride and highly arsenical ores, it has often been found necessary to apply a roast before attempting to extract the gold. If such ores are finely pulverized, and no copper present, an extraction of 90% to 98% is often obtained by the filter press without roasting. In some cases where arsenical pyrites in large quantities are present, it may be necessary to obtain a preliminary extraction by concentration.

At some mines there are large accumulations of slimes which have become air dried and are ready for immediate treatment. On the other hand, it is desired to treat slimes as they come from the battery or mill to avoid accumulations.

Accumulated slimes are in most cases in a semi-dry condition, requiring preliminary mixing with water, or solution, to enable them to be forced into the press in pulp form, whereas slimes as they come from the battery can be treated direct. In both cases, the pulps have the liquids eliminated immediately they are forced into the filter press. This is necessary to avoid the loss of chemicals.

In the treatment of dried accumulated slimes, the material to be treated is delivered from the elevator chute into a circular vat containing radial agitator arms, moving at a speed of, say, thirteen revolutions to the minute.

Simultaneously to the discharge of the material into the vat, there should be a pipe conducting weak cyanide solution which will wash the material from the chute of the elevator into the vat. The amount of liquid should be so arranged as to give a pulp containing about 45% solids. The nearer the pulp approximates an equal proportion of liquids and solids the better it is for after reatment.

The mixer is kept charged and working continually, being kept in its normal working condition fully charged.

From the mixing tank the slimes, with the whole of the gold brought into solution in the cyanide, and in a uniform and homogeneous condition, are discharged into the pressure tank or forcing receiver. The pressure tank is specially constructed to contain about two-thirds more than the capacity of the filter press when fully charged. The slimes, on entering the receiver, are agitated with the central perforated pipe agitator, the period of which agitation is variable, according to the composition of the ore. The slimes are then forced by compressed air into the filter press at from sixty to eighty pounds per square inch, according to the character of the slimes.

The time required to charge the filter press is from three to eight minutes, and it is important that a longer time should not be employed for this purpose, in order to avoid any settlement of the slimes in the chambers of the press.

The time employed in filling the machine should be as short as possible. Assuming the operation of charging the filter press with slimes takes five minutes, the next operation of alternate washes of strong and weak solutions under air pressure, and the washing or displacing of the gold-bearing solution from cakes, will require about thirty minutes, so that the whole operation of charging, leaching and washing will take approximately from one-half to three-quarters of an hour. This assumes that the slimes to be worked are of an ordinary porous character. If they are more of a sandy nature, less time will be required; if of a plastic and slimy nature, a longer time will be required, depending upon the condition of the material.

The forcing of the solution and wash waters through the press may be done either through the pressure tank or specially constructed forcing receiver, or by pumps. It is best to have separate zinc boxes for the different strength (strong and weak) cyanide solutions.

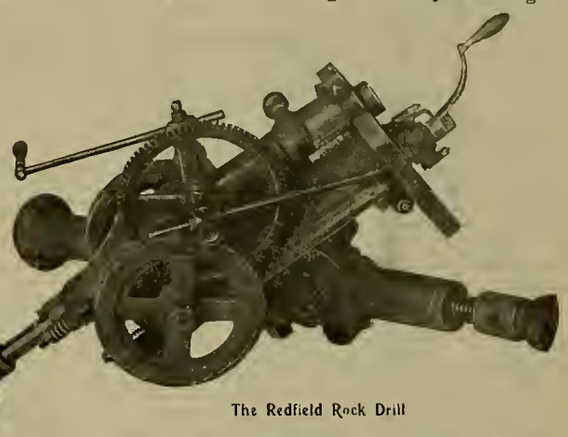
The contents of the filter press are then discharged into tip trucks or on to conveyor belts by unscrewing the press and lifting the frames and plates apart. This completes the operation.

The discharging of the filter press and adjusting the cloths for the next working will take from twenty minutes to half an hour. This makes the whole operation of working and filling the press to be about one and a half hours, but, for continuous working, it is found in practice that it is not safe to calculate on less than two hours, so that, with continuous working, the daily output is from ten to twelve charges for twenty-four hours.

An air compressor of suitable capacity and an air receiver are used to work the forcing and washing arrangements. In the treatment of dry slime accumulations it would be advisable to pass the slimes through a coarse screen, prior to elevation into the mixing tank. This will remove the rubbish that invariably collects in all slime dumps (pieces of wood, ashes, stone, bagging, etc.)

This screening of the slimes has proved to be important, as a good deal of trouble has been occasioned on account of rubbish getting into the channels of the filter press.

The whole of the platform and launders leading to the mixing tank should be placed at a suitable incline, to allow slimes to flow quickly away, and a point of importance in mixing the slimes is to maintain a constant relation between the quantities of solid slimes and cyanide liquor.



A good plan to determine the strength of the slimes is to use a hydrometer of special construction, and particular care should be taken with regard to this, as otherwise, if the slimes are too weak, the forcing receiver will not hold the charge for the press.

It is of the utmost importance that there should be no stoppage in charging the filter press, but that the whole charge should be blown in with one blow from the forcing receiver.

(TO BE CONTINUED.)

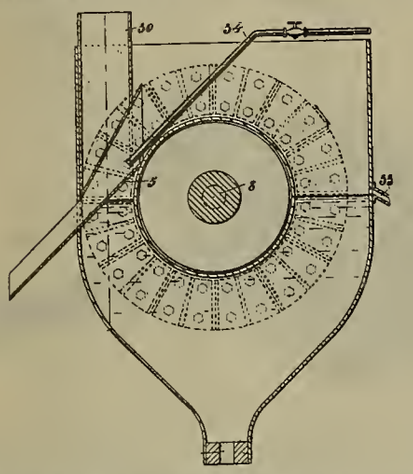
Redfield Rock Drill.

The Redfield hand-power rock drill, as now made, is of steel, each part interchangeable, one machine being a duplicate of the other. Seven-eighths octagon steel will fit the chuck without swedging the shanks. The drill has an extra long double-thread feedscrew, which permits the operator to crank the drill back rapidly and change the steel readily. It also has a universal joint, which by giving one nut a half turn, the drill may be tilted to either side out of the line of the drill hole, so that long steel may be changed without loosening clamp bolts; the drill can be tilted back in alignment easily. It is operated by a rotary movement of a hand crank, without any jar or shock to the operator, by one or two men. It is claimed by the manufacturers that double the work can be accomplished with this drill over hammer and bit with less exertion. The drill delivers 3½ strokes for each revolution of the crank, or from 175 to 275 blows per minute when running at ordinary speed. It has a tension lever, by which one can regulate the blows to strike hard, medium or light without stopping the drill. The machine is supplied with an automatic feed to minimize friction and to enable the operator to determine when his bit is dull or broken, for it will not feed up if the bit is not cutting. The Redfield hand-power rock drill, illustrated herewith, was invented by J. H. Redfield and is manufactured by the Redfield Drill Co., 1606 Blake St., Denver, Colo.

The Redfield Rock Drill

Weinland Mechanical Cleaner.

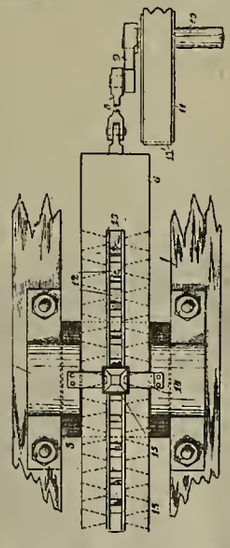
It would seem unusual that scale would be allowed to accumulate in boiler tubes to the thickness of an inch, yet the Lagonda Mfg. Co. of Springfield, Ohio, reports cases where this much is found in boiler tubes which they are frequently called upon to clean. The cut shown herewith represents one of over 215 tubes in the boilers of a street railway company in the South. The engineers were surprised. The water was bad, and, having use for all the power the boiler would furnish, without any opportunity to shut down, the scale accumulated before they knew it. They were about to cut out the tubes when their attention was called to the "Weinland" mechanical cleaner, which they purchased, and in a short time, with little trouble or expense, were enabled to clean out the tubes without injury to them, leaving the inside in good condition. The firm referred to makes a full line of cleaners for all kinds of boilers, notably the turbine cleaner. In the majority of cases, they say, this turbine cleaner does the work, and they are ready at all times to send these machines on approval. They make a business, also, of cleaning boilers by contract, and will be glad to enter into correspondence with anyone having any inquiry to make about such work. A line to the Lagonda Mfg. Co., Springfield, Ohio, will bring its illustrated catalogue, showing cleaners at work and other interesting matter.



Scale in Boiler Tube.

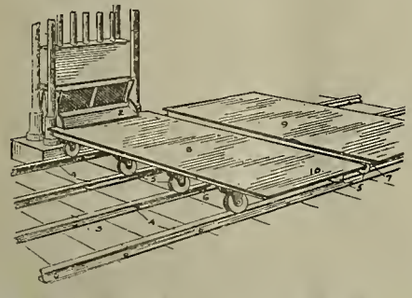
Mining and Metallurgical Patents.

PATENTS ISSUED JUNE 23, 1903.



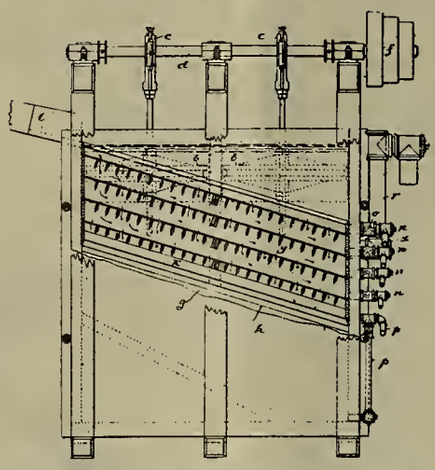
Specially Reported and Illustrated for the MINING AND SCIENTIFIC PRESS.

MAGNETIC ORE SEPARATOR.—No. 731,443; K. V. A. Eriksson, Falun, Sweden.



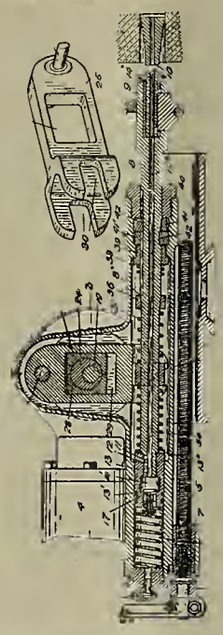
In magnetic ore separator, combination of separating chamber formed by vertical plates, transverse opening in separating chamber, rotatable shaft inserted through opening, means for rotating shaft, electric winding on shaft, means for feeding electric current to winding, two disks rigidly fixed to shaft, number of magnet poles on each disk adapted to run close to walls of separating chamber, feeding channel entering with lower end between magnet poles, and discharge channel for magnetic material traversing feeding channel.

MAGNETIC SEPARATOR.—No. 731,446; A. E. Forsgren, Falun, Sweden.



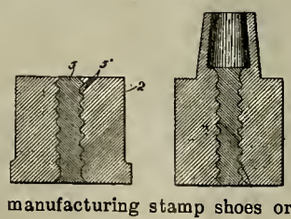
Combination with magnetic ore separator having primary and secondary magnet poles movable in relation to each other, frame arranged to move between primary magnet poles, two rows of secondary pole pieces fixed opposite each other in frame, and intermediate row of openings in frame, each opening arranged between one pair of secondary magnet poles.

ORE-MILLING APPARATUS.—No. 731,634; G. R. Tuttle, Grass Valley, Cal.



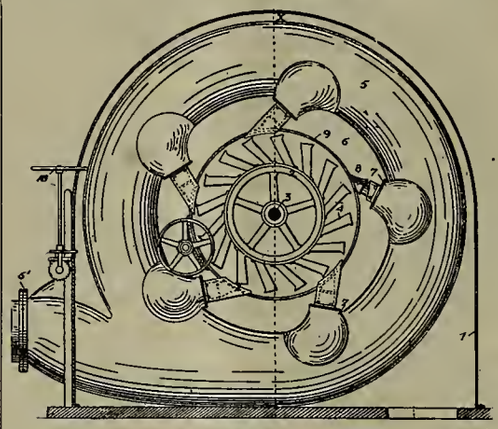
An ore-milling apparatus comprising stamp mortar, discharge lip projecting therefrom, parallel tracks arranged transversely to mortar, independently movable tables working thereon, amalgamating plates carried by table, tables being arranged that movement of one table into field of action forces other table with amalgamating plate therefrom.

APPARATUS FOR SIZING ORES OR FOR OTHER USES.—No. 731,522; S. R. Swain, El Paso, Tex.



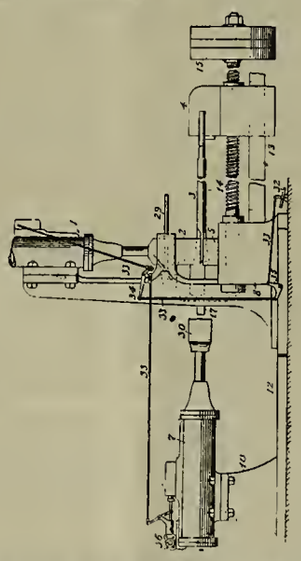
Combination of tank having partition in upper part to form sieve compartment and plunger compartment communicating at lower ends, plurality of differently sized sieves supported one above tbe other in sieve compartment which sieves are closed against entrance of water except through openings thereof, vertically reciprocating plungers in plunger compartment, means for feeding material to be sized and water to upper sieve, and overflow pipe located outside the tank and leading from plunger compartment below normal water level.

ROCK DRILLING MACHINE.—No. 731,569; J. G. Heimrich, Seattle, Wash.



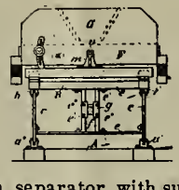
In rock drilling machine, combination with frame having cylindrical body portion, ram reciprocally mounted in body portion, crosshead loosely mounted on ram, spring connections between crosshead and ram, lever pivotally connected adjacent to one end to frame and provided with elongated aperture intermediate of its length, sliding connection between crosshead and end of lever opposite pivotal end, shaft extending transversely through frame, motor secured to frame, and connection between motor and shaft; of a sleeve loosely mounted on shaft and passing through aperture of lever, eccentric integral with sleeve, and positioned within aperture, boxing for eccentric, and means to couple shaft to sleeve.

METHOD OF MAKING STAMP SHOES OR DIES.—No. 731,748; W. Brinton, Highbridge, N. J.



Method manufacturing stamp shoes or dies, consists casting body with heat-equalizing opening, having irregular wall surface, heat treating body by heating and cooling it, and pouring into opening of cooled body molten metal to form plug which as it solidifies, interlocks with walls of opening and owing to contact with cooled wall of opening is toughened;

WATER NOZZLES FOR IMPACT WATER WHEELS.—No. 731,570; G. J. Henry, Jr., San Francisco Cal.



In combination with impact wheel, water nozzle provided with series outlet openings, nozzle tip for each outlet opening, plates secured to nozzle opposite sides of nozzle tips and projecting outwardly to point beyond discharge ends of tips, inwardly turned flanges at free ends of plates, and cut-off slidable between plates and between flanges thereof and discharge ends of nozzle tips.

PROCESS OF FORGING ROCK DRILLS.—No. 731,727 W. W. Word, Soulsbyville, Cal.

Process forging and shaping rock drills, which consists swaging end of drill blank to bring it to flaring cruciform shape having wings right angles and angular depressions between, then swaging terminal portion to condense and shorten wing corners, and finally forming cutting edges of wings by means of endwise blows delivered thereon through suitable appliances from center successively outward, which reduce and draw redundant metal from center outward, fill out corners, and form finished V-shaped solid edges all lying in same plane.

MACHINE FOR SEPARATING ORES.—No. 731,438; D. S. Decker, New York, N. Y.

Combination in separator with supporting frame, oscillating platform arranged over frame, and swinging standards for supporting platform and permitting oscillation, of trunnioned separator bed carried by platform, framework interposed between platform and separator bed and having bearings for receiving trunnions of separator bed, vertical screws provided to platform and arranged for changing angle to horizontal of framework, and dash pots and pistons arranged to cushion oscillations of platform and parts carried thereby.

Mount Sicker Mining District, British Columbia.*

Written for the MINING AND SCIENTIFIC PRESS by W. M. BREWER, E. M.

The early history of the Mount Sicker mining camp has associated with it a considerable amount of luck, because the first discoveries made on that mountain of copper ore were not the result of any systematic prospecting nor the result of the observations made through a geological survey. In fact, so far as the writer can ascertain, this mountain, which is situated in the vicinity of the agricultural district of Cowichan valley, had never attracted any attention other than that of sportsmen until after a timber fire, about 1896, which left a portion of the summit and side of the mountain bare.

Some hunters were attracted by the discoloration of the rocks, and, more to satisfy their curiosity than otherwise, carried away some specimens of the outcroppings, which they had assayed. As it was found that these samples carried good copper values, the attention of some prospectors from Port Townsend and Washington was directed towards the mountain.

As a consequence, several mining claims were located, amongst them the Lenora and Tyee.

During 1898 several prospectors visited the camp, and quite a number of mineral claims were located both on Mount Sicker and Mount Brenton, which is situated to the west of Mount Sicker, the Chemainus river flowing between the two. Until 1899, no really serious attempt at development of any of the claims had been made.

The owners, as a rule, were without any capital; there were no roads to the mountain, and all supplies had to be packed in on men's backs.

During that year the owners of the Lenora mineral claim were successful in securing capital to develop the property, and also in securing aid from the Government to build a wagon road up the mountain. As soon as this road was completed, sample shipments of ore which had been taken out during the progress of development were made to the Tacoma and Everett smelters in Washington. The results from these tests proved so satisfactory that it was deemed advisable by the management to take out all the available ore and ship it, notwithstanding the fact that the freight by wagon haul to the Esquimalt & Nanaimo Railway, at Westholm Siding, added to the railway freight and cost of transportation by steamer from Oyster bay, on the east coast of Vancouver Island, to Tacoma, made the total cost for transportation alone about $5 per ton.

During the winter of 1899–1900 the management constructed a surface tramway with wooden rails from the railway to within about 2 miles of the mine, because the heavy rains made hauling practically impossible over that portion of the wagon road. The policy of continuing to ship all the available ore was continued, and the shipments often exceeded sixty tons of first-class ore per day. The second class was dumped near the mouth of the tunnel, through which the work was carried on.

About a year later the management decided to replace the tramroad by a narrow gauge railroad, built direct from the mine to the same point as where the tramroad connected with the E. & N. Railway.

In December, 1901, the management of the mine made arrangements with Messrs. Breen & Bellinger of Butte, Mont., to build a smelter on the townsite of Crofton, situated on the shore of Oshorne bay, about 11 miles from the mine, and made a contract for the smelting of the product.

In October, 1902, this smelter plant was completed and the furnaces ready to blow in. The plant is one of the most modern in the West, has a total capacity of about 750 tons of ore per day, and converts the matte into blister copper.

About the same time the management of the mine turned the property over to mortgagees and the mining company went into liquidation, after having mined a total tonnage of all grades of ore of 60,000 tons, about 20,000 tons of this being first-grade shipping ore and balance second grade or cullings.

During the time that these events were transpiring with regard to the Lenora mineral claim, the Tyee mineral claim had been acquired by an English company, designated as the Tyee Copper Co. The management of this company pursued an entirely different policy from that followed by the management of the Lenora. This company was organized first with $25,000 cash for a prospecting fund and later with $100,000 cash in the treasury; the management commenced to systematically develop the property, in order to block out "ore in sight," and determine the capacity of the mine, extent of the ore bodies, grade of the ore and its characteristics.

This work was commenced during the spring of 1900, previous to which time a vertical prospecting shaft 200 feet in depth had been sunk, in which was exposed an ore body presumed to be an extension towards the east of the ore body being worked in the Lenora mine.

Mining machinery was installed and sinking was commenced on a two-compartment working shaft in the country rock, about 100 feet or so from the other shaft and within about 200 feet from the eastern boundary of the Lenora mine.

This shaft was carried down 235 feet, or to the same level as was reached by the first shaft, the difference in measurement being the difference in altitude between the collars of the two shafts.

From the bottom of the vertical shaft a crosscut was made in the expectation of intersecting an ore body; but, owing to the fact that the ore bodies are lenticular in structure, the result desired was not accomplished until an upraise had been made some 20 feet, when the lower extremity of a lens of ore was encountered.

The next work done by the management was opening a level 135 feet below the collar of the shaft. A short crosscut was run to the south which intersected ore, and this being continued, an ore body over 30 feet in width was crosscut before the foot wall was reached. Drifting was then commenced and driven both to the east and west along the foot wall.

During the summer of 1902 the management decided to erect a smelter having a capacity to treat about 150 tons of ore per day, at the town of Ladysmith, on the shore of Oyster bay, and on the main line of the Esquimalt & Nanaimo Railway. Because no satisfactory arrangement could be made to haul the ore from the mine to the railway by means of the Lenora narrow gauge, it was decided to install an aerial tramway about 3½ miles in length from the top of Mount Sicker to a point on the E. & N. Railroad about 10 miles from Ladysmith.

During the early fall this tramway was put in operation and an average tonnage of between 3000 and 4000 tons per month have been since transported over it.

In December, 1902, the smelting plant was completed and the furnace blown in. Since then this smelter has been treating an average of nearly 150 tons of ore per day. The matte produced is not converted in the plant, but is at present being shipped to the Tacoma smelter, where a converter plant was installed during 1902.

The development work which has been carried on at the Tyee mine systematically has resulted in there being to-day fully 100,000 tons of ore in sight blocked out above the 200-foot level. In driving to the west on the 100-foot level from that station it was found that the ore body maintained continuity to within some 60 or 70 feet of the boundary between the Tyee and the Lenora, and in driving to the east it was found that, although the ore bodies lay in lenses, these overlapped each other, so that practically the entire 900 feet of drift has been driven through ore all the way, because, although breaks occur between the lenses, yet it has been demonstrated that, whenever the drift has been driven through the barren rock, forming one of these breaks, by crosscutting to the north another lens has been exposed.

By means of upraises driven from this level, it has been determined that practically the same conditions as to structural features prevail when a vertical section is considered, as have been demonstrated to exist when the horizontal section is considered.

By upraising from the 200-foot level it has been determined that the ore bodies apparently maintain their continuity without a break between the 100 and 200 levels.

As the main drift has been driven towards the east and as the summit of the mountain is situated in that direction from the shaft, the backs above what is the 100-foot level at the shaft have increased quite rapidly towards the east, so that under the summit the level of the drift is really 245 feet below the apex of the mountain. The working shaft has been carried down to a depth of 435 feet. The foregoing is a brief history of the development work which has been carried on in the two most prominent properties on the mountain.

The development on other properties has been limited to assessment work, except on the Richard III, Key City and Copper Canyon group of mineral claims. The first named of these adjoins the Tyee on the east, and the development work performed on it has exposed a body of ore similar in character to that mined on the Tyee and Lenora mines. The Key City joins the Lenora on the west, and, although a shaft has been sunk to a depth of about 300 feet and a long crosscut tunnel run, intersecting the shaft at the 200-foot level, yet no ore body of importance has been exposed. The Copper Canyon group adjoins the Key City on the west and comprises three mineral claims and a fraction. This property is situated on the western slope of Mount Sicker and eastern slope of Mount Brenton, having a total length of 4700 feet. The Chemainus river, which flows between the two mountains, crosscuts the formation, and an examination of the bed of the river at low water shows that a mineralized zone exists of considerable width and apparently the same zone as that in which the Tyee and Lenora ore bodies occur. The bed of the river has an elevation about 1400 feet below the summit of Mount Sicker and about 3000 feet below the summit of Mount Brenton. A considerable amount of development work has been done on the Copper Canyon group, consisting chiefly in tunneling; but as the tunnels, although driven for drifts, have been driven in the schist rather than in the ore, it is impossible to express any more favorable opinion than that this group of claims form a promising prospect with possibilities of developing into a mine.

GEOLOGY.—The geological formation of Mounts Sicker and Brenton is quite different from that of most of the mineralized zones on Vancouver Island. Whereas most of the deposits of copper ore on the island occur in the formation classified by the late Dr. Dawson as the "Vancouver series," which comprise not only the entire mass of volcanic rock, but also the crystalline limestones, the deposits on Mount Sicker and Mount Brenton occur in a schistose formation and lack all the characteristics belonging to contact deposits, in which class the majority of the other ore bodies on the island should be included.

The schists on Mounts Sicker and Brenton, in the opinion of the writer, are metamorphosed slates or argillites. They are to some extent graphitic in character and in portions of the belt only partially crystalline. Dikes of igneous rock occur as intrusions throughout the district; some of these are porphyritic in structure, and all, so far as the writer has observed, are felspathic and basic.

The conditions in this belt, so far as the vicinity of Mounts Sicker and Brenton are concerned, indicate a considerable disturbance from volcanic movements during the period when these intrusive dikes were thrown up; that at that time the slates were tilted to an almost vertical angle, considerably contorted and subjected to great pressure, and at the same time there occurred an extensive shearing movement. Slickensides are very frequently met with in the underground workings, not only along the walls which form the boundaries of the ore bodies, but often in seams through the ore itself. As a result of pressure and shearing, wide fissures having lenticular structure were opened, with their lines of strike conformable with the line of schistosity of the country rock. Some of these lenses are quite extensive in width and length, as well as vertical measurement, while others are almost insignificant in their extent.

Development has demonstrated that the widest and most extensive lenses occur at the higher altitudes and on the Tyee and Lenora mineral claims; while on the level of the river, although the crevices filled with mineral are quite numerous, yet so far none possessing such extent as have been opened on the Tyee and Lenora ground have been found. There would appear to be reason, though, why extensive lenses should not occur at deeper levels than have been so far explored by workings. Certainly the movements which produced the schistosity and opened the fissures which have been exploited on the Tyee and Lenora claims were very deep-seated in their origin, and, unless lateral pressure had been evenly distributed at deeper levels and of such force as to squeeze the schists quite closely together, there is no reason to doubt that as equally productive ore bodies will be found in the deeper levels as have been found near the summit of Mount Sicker.

So far as it has been explored, the belt of schist which crosses Mounts Sicker and Brenton extends to the east to the vicinity of Maple bay and to the west an unknown distance beyond the summit of Mount Brenton. In width its exact measurement has not been determined; but locally on the mountains mentioned its maximum width is probably about 1200 feet. There is evidence that west of the Lenora mineral claim the belt of schist has for some distance been pushed over to the south from its general course; but on the Victoria claim, to the west from the Key City, the belt has assumed its normal course, nearly east and west, through that claim across the Chemainus river and into Mount Brenton.

On the west coast of Vancouver Island the Gordon river for quite a distance flows through a similar belt of schist; but whether this has any connection with that of Mounts Sicker and Brenton is a question the writer is not prepared to answer unless he had traced the belt from one point to another.

The occurrence of a wide vein of quartz, which extends across Mount Sicker to Mount Brenton and maintains persistent continuity, is a noticeable feature in studying the geology of the district. So far as the surface indications show, this vein of quartz appears to form the northern boundary of the mineralized zone.

On the Tyee and Lenora claims a second ore body has been exposed in the underground workings to the north of the main ore body. This is a body of quartz ore in which have often been found specimens carrying quite high gold and silver values. Its thickness is variable, and the same rule applies to its values.

The character of the ore mined from the Tyee and Lenora claims is a chalcopyrite, the gangue being pyrite, baryta and zincblende. The ore carries an average of about $5 in gold and 5% in copper (dry), with variable silver values per ton.

The smelting facilities for treating the ores of Vancouver Island are most excellent at the present time, and especially accessible to the various mining properties in the eastern portion of the island.

The smelting and converter plant erected by the Northwestern Smelting & Refining Co. at Crofton, on Oshorne bay, has already been described in detail in many of the technical journals; but the smelting plant erected by the Tyee Copper Co. at Ladysmith,

* See illustrations on front page.

on Oyster bay, (see illustration, page 1), a few miles farther up the coast of the island, has not yet been so described. Therefore the writer deems it proper to give the following description in the present article:

The Tyee Co.'s smelter was built after the plans designed by Thomas Kiddie, the smelter manager, with a capacity of about 200 tons per day; but the power house, smelting shed and dust chamber have been built for a capacity of 600 tons per day; so that only the additional machinery will be required to treble the capacity of the works. The ground between high-water mark and the track of the Esquimalt and Nanaimo Railway has been laid out in terrace form to give a gravity system throughout. The buildings are situated on the 37-foot level above the sea, and have been placed sufficiently far back into the hillside to admit of the installation of a converter plant. Two spurs from the Esquimalt & Nanaimo Railway have been built on the smelter property, entering it on the east—the lower one to the 37-foot level, for the shipment of matte, and the upper to the 51-foot level (the level of the charging floor), for the delivery of coke and coal. At the rear of the smelter buildings, and constructed so that the ore is dumped into ore buggies, on the 51-foot level, are the bins into which is dumped the burned ore, hauled from the roast piles. These bins have a capacity of 1000 tons and are connected with the roast piles, which are situated to the west, by a tramway about 2000 feet in length. (See illustration, page 1)

The machinery for the sampling mill is all on the ground, but the site has not yet been selected—the question being whether it is more desirable to erect it near the smelter or at the roast yard.

The ore is delivered from the bunkers at the terminal of the aerial tramway into bottom-dumping cars on the side track of the E. & N. Railway. From there it is hauled to bunkers at the roast yards, which have a capacity of 1600 tons. These bunkers or bins are furnished with automatic dumping gates and dump the raw ore into tram cars, from which it is dumped onto the roasting piles. The roast yard is arranged very systematically. There are a series of six permanent trestles, placed 60 feet apart and running from north to south. At right angles to these trestles six trenches have been dug, 4 feet deep and 40 feet apart, thus dividing the yards into beds 60x40 feet. In each trench a tram track has been laid and the roast heaps are built up parallel to these tracks, so that when the roasted ore is being removed the men shovel from both sides of the heap into tram cars run on parallel tracks. The trestles are built about 8 feet higher than the floor of the foundation for the roast heaps, and the ore is spread over the beds by means of a traveling bridge, placed between and at right angles to the permanent trestles. This bridge is so constructed as to run on rails and can be moved from end to end of the roast yard at will.

The traveling bridge was invented by Thomas Kiddie, the smelter manager.

By placing the roast heaps so far from the smelter and the town of Ladysmith, all inconvenience and annoyance from the fumes have been removed.

The smelter building is 81 feet in length by 51 feet in width. The charging platform, covered with steel plates, is 14 feet above the furnace floor, and is carried on cast iron columns with concrete foundation. A ventilator, 6x10 feet, extends the full length of the building and gives ample ventilation. The water-jacketed furnace, 42x120 inches, built by the Allis-Chalmers Co. of Chicago, Ill., is provided with fourteen 6-inch tuyeres and stands at the west end of the building. The slag is granulated as it flows from the settler and is carried in a flume into the lagoon.

At the east end of the smelter shed are two matte bins, each with a capacity of forty tons, a bucket elevator, matte sampler, one 7x10 Blake crusher, sample grinder and hoist elevator.

The engine and boiler house are 60 feet distant from the smelter shed and to the east of it; the dimensions are 70x50 feet. In this building are an 80 H. P. boiler of the return tubular type, No. 7 Connersville blower, an Allis-Chalmers (Corliss) engine and an electric light engine and dynamo. The power is transmitted from the power house to the smelter shed by means of a rope drive.

The water supply for the works has been provided by the E. & N. Railway Co., who have constructed a storage tank on the west side of their track, which is supplied through a flume 1 mile in length from the head of Rock creek. The railway company has since constructed a flume 4 miles in length in order to take the water supply from a source which has never been known to fail during the hottest and driest summers, and thus insure the smelter company against having any difficulties to contend with.

The assay office is located to the east of the smelter and has a frontage of 46 feet. It is divided into three rooms, with a furnace room 20x16 feet in the rear. In the furnace room is a 30-foot stack divided into four compartments, while on either side are located the muffle furnace of the most improved type and a sand bath with a hot-air oven; all are fired from one side, while the openings are in the assay and analytical rooms, respectively. In front of the stack stands a melting furnace, 16 inches square inside measurement, which is used for experimental purposes.

The Utilization of Furnace Slag.

Written for the MINING AND SCIENTIFIC PRESS by R. SCHORR, M. E.

Considering the mere enormous amount of slag made in metallurgical processes and the difficulties and expense which its disposition in many locations necessitates, in course of years, the subject of utilizing this waste product is of great economic importance. The products made from furnace-slag possess superior qualities and they are used to a large extent in the smelting works themselves, and find also a ready sale in cities and surrounding settlements.

The slag from iron furnaces of various descriptions is of predominant importance, and its composition is very similar to that of a hard fusible glass. It is a safe estimate to assume that in European iron making, for every ton of pig iron produced about one ton of slag is obtained, while in American practice it will be nearer to half a ton of slag per ton of iron. Estimating the American iron production alone to be 16,000,000 tons per year, about 8,000,000 tons of slag would be available. The most important and valuable slag products are slag bricks, slag cement and metallic. The casting of slag bricks and blocks is an old established practice, but the bricking of granulated slag on a commercial scale is of a more recent date, i. e., its thorough practical and financial success is of a more recent date. In the year 1859, the Georgs-Marienhutte Co. at Osnabruck started a slag brick plant, using lime mortar as binder and hand forms for molding. The bricks were fairly good, but their manufacture too slow and expensive. With the improvements in ordinary brick presses conditions changed somewhat, but the quality of the bricks still remained not quite satisfactory, as unslacked particles of lime were present in the mixture which slacked afterwards in the brick. This disadvantage led to the closing of the works, but their manufacture was resumed in 1890 with slag cement as a binder. The new process proved a complete success, which is illustrated by the fact that the production of slag bricks at Osnabruck increased from 5,000,000 in 1893 to 15,000,000 tons in 1898. The manufacture of such pressed slag bricks is very simple and about the same whatever binder is used. The slag discharging from the furnace is granulated by a stream of water which is running with high velocity through a narrow trough, forwarding it at the same time to a settling pit. The further arrangement may be to scoop the slag up by means of a bucket elevator and to discharge it into bins, wherefrom it may be drawn into hopper railroad cars to be forwarded to the briquetting plant. While in the bins and cars a large amount of the water drains off. The granulated slag is mixed with a slag cement in a proportion of one to eight, and the mixture is conveyed to an intermittent acting plunger press. The pressure is exerted from one side only and about 1000 bricks are made per hour. The bricks are sharp cornered and can be stacked without injury after leaving the press. Their hardening is affected by the atmosphere and after three or four months they are ready for use. They harden with age, as the chemical combination between the slag and the cement gets more complete, gaining also in compression strength, which already after a few months is about 1400 pounds per square inch. Slag bricks are in every respect as good as clay bricks. Their specific gravity is in the neighborhood of 2.6, i. e., about the same as an ordinary brick. They are grayish white, but by adding ochre or ultramarine to the mixture very nice color effects are created. As long as the bricks are not very hard, i. e., not very old, they can be cut and shaped quite easily for special purposes (profile bricks). As their resistance against high temperature is considerable, they are used in the construction of stacks and for boiler setting very extensively. They are not more hydroscopic than well burned clay bricks, but as they permit of a more thorough air circulation they are very valuable for the construction of hospitals and schools.

The total production of slag bricks cannot be ascertained; it must be very considerable, however, as nearly every modern European iron works manufacture slag bricks, and a single concern in Lothrinzen (Lorraine) turns out over 50,000,000 annually. In the granulating of slag it is advisable to have not less than 12 to 30 feet head of water, and the launder should have a pitch of 1 inch to the foot. It is a good practice to build the launder of slag bricks and cement, as every other material would wear too rapidly. For every ton of slag about two and one-half to four tons of granulating water are required, depending on the specific gravity of the slag, which varies from 2.5 to 3.5. In re-using the water a loss of 5% to 20% should be figured on.

In the manufacture of slag cement the granulated slag is disintegrated further by means of tube or ball mills, and the fine powder thus obtained is thoroughly mixed with slacked lime [$Ca(OH)_2$ Calcium hydroxide]. The slacked lime is prepared in the usual manner by adding to the burnt lime (quick lime) just sufficient amount of soft water to make it crumble into a fine white powder. The mixture of the disintegrated slag and the slacked lime powder must be thorough to give a good cement, and as it should be protected from access of the air to prevent the absorption of carbon dioxide, it has to be put into casks right away. The ratio between slag and lime powder varies according to the composition of the slag, and it must be established by careful experimenting. The qualities of a good slag cement are very similar to those of the best Portland cements or cements made by mixing slacked lime with Puzzolan or Santorin earth, Trass, etc. By adding 20% to 30% of water it hardens quickly to a stonelike mass, and after four to six months it is equal to the best of cements in strength. For hydraulic construction work it is not quite as good as Portland cement. A mixture of sand and broken stone makes a very good concrete. One cement plus 2 sand plus 4 stone equals 4.4 concrete, 1 plus 3 plus 6 equals 6.6 concrete, and 1 plus 4 plus 8 equals 8.8 concrete. The stone should not surpass 2½ to 3 inches ring size. The compression strength is sometimes as high as 500 kilograms per square centimeter, or about 7000 pounds per square inch, and the tensile strength is about 10% of this.

As slag bricks have a rather rough surface, the mortar adheres to them very readily and very little of it is required. Their manufacture is cheaper than the manufacture of ordinary bricks, as the expense of burning is avoided.

A composition of broken slag, slag sand and Portland cement is called metallic, and it forms a very good material for plastering streets, sidewalks, floors of factories, smelters and railway stations, in fact anywhere where the traffic is heavy. Steps and stairways are also made in this manner, and to give them a smooth surface only cement and slag sand should be used for the first few inches of depth. The usual volumetric proportion is two parts of slag and one slag-sand and one Portland cement mixed mechanically in a dry state. Water is added to make it plastic and then it is tamped in layers of 4 inches in thickness. An addition of soda speeds the hardening, and a street made in such a manner can be turned over to the traffic all ready after twenty-four hours. Sometimes single plates of 3 feet by 3 feet are made of metallic and joined by slag sand and Portland cement. In this case the ground underneath has to be very solidly tamped to prevent uneven settling and cracking.

The Reducing of Zinc Ores.

The production of zinc from its compounds involves difficulties due to the very electropositive nature of that metal, or, to put it into more modern terms, on account of the high value of the energy of combination of zinc compounds. In electrolysis this means the use of such high voltages, that other undesirable reactions take place for which that voltage is more than sufficient. In aqueous solutions, for instance, hydrogen is liberated much more easily than zinc. Such processes are, therefore, of special interest; all the more so as the electric methods have not yet come into use as much as might be expected.

In a recent article in the Electro-Chemical Journal, Danneel describes several zinc processes which were worked out at the metallurgical laboratory of the Institute of Technology of Aix-la-Chapelle. They chloridize the raw ore in the presence of salt solutions, such as sodium chloride and magnesium chloride, in revolving iron drums, lined with lead, at a temperature of 30° to 40° C., by means of free chlorine, obtained in another part of the process. The chlorides of lead, zinc and silver are then leached out with hot water or hot dilute lyes, obtained during the process. The following data of a test are given: 1000 kg. ore contained 140 kg. lead, 310 kg. zinc, 0.69 kg. silver. There were chlorinated and leached out 140 kg. lead, 175 kg. zinc, 0.11 kg. silver. In the residue there remained 135 kg. zinc, 0.53 kg. silver and 114 kg. sulphur. After the extraction of the sulphur, there remained a residue of 39.1% zinc and 0.168% silver. From the residue, the sulphur is removed by Schaffner's method under steam pressure.

The chloride lyes are purified by means of zinc oxide or roasted zinc ore, evaporated to dryness and dehydrated as completely as possible. The dehydrated mixture of chlorides is then electrolyzed in a fused state, and at the anode the chlorine gas is obtained which is used in another step of the process, as mentioned above; while at the cathode a mixture of molten lead and zinc is produced, which is obtained in two alloys—lead poor in zinc and zinc poor in lead. From the lead which is poor in zinc, the zinc can be removed by steam; the zinc which is poor in lead is refined by distillation.

The second process described was devised by Borchers and Von Kueglegen, and is for treating waste from zinc galvanizers. This waste is dissolved in hydrochloric acid to saturation. The iron is removed from the solution by means of chloride of lime and other oxidizing agents; it is then evaporated to dryness in iron crucibles lined with lead. The pulverized zinc chloride is mixed with metallic oxides—for instance, copper oxide and calcium carbide—and is then melted to zinc alloys—brass. The reaction between zinc chloride, metallic oxide and calcium carbide goes on by itself, owing to its own heat of reaction, after the reaction has been started

by means of an incandescent body; but to obtain good metal it is necessary to heat the crucible.

The third process described was devised by Dorsemagen, for the treatment of siliceous zinc ore, especially if the percentage of zinc is small; zinc and silicon carbide (carborundum) are produced. An electric furnace is used. A mixture of carbon and siliceous zinc ore is heated in the furnace by a carbon rod; the zinc is distilled off, and there remains silicon carbide. The reduction temperature of the silica is only slightly above the distillation temperature of zinc.

The fourth process described is by Borchers and Dorsemagen, and is analogous to the last described. It is used for the treatment of ores containing iron and zinc, in order to get ferrosilicon and iron. The process differs from the last one only in so far as ferrosilicon, instead of silicon carbide, is obtained.

The Dewey Mine.

The accompanying illustrations are of the Dewey mill and open cut on the vein. The mine is in Siskiyou county, Cal., near Gazelle. The mine is extensively developed by tunnels, several levels having been opened. The ore is largely mispickel, containing gold. The vein is said to carry about $9 per ton, beside which there is a large amount of ore of lower grade. The mill contains ten stamps, two Frue vanners, two Wilfley tables and hydraulic classifier. There is also a canvas plant and cyanide works. The premises are lighted by electricity. There is an air compressing plant and machine drills are used in the mine. Water power is said to be available to run the entire plant. The Dewey mine is one of the important mines of Siskiyou county.

Open Cut, Dewey Mine, Siskiyou County, Cal.

Dewey Mill, Siskiyou County, Cal.

Hematite in Spain.

According to a recent report, says the London Mining Journal, within the last year a rich vein of oxide of iron ore has been discovered near the city of Jaen, in the province of that name, about 85 miles from Malaga. The Compania Mineralurgica, the firm owning and operating the mine, has estahlished a plant on the outskirts of this city, where the ore is refined and prepared for export.

The owners claim that this deposit is the only one of consequence in Spain, a small mine near Santander being its sole rival. The ore is known as hematite, or sesquioxide, and those interested claim that it possesses a durability of color and the other properties necessary for the manufacture of red paint not excelled by any other mine in the world.

The ore is shipped both in its crude state and refined ready for mixing with oil. Levigation is effected by submitting the crude ore to the process of grinding by stone crushers. It is then forced through filters of purified water and finally dried in kilns. The result is a fine red powder, which mixed with a trifle more than 10% of linseed oil, produces paint ready for use. Iron structural work of all kinds is usually protected by a coating of this paint. The Malaga product was invoiced at 50 pesetas per short ton of crude, and at exactly double that price for the levigated or prepared material. At present, however, the ore finds its largest market in England.

Ajax Drill Sharpener.

The Ajax drill sharpener shown in the accompanying cut is a power machine for fashioning and resharpening machine drills. To sharpen drills by this means it is necessary that the drills be placed in a coke forge of large capacity (the common forge will not heat drills fast enough for this machine), and when it is at the right heat it is placed under the upright hammer, which sidesets and pinches out the edges to a sharp cutting edge. The drill is then placed in the dies in the upsetting machine, the dies are closed on the bit and the dollie, which is held in the chuck, is allowed to strike the bit until it has been upset enough, when the tailblock which holds the drill to the dollie is allowed to run back, when the dollie will drive the bit into the die, which finishes the bit to the exact size of the die. These dies are made in the different sizes required. The advantage of having drills made in a die can be readily seen, for they are then all correctly gauged, for example: Say that the die for a starter bit is 2½ inches wide, every drill that is made in this die will be 2½ inches wide when it is finished, and so it is with every other size, the dies control the gauge.

The manufacturers of the Ajax drill sharpener claim that, even though the mine has only 100 drills to sharpen each day, this machine will pay for itself in the time saved and the saving in wear and abuse that the machines get under ground from inaccurate drill sharpening. It is as easy, they say, for a crew of sharpeners to sharpen 600 drills each shift with this machine as it is for them to sharpen 125 by hand. In one instance the saving in the shop alone amounted to 75% over handwork, to say nothing of the saving underground.

The peculiar feature in the making of these machines, they say, is that no two mines use the same system for making drills, and it is, therefore, necessary that the manufacturer knows every detail of the system at each mine. To illustrate, at the Homestake mines a starter bit is 2¾ inches wide, at the Alaska-Treadwell mine it is 2½ inches wide, at the Jumper mine in California it is 3 inches wide, at the Tamarack and Kearsarge mines in Michigan it is 2¼ inches wide, and so on. It is different at each mine, and of the twenty of these machines now running no two have dies just alike. In order to make these machines standard it would be necessary that almost every mine would have to change their entire lot of drills, which, it is claimed, would cost more than this machine. Then again, some mines have hard rock which requires one kind of a bit, and others have soft rock which again requires another kind of a bit; some mines have both hard and soft rock, so require dies for the different kinds of rock. This machine is sold by Harron, Rickard & McCone, 21-23 Fremont street, San Francisco, Cal.

Ajax Drill Sharpener.

The Del Prat Process.

It is expected that some time will elapse before the working tests of the Del Prat salt-cake process of sulphide treatment, which are being carried out at the Broken Hill Proprietary mine, are completed. The Australasian states that the cost of the chemicals used in the process for the crux of the position has yet to be determined. The plant used in the tests will cope with at least one ton of material per hour. Six of the pans could treat about 1000 tons weekly. The cost of the plant must be moderate compared with the machinery necessary for other processes at work on the field in connection with the zinc problem. Briefly described, it consists of a copper pan, 6 feet long by 3 feet wide, with sloping bottom, below which a number of gas jets are placed. At the end are the settling pits for the product, and below the pan is a boat or small bin, into which the accumulated waste falls. Under this again is a larger bin. There are two tanks, a primary mixing tank, in which the saltcake is dissolved, and another elevated lead-lined tank for the solution in active use. The liquor which carries the concentrates to the settling bins flows by means of launders to settling tanks below the trucking floors, from which a steam pump raises it to the initial storage tank. The plan is simple in its working, and evidently does not require very delicate handling to secure good results.

[Crude sodium sulphate is known as salt cake, andis utilized to make a liquid of high specific gravity. In this the pulverized mineral falls, the zinc blende ascending to the surface, where it overflows into a tank, the gangue and other sulphides being recovered later from the separating tank.—Ed.]

The crucible process of making fine steel, says Sparks From the Anvil, will probably never be superseded by other methods. Selected irons with their "medicines" are melted in crucibles which are luted and sealed, where chemical reactions take place unseen and unaffected by outside influences. For securing high quality, accuracy of what the steel maker calls "temper," there is no substitute process in sight. When steel has been overheated the property called temper is destroyed. This may in a measure be recovered by careful manipulation.

The Cost of Gold Milling.

The difficulties in the way of comparison of the total cost of extraction in various gold fields of the world, says S. Horsley in the Queensland Government Mining Journal, are:

First. The nature of the power used—e. g., water power is much cheaper than the most effectively applied steam power. If steam power is used, the relative cost of fuel must be taken into consideration. Extraction is much less costly where coal is obtained easily and cheaply than where indifferent firewood costs 30s. per cord.

Second. The nature of the material to he crushed. Hard material is not so easily crushed as a soft or friahle material. A custom battery putting through 4 tons per stamp per day for one mine finds itself unahle to put through more than 2 tons per stamp for another mine. Here the nature of the material causes one mine to pay twice as much for crushing as another mine.

Third. The numher of operations or processes necessary for a complete extraction.

Where coarse gold only occurs in an easily pounded quartz in close proximity to ample water power the cheapest conditions possible for almost complete extraction are realized. But the case is exactly reversed where gold occurs in minute particles locked up in or combined with other suhstances which are hard and resisting, and which occur in waterless areas, where inferior fuel costs 30s. per cord.

Under favorahle conditions, such as the occurrence of large deposits, requiring an extensive milling plant, the total cost of extraction might he as low as 9d. per ton in the former case. Yet the most efficient machinery comhined with the most approved methods of treatment have failed to hring down the total cost of extraction so low as 10s. per ton, or thirteen times as much as in the latter case.

The way out of the difficulty is now apparent. Since the total cost of extraction necessarily varies so largely, we are unahle to derive any useful information from a comparison. A great deal can he learned, however, if, after the hardness of the material has heen defined according to some prearranged standard, the cost of fuel per indicated horse power per ton and the cost of each separate operation or process is separately recorded.

It is also natural to expect a hattery of 100 heads to crush more cheaply than one of 10 heads. But a company which finds 10 heads a sufficient numher to erect on their mine cannot he said to lack economy. Although an examination of the cost of extraction hy the various gold milling plants of the world reveals a wide divergence, yet the divergence is not so marked when the cost of each separate process is considered.

At Chiapas, Mexico, the cost of milling the soft ore there is only 9¾d. per ton of 200 pounds, with a 10-head battery having 750-pound stamps. The cost of the power is not taken into account, as water power is used. The Alaska-Treadwell Co., Douglas Island, Alaska. with 540 stamps, crushed and concentrated for 9¾d. per ton in 1900. This company's costs for total extraction—milling, concentration, chlorination, smelting and office expenses—were:

Year Ending—	Quantity Treated. Tons.	Value per Ton. s.	d.	Total Cost Extract'n. s.	d.
May 31, 1899	250,408	10	10	2	1
May 31, 1900	557,960	8	4	1	6¾
May 31, 1901	457,802	8	3	1	5½

Their total costs for mining and milling for the same periods were 5s 1½d., 3s. 7¼d. and 4s. 4d. per ton, respectively.

The Alaska-Mexican Co., at the same place, with 120 stamps, crushed and concentrated for 1s. 2d. per ton in 1899. They put through during 1899 166,054 tons, valued at 8s. 7½d. per ton, for a total cost for mining and milling of 7s. 1d. per ton. The total extraction costs were 1s. 11½d. per ton of 2000 pounds.

The Homestake Co., S. D., crushed nearly 900,000 tons for the year ending June 30, 1900. The total milling costs were 3s. 4d. per ton and the total mining costs 10s. 9d. per ton, a grand total of 14s. 1d. per ton. For the year ending June 30, 1901, the Homestake Co. mined and milled 934,373 tons, valued at ahout 16s. per ton, for a total cost of 14s. 8d. per ton, thus making a profit of nearly £63,000 out of ore of a quality that is practically despised in Queensland. There are large deposits of low-grade ore, similar in character and value to that mined hy the Homestake Co., and superior to that mined hy the Alaska companies, in parts of Queensland as yet harely touched hy the miner.

The milling costs of the De Lamar M. Co., Idaho, for the year ending March 31, 1899, were 9s. 3¾d. per short ton.

The total cost of mining and milling at the following mines for the period ending with the date given is as follows:

Year Ending—	s.	d.
Dec. 31, 1901—Montana G. M. Co., Mont.	36	10½
June 6, 1899—Montana G. M. Co., Mont.	23	6¾
1899—Mill at Bend'Or, B. C.	21	4
Aug. 8, 1901—Morro Velho Mines, Brazil	25	8
Dec. 31, 1899—New Elkhorn M. Co, Mont.	66	10

The milling costs—or total cost of extraction—of the last-named company at the date given was 39s. 7d. per short ton.

There is thus a wide difference hetween the 9¾d. per ton of the Alaska-Treadwell Co. and the 39s. 7d. per ton of the New Elkhorn G. M. Co.

In Western Australia the Lake View Consols crushed and cyanided for 10s. 1½d. per ton in 1898, and for 6s. 10½d. per ton in 1899, hut the extraction was unsatisfactory when sulphides came to he dealt with. For these other methods were adopted, and on August 31, 1900, the cost of extraction was 43s. 5d. per ton. This amount was reduced to 32s. 10d. per ton during the last three months of 1900, and was still further reduced in 1901 to 28s. 3d. hy the adoption of the Diehl process.

At the Great Boulder Perseverance mine the costs of extraction were 34s. 11½d. in 1900, and 24s. 10½d. per ton in 1901.

At the Ivanhoe mine, Kalgoorlie, during November, 1902, the reduction costs were set down at 10s. 4d. per ton; mining, 14s. 3d.; general, 3s. 5d.; development and capital, 6s. 2d.; total 34s. 2d. per ton. The question here is, what part of the general expenses is connected with the process of extraction?

At the Kalgurli mine, for the same period, the total mining and crushing costs were 38s. 5d. per ton—presumahly a short ton in all Western Australia instances.

At Mount Morgan, Queensland, the cost of dry crushing for 1900 is given as slightly under 4s. per ton.

At the New Ravenswood, Ltd., Ravenswood, the total cost of mining and milling their refractory ore is (1902) 38s. 10d. per ton—2240 pounds. The works here, however, are not yet complete.

The Brothers' mill, Ravenswood, cart and crush hard mineralized quartz for 15s. per ton, and dyke stuff for 8s. 3d. per ton, Carting in the former case costs 1s. 6d. and in the latter 9d. per ton. Concentration hy Wilfley tables is included, hut not cyanide.

The Commonwealth mill at Donnyhrook for similar treatment charges 16s. per ton, viz., 2 for carting and 14s. for crushing, etc.

The cost of crushing, concentration, grinding and smelting of concentrates at the Imperial mine, Charters Towers, for the half year ending Novemher, 1901, was 9s. 8½d. per ton of 2240 pounds. Their total mine, hattery and office costs were 28s. 4¾d. per ton.

The usual charges for carting and crushing at the Charters Towers mills are as follows:

	Per Ton. £	s.	d.
5 tons or under	5	00	0
Over 5 tons and up to 25 tons	0	14	6
Over 25 tons and up to 50 tons	0	13	6
Over 50 tons and up to 100 tons	0	13	0
Over 100 tons	0	12	6

Carting costs variously up to 2s. 3d. per ton, all of 2240 pounds. These prices, though apparently high, leave a very small margin of profit. Numerous small crushings for the public cause much loss of time and require a large numher of pits for saving the tailings, also entail considerahle extra cost of cleaning up. If a mine, owning its mill, could keep it fully supplied, the crushing, concentrating and grinding costs would prohahly not exceed 7s. 6d. per ton.

The cost of crushing and concentration only at some of the mills is stated to he not much over 3s. per ton. Grinding and the drying and hagging of concentrates necessitates this amount, and further expense is entailed by cyanide treatment or smelting.

The exact cost per ton at Charters Towers of a 5-ton lot or a 1000-ton lot does not appear to he known, and in high-grade districts like Charters Towers and Ravenswood there will always he numerous small lots raised, and there must he custom hatteries to treat them.

As regards the duty per stamp per twenty-four hours in various parts of the world, nothing can he done in the way of a correct comparison unless the hardness, etc., of the material to he crushed is first compared with some standard. Even within the limits of Charters Towers and Millchester variations in the hardness of the material affect the rate at which it can he crushed. At Ravenswood one party of trihuters has to pay the mill owner nearly twice as much as another party has to pay owing to the difference in the character of the material crushed. It may he said that the hest mills at Charters Towers and Ravenswood crush rather over 2 tons per stamp per twenty-four hours of very hard mineralized quartz, and they will crush 4 tons per head per day of softer stuff, and each ton of 2240 pounds—not 2000 pounds.

Most of the mills at Charters Towers have high pressure steam, compound condensing engines, rock breakers, self-feeders, etc., and are not hehind hand in adopting the latest gold or mineral-saving device if it suits the ore which occurs in the gold field.

COMPARATIVE TABLE OF GOLD MINING AND MILLING COSTS.

Year Ending	Name of Mine or Mill.	Annual Tonnage (2000 Pounds)	COST PER TON OF ORE. Power	Crushing and Concentrating	Cyaniding or Chlorination	Smelting	Administration	Total Extraction cost	Total Mining Cost	Grand Total	Average Stamp Duty per ton 24 Hours

Assaying Cyanide Solutions.

To the Editor:—In your issue of June 6, W. H. Davis of the Idaho Gold Coin M. & M. Co., Bear, Idaho, comments upon "Assaying Cyanide Solutions" hy a method mentioned hy A. H. Jones of the Smuggler-Union, Telluride, Colo.

Have used practically the same method as Mr. Jones, hoth in this country and in South Africa, hut have never experienced the discrepancy mentioned when the other part of the work was looked after with the same care as the assaying of the solution.

Have checked up the clean-ups extremely close with this method on low-value solutions where the lead-tray method gave varying results.

Can see no reason why there should he any more loss due "to the infusihility of zinc silicate or loss hy suhlimation with zinc during the assay" than there is in the assay of zinc ores. The assay of this precipitate gives a heautifully fluid slag.

There might he a loss due to incomplete precipitation, as Mr. Davis suggests, or it might he a mechanical loss due to incomplete filtration. This, it would seem, is ohviated hy the method I have used, which differs from that of Mr. Jones in this particular: The litharge used for assaying is added before filteriug; also, some milk of lime and soap solution are afterwards added. These, mechanically, take everything out of solution, clarifying it and leaving a precipitate that readily filters. The solution will run through the filter ahout as fast as it can he poured on. The assay, then, is finished, as Mr. Jones states.

Maiden, Mont., June 10. C. T. Durell.

Mining Summary.

Specially compiled and reported for the MINING AND SCIENTIFIC PRESS.

ALASKA.

Alaska-Treadwell G. M. Co. at Douglas May returns show the 240-stamp mill ran 29½ days and the 300-stamp mill 23½ days, crushing a total of 72 889 tons of ore, for bullion valued at $68 974, and 1640 tons sulphurets, valued at $90 476. Working expenses for month, $53 313.

F. M. Stone, manager of the Alaska Treasurer Co., reports he will start further development work on the group on the lower end of Douglas Island.

Placer mines on Slate and Silver creeks, Windham Bay district, are reported running 10 cents to 15 cents per pan. Several quartz properties are being worked.——The Yellow Jacket Co. is putting in machinery and expect to increase development.——The Jennie Reid G. M. Co. report work progressing.

At the Alaska-Juneau mine, in Silver Bow Basin, near Juneau, forty-five stamps are dropping. Three machines on day and two on night shift are breaking ore. The company has fifty men at work.

Near Ketchikan, preliminary work on building a smelter has been started by the Brown-Alaska Co., says Manager P. Johnson.

The Crystal G. M. Co. is dropping five stamps at its mine in Snettisham district, says Manager B. Hines. The ore bins are filled with milling ore.

Manager P. Early of the Bessie G. M. Co., operating at Yankee Cove, reports the foundation down for the 2 mile wagon road and the sawmill cutting lumber for the planking. The stamp mill machinery is being taken in.

O. E. Sauter, speaking of oil in Alaska, tells the Alaska Dispatch one of the oil fields extends northwest from Yakatago to Valdes, a distance of 125 miles, and the other extends from Valdes southwesterly along the Alaskan peninsula to Chigik bay, a distance of 150 miles. There are oil indications in all of this district. At Catalle there is one well producing, and at Iliamna there are several wells down. Two rigs have been started at work at Cold bay, one by A. Castella of Buffalo, N. Y., and the other by J. Cary of Washington.

The Oil Reporter says it is estimated that 1000 men are in the Alaska oil fields, and that during the summer 5000 are expected to be on the ground.

ARIZONA.

COCHISE COUNTY.

A 10-stamp mill will be built by the Golden Era M. Co., near Bisbee, and the plant is expected to be in operation by Aug. 10.

The Duluth & Pittsburg Dev. Co. has been incorporated at Calumet, Mich., to operate near Bisbee. The directors are C. Briggs, P. Rappe, J. S. Dymock, C. A. Conger, G. E. Tener, C. d'Autremont, J. Hoatson, T. F. Cole and T. Hoatson. The company has a shaft down 200 feet and development work will be continued.

At the Twilight mine, near Bisbee, the machinery has been placed in position, says Superintendent Parnell, and when the hoist is in position the shaft will continue sinking. Compressed air drills will be used.

E. C. Bartlett of Dillon, Mont., has bought the Rider group of copper claims near the Burns group, owned by the Chiricahua Dev. Co., in the Chiricahua mountains, near Douglas, and will begin work this month. One claim of the group has a showing of copper ore at depth of 80 feet in a shaft, the bottom of which is all in ore assaying 16% copper and with some silver and gold, says the Douglas International.

Development on the Amole No. 1 of the Martinez G. M. Co. group, in Yellowstone district, north of Benson, is confined to a tunnel being driven to cut the ledge at depth of 250 feet. The tunnel is in 170 feet, and expected to cut the vein at 230 feet. The open cut above the tunnel has shown the vein to be 2 feet in width, with values running $80 per ton. Work on shaft No. 8 is down 40 feet and shows a ledge of 2 feet of free milling ore.

MARICOPA COUNTY.

The Arizona M. & Dev. Co. are operating the Ryland lead and silver mine, near Wickenburg.

It is reported the 10-stamp mill on the O'Brien mine, near Wickenburg, will be enlarged by addition of twenty stamps. A hoisting plant will also be put in.

At Wickenburg, T. Elder, W. S. Rees & Co. expect to blow in their 30-ton water-jacket smelting furnace next week.

MOHAVE COUNTY.

(Special Correspondence).—The Tennessee mine at Chloride is in silver-lead ore of good grade in the drift on the 600 level. The Elkhart mine and mill are both in operation. The mill is handling 100 tons daily. The Minnesota mine and mill have been idle of late, but W. J. Cleeland, president of the Philadelphia & Arizona M. Co., is expected from Philadelphia, when it is expected work will be resumed. Ore in some parts of the mine is looking well, the vein is of good size, and carries forty ounces silver. The Samoa mine, operated by Hoffman Bros., continues in rich shipping ore. Some of this ore carries 2000 ounces silver to the ton, one and one-half ounce gold and 1% to 8% copper. The principal work is on the 350 level. The Lucky Boy mine, adjoining the Samoa on the north, belonging to T. B. Scott and others of Chicago, Ill., is working twenty-five men. Ore from this mine is being packed to the railroad by jack train and shipped. During June four carloads were sent out. It is locally reported that work on the Pinkham mine is to be resumed. The mine is owned by the Schee Bros. of Santa Monica, Cal., who have developed it while extracting a large quantity of low-grade ore. The mine is thoroughly equipped. J. Barry has let a contract for the sinking of the 140-foot shaft on the Sunrise mine 100 feet deeper, and the steam hoist has been overhauled. The Sunrise ore is low grade. The shaft so far, in sinking, is all in ore. The Payroll mine will be worked again, say J. M. Murphy and I. M. Hawkins of Kingman, owners. The work to be done will consist mainly in developing the lesse formerly opened up, also in sinking of the shaft deeper and driving a crosscut for a parallel vein, which shows good surface croppings. The mine has an abundance of water. The silver discovery by J. Carroll, near the Juno mine, is being developed, the vein of ore showing 2 feet wide, and assaying fifty ounces silver.

Chloride.

YAVAPAI COUNTY.

The B. B. mine in Cherry Creek district, near Cherry, 15 miles south of the United States group, which has been shut down for four years, will be reopened, says Manager De Keuhn.

CALIFORNIA.

AMADOR COUNTY.

At the Gover mine, near Amador City, the framework on the mill is finished and the machinery is being put in.

CALAVERAS COUNTY.

The Dunharton Castle mine and the Homestake mining claims, near Railroad Flat, have been bonded to L. M. Rucker of San Jose, who will begin operations next week. He will drive a tunnel into the hill and expects to strike the vein at depth of 500 feet.

The 120-stamp mill of the Royal Con. M. & M. Co. at Hodson is expected to start up next week, says the Citizen.

Last week at the Purinton gravel mine, 4 miles from Angels, the 1100 foot tunnel was finished. The tunnel tapped the channel near the old workings, in which a great deal of water had collected. No more work will be done until after the channel is drained, says Superintendent F. Purinton.

EL DORADO COUNTY.

The Bryan roller mill at the Game Cock mine, Webber Creek district, near Placerville, was started up last week. Work continues at the Mammoth mine across Webber creek from the Game Cock, the tunnel being in 291 feet. They have a 16 foot ledge; both properties are being developed by the Rustler M. Co.

The El Dorado G. & C. M. Co. has made final payment of $10,000 on the Eureka and Woodside quartz mines, near Georgetown. The company has also bought the Modoc, the Van and the Bilger quartz mines adjoining the Whiteside and the Eureka. A steam hoisting plant will be built. In addition to the gold quartz mines the company owns the Ford copper mine on which development work continues.

The 10-stamp mill at the Jasper mine on Webber creek, near Placerville, is in operation, and in the mine they are drifting on the 100-foot level.

FRESNO COUNTY.

At Coalinga, H. H. Brix, manager of the Coalinga Con. Water Co., has taken an option on the Barker section of oil land.——Additional ground has been bought by the Rhode Island-California Oil Co. and work will be begun this month.

KERN COUNTY.

The Southern Pacific R. R. Co. is reported to have bought forty acres additional of oil lands at McKittrick from the Alta Oil Co. for $2000 per acre. There is one producing well finished on the land and the railroad is expected to drill another, starting operations this month.

The Metropolitan Co. has incorporated at Bakersfield, to operate in oil and mines, with principal office at San Francisco; F. C. Drew and H. Bernard of Alameda, C. B. Gillespie, F. Hall and J. G. Weir of San Francisco.

NEVADA COUNTY.

Electric machinery for the Brunswick mine, near Grass Valley, is on the ground. The insulated electric cable for the main shaft is 1250 feet in length and weighs 1430 pounds. The three electric pumps have a capacity of 1200 gallons per minute. The work on the 16x16 duplex compressor is finished.

The Grass Valley Con. mine at Grass Valley has been sold to J. M. O'Brien of San Francisco. G. W. Root is manager of the company which has been working the mine under bond. He says development will be increased.

The Centennial mine on Osborn hill at Grass Valley is reported sold to G. W. Root, manager of the Grass Valley Con. M. Co. In addition, Manager Root also bought for his company the Dewey, Electrum and Pinnacle mines.

The Zeibright M. Co. has been incorporated at Nevada City to operate the Zeibright mine south of Grass Valley and near the Placer county line. F. Zeitler, W. F. Englebright, J. J. Jackson, F. Searls and J. Spaulding are directors. Work is in progress at the mine putting up buildings and an air compressor and the tunnel will be driven ahead.

The Potosi Orleans M. Co., operating the Federal Loan mine in Willow valley, near Nevada City, have put in three more machine drills. As soon as repairs are made the 10-stamp mill will be started.

PLACER COUNTY.

The Chicago mine, near Penryn, is being reopened by H. B. Hilgeman of St. Louis, Mo., with J. M. E. Manley of Penryn as superintendent.

The Hidden Treasure M. Co., operating the Hidden Treasure drift mine at Centerville, has 20 men at work.

PLUMAS COUNTY.

H. Gobert, part owner of the Crown Point mine on Squirrel creek, 12 miles from Quincy, reports their 10-stamp mill, on a ten days' run on seventy-five tons of ore, working nine hours a day, produced ninety-eight and three-fourths ounces of gold, valued at $2000.

Operations were begun at the Claybank tunnel, near Laporte, last week, says Superintendent D. Corbett. Two shifts are driving to tap the channel.

SAN MATEO COUNTY.

At Half Moon Bay, at 1520 feet, the Paxton Oil Co. report striking stratum carrying 50° gravity oil of a light color.

SANTA BARBARA COUNTY.

An oil well has been brought in near Careaga Rancho, in the northern part of the county, the first flow being at the rate of thirty barrels per minute, say the reports. Oil shut 50 feet above the top of the derrick. The depth of the well is 2000 feet.

SANTA CRUZ COUNTY.

(Special Correspondence)—J. Enright is operating the Stribling mine, about 5 miles northwest of Santa Cruz. The mine until recently had been idle for many years, though at one time equipped with a mill. The formation is granite and a vein of quartz reported to have been rich was discovered and worked to shallow depth when the vein pinching work was discontinued. Mr. Enright is doing development in search of new ore bodies.

Santa Cruz, June 30.

SHASTA COUNTY.

At the Conner gold mine on Salt creek, near Redding, a shoot has been opened up in the main vein. The streak was struck in the drift being run from the hanging wall of the main vein and 100 feet from the mouth of the drift. The tunnel being run on the hanging wall of the main ore body will be driven ahead 800 feet, cutting a series of veins. The last or most westerly will be cut at depth of 500 feet from the surface.

The work of rebuilding the dredger of the Detroit-California Dredging Co., destroyed by fire, on Clear creek, near Horsetown, near Redding, has started this week, says President Heintz. The total loss was $80,000 and $30,000 insurance was held.

SIERRA COUNTY.

Operations have been resumed at the Kenton mine, at Alleghany, says Superintendent A. Fitzgerald.

The Wild Boar mine at Gibsonville is putting in machinery, including an electric plant, to furnish power to sink the incline to show the depth of the channel struck last month.

SISKIYOU COUNTY.

At the Blue Ledge group of copper mines on Joe creek, near the Oregon line and near Jacksonville, Or., Superintendent J. P. Harvey says a smelter will be built. The group is owned by P. Clark and M. Kingsbury of Spokane, Wash.

Hadley & Co., who have a bond on the Parks placer ground at Yreka, have placed a pump with engine and boiler for drainage of same while sinking shaft and hoisting pay gravel from bedrock.

TRINITY COUNTY.

At the Three Peaks mine, on Battle creek, in Coffee Creek district, near Carrville, owned by the Three Peaks M. Co., operations have been resumed, the snow having melted sufficiently. G. Hurst of Redding, superintendent, is putting in additional machinery, and the mill is expected to be ready for the stamps to drop next week.

TUOLUMNE COUNTY.

(Special Correspondence)—The old Golden City mine, near La Grange, is in operation after an idleness of many years. Naylor Williams is opening the mine under bond and is prospecting for new ore bodies by means of crosscuts, and is reported to have made important discoveries.

La Grange, June 29.

Superintendent W. P. Miller, at the Keltz mine, near Columbia, has sixteen men at work and five stamps are dropping in the mill. Prospecting is being done farther to the north along the line of the lead.

More men have been put on at the Mazeppa mine, near Stent, making twenty men at work. The 10-stamp mill is running steadily.

Development work is progressing at the Shoenberg mine, near Groveland, says Superintendent Dale. A crosscut at depth of 80 feet shows the vein to be 7 feet between walls. Drifting is being done east and west on the vein. It is proposed to put in a hoist and continue explorations to greater depth.

YUBA COUNTY.

Machinery is on the ground for the gold dredgers building at Camptonville. They will operate along the North Yuba river, handling the sands and gravel as well as the tailings from the hydraulic mines. The prospecting drills have shown pay dirt on the bottoms of the old channels.

COLORADO.

BOULDER COUNTY.

The Montgomery M. & M. Co. of Colorado Springs, owning fifteen acres of land at Ward, has decided to build a cyanide mill to handle the tailings from its 10-stamp mill. The mill is handling thirty tons a day, concentrating twelve into one. Tables are used. The company has developed the mine to depth of 240 feet by two shafts and two tunnels. The ore is free milling. R. Mullen of Colorado Springs is president.

CUSTER COUNTY.

Lessee Murphy of the Vanderbilt mine, near Custer, is putting in machinery. In one of the open cuts has been started a shaft that will tap the ore body.

CHAFFEE COUNTY.

The Independence mine at Turret will have a 50 ton leaching plant, work on which has started. It is expected to be ready by August 1. The principal values are in copper.

FREMONT COUNTY.

The Keystone Oil Co. near Florence struck oil at depth of 1700 feet in well No. 6 last week. This oil body will produce twenty barrels per day, but as a larger supply exists 1000 feet lower, the hole will be deepened.

The Portland Cement Co. has men at work in its gypsum deposits at Coaldale, which have been opened up so that fifteen carloads are daily sent to the cement factory, 6 miles east of Florence.

GILPIN COUNTY.

C. S. Palmer of Kansas City, Mo., owning the Sarah Jane mine, in Pine mining district, near Central City, says the Sarah Jane has been consolidated with the Mackey group, owned by L. J. Mountz. Arrangements have been made to build a mill of thirty tons daily capacity at the junction of Elk and Pine creeks.

Omaha, Neb., men, interested in the Electric Spark G. M. Co., have taken the Shamrock group, near Russell Gulch, under lease and bond and have put up a shaft building and a steam plant of machinery. The main shaft is 350 feet deep and is being retimbered. J. C. Martin is manager.

The Blue Grass M. Co., near Central City, will build a stamp mill this summer, says R. L. Parish of Leon, Iowa, president and manager of the company. It will be a 10-stamp rapid-drop mill with 800-pound stamps, and will use table concentrators. It will be on the millsite owned by the company on Beaver creek, and 1700 feet distance from the mines. Water is coming in at the Lone Star mine and the 200 gallon water skip in order to handle 30,000 gallons each day has to be used steadily for six hours. The company will put in a pump.

T. K. Brooks has a lease and bond on

the German and Phœnix claims in Phœnix district, near Central City, and is arranging to put up a hoisting plant on the German.

W. H. Myers & Co. have a lease and bond ou tbe Gold Anchor mine midway between Perigo and Wide Awake. There is a tunnel in 300 feet which will be retimbered and 600 feet of track put in.

The Edna G. M. Co. has its concentrating plant, below the junction of Russell and Lake creeks, near Russell gulch, in operation. Water for the plant is pumped out of the Edna tunnel. The ore is coming from the Mida G. M. Co.'s ground, operated by the same parties, with E. C. Miles superintendent of both mines and the plant.

GUNNISON COUNTY.

Operations on the Hercules and Ajax lodes at Elko are under way. Development work so far shows a vein 4 feet in width and assaying $2 in gold, 26 ounces in silver and 4% copper.—The Elk Basin M. Co. reports work progressing on its group of claims in Elk Basin, near Irwin.—The North Pole M. Co. continues development on its group in Crystal district, near Elko. Copper ore is showing.

The Mono mine, near Pitkin, is in operation by J. M. Gardner & Co., who hold a lease from the Mono M. Co. They have low-grade ore contracted for from several properties, also there is an ore body showing in the Mono tunnel, which will be treated at the mill. The Mono tunnel is in 500 feet. — Ore is being taken out of the Jessie and Hill Top mines by T. Stanley for treatment at the Mono mill. There are 2½ feet of mineral showing that runs $16 per ton in gold. The pay streak in the Hill Top is a foot in width and runs $25 per ton. — The Whig Co. continues development work. Its shaft has passed through a stratum between the oxide and sulphide zones.

At Vulcan, the Dubois Tunnel Co. last week crosscut the Pride of Denver vein for 50 feet, and at a depth of 450 feet, says W. S. Chenoweth, of Davenport, Iowa, manager. Chenoweth is also interested in the Davenport and Adair group in the same district, on which two tunnels are being driven to cut a series of veins. When these veins are developed sufficiently to warrant a heavy output, a concentrating plant will be built.—The Headlight M. Co. is sinking its shaft near Spencer, which is down 180 feet, and it will be continued to 200 feet before the first level is run on the vein. The vein has been followed from tbe surface, and carries values in gold, says Superintendent Ehlerding. — Progress is being made in sinking the Good Hope shaft. It is down 500 feet, and will be continued farther before the level is run into the ore shoot.

HINSDALE COUNTY.

(Special Correspondence). — For some time the large mines around Lake City have been contemplating tbe erection of a smelter to handle their ore. D. A. Farrell, manager of the Red Rover mine, is at the head of the project. The smelter will be built during the summer at Gunnison.

Lake City, June 29.

JEFFERSON COUNTY.

The Clear Creek M. & R. Co. reopened its smelter at Golden last week after a shut down of three months, on account of repairs and difficulty with the union. By a compromise the labor trouble has been settled. The company intends to build a refinery.

LAKE COUNTY.

Leadville advices estimate the output of the camp for the month of June at an average of 2800 tons a day, and in July this is expected to be increased to 3000 tons. The most of this will come from the Coronado and the Ibex mines, as the shaft of the latter company is being connected with the Yak tunnel. Tbe Western M. Co. is shipping 500 tons daily, and next week this will be increased to 650 tons. Tbe ore is coming from the Wolftone, Midas, A. Y. and Minnie. The pumps at the Wolftone are raising 1000 gallons of water per minute.

The Leadville-Oro M. & L. Co. will begin operations next week to develop the ground between the Carbonate fault and the Bon Air and P. O. S. mines at Leadville. This includes tbe Oro and the O'Donovan Rossa claims. It is intended to sink a shaft to depth of 600 feet and drive a drift northwest from that depth to cut the ore shoots developed by the Bon Air and P. O. S. Machinery will be placed, and tbe work of excavation for foundation for boilers and engine is under way. A shaft, 3½x7 feet, is already sunk to depth of 320 feet. This will be enlarged and sunk to tbe proposed depth. The company is composed of Texas and Denver men, with W. G. Nicholson of Denver as president and J. R. Curley as manager.

LA PLATA COUNTY.

The Tenbroeck, near La Plata, has been leased to L C. Williams, who will drive a tunnel 200 feet under Lewis mountain, obtaining a depth from surface of 1000 feet. — The Bay City mine, under lease to G. Dotson, has begun shipping ore to Durango. The mine is within 200 feet of the wagon road and 7 miles from Hesperus station on the Rio Grande Southern. It also has milling ore. — The Bonnie Girl Co., operating near La Plata, are increasing development work, says Manager McLeod. They will remodel the stamp mill to include cyaniding.

MINERAL COUNTY.

Manager J. Nause of the Nelson Mountain M. Co. bas work under way on their group of claims on Nelson mountain, near Creede, which they are operating under bond and lease.

SAN MIGUEL COUNTY.

The Keystone Hydraulic M. Co., operating the Keystone placer on San Miguel river, 5 miles below Telluride, began washing gravel last week. C. M. Coleman is manager. The gravel at the bottom of the pit at bedrock, where the washing is going on, carries 50 cents per cubic yard, and 25 cents near the surface.

The Tom Boy G. M. Co., near Telluride, has put three of the seven Huntington mills in the old plant, which has been idle since December, 1902, by reason of the lack of water for milling purposes, in operation, and later the others will be started, says the Times. The capacity of this plant is 225 tons daily, and is supplied with mineral from the Tom Boy mines proper. The company has bought the Mountain Chief claim, adjoining the Belmont on the north, which adjoins the Tom Boy, for $100,000. This claim is on the Tom Boy vein and is thought to contain a continuation of the ore shoot that exists in the Belmont and Tom Boy. It will be opened up and the ore handled through the Belmont and Tom Boy workings. The company's other plant has sixty stamps dropping regularly, crushing 175 tons per day. Its supply of ore comes from the Argentine and Cincinnati.

There are 450 tons daily of mineral being sent down over the wire rope tramway from the Smuggler-Union mines, near Telluride. This supply is keeping the new 60 stamp mill and forty stamps of the old mill dropping regularly. The main portion of the gold values are saved on the mill plates by amalgamation, and the concentrate shipments from the two mills amount to two and a half carloads daily, says B. Wells, manager. The company has 400 men at work.

SUMMIT COUNTY.

At the Cashier mine in Brown's gulch, near Breckenridge, Manager Wood says he will reduce the cost of mining (breaking) the ore by putting in a steam shovel. To provide room for working this machine, a tunnel, 12x14 in size, is being run from the surface to the ore, which is but 50 feet under cover. The ore body will be exposed and worked like a quarry. The shovel will be operated by electricity supplied by the power house.

TELLER COUNTY.

(Special Correspondence).— The Ajax G. M. Co. at Victor has struck a flow of water in the 1200-foot level and will put in pumps before it can work at the level. It is now operating on the 1100-foot level.

The Woods Investment Co. at Victor expects to have its power plant and line completed to Pueblo by July 15th.

Cripple Creek, Colo., June 29.

It is proposed to build a cyanide mill on the east slope of Bull hill, Cripple Creek, for treatment of ore of the Uncle Sam mine. This mine has a vein 3 feet in width of $6 ore, and tests have shown it susceptible of cyanide treatment.—Lessees on the Rose Maude mine have unwatered tbe shaft. The shaft is 100 feet in depth with drifts 180 feet. Development work has started from the bottom level, where they will crosscut in two directions.

The April Fool claim on Squaw mountain, Cripple Creek, owned by the Squaw Mountain M. Co., will be developed through the Columbine-Victor tunnel, that is driven through Squaw mountain from the Eclipse gulch side to the Gold Coin mine. At present the April Fool claim is being operated through the 666-foot level of the Golconda mine.

The Prudential Gold Extraction Co. has been incorporated at Cripple Creek by T. Cornish, J. A. Dunwoody, E. P. Arthur, Z. E. Funk and J. Stovekin, the last-named being manager. The process to be used is a modified form of the cyanide process, says the Cripple Creek Times, and ore containing as low as $4 in gold can be treated at a profit. The ores will be ground to pass through a 150-mesh screen. Tbe ore is first crushed and then set into the rolls, where a weak solution of cyanide is permitted to run. After passing through the rolls, tbe pulp passes into a tube mill, 22 feet long and 5 feet in diameter, and containing five tons of steel balls. Leaving the tube mill, the pulp passes into agitation tanks (four in number). Before the pulp reaches the agitation tanks, however, it is said that 75% of the values will have been extracted. In these tanks agitation will keep the pulp in constant motion, and there will be no chance for the pulp to cake or settle and it will be exposed to the free oxygen in the air that it is constantly in contact with. After passing through the agitation tanks the pulp is conveyed to a large settling tank and from there passed through a filter press, in which 80% of the solution is secured with the first pressing.

The Accident mine on Gold hill, Cripple Creek, adjoining the Pointer and Mint groups, is being worked under a bond and lease by B. F. Hickman through the third and fourth levels of the Pointer group. The lessee is following an 18-inch shoot of ore that runs three ounces gold per ton, and is making shipments.

It is reported the Stratton Cripple Creek M. & Dev. Co. intends to build a cyanide mill on Globe hill, near Cripple Creek, to treat bodies of low-grade ore exposed in the various workings of the properties owned by the company. It is claimed no leases will be granted on the parts laid out on this hill.

E. M. De La Vergne, president of the Mary Nevin G. M. Co , reports two leases granted on their ground on Beacon hill, Cripple Creek. The first lease was to the Hanover L. Co., H. Granfield manager, on the south 100 feet of the Mary Nevin and Hibernia claims for three years. It is the intention of the lessees to sink a shaft 300 feet and from that depth prospect the property. The second lease was to Coe & Co. of Cripple Creek on the north 500 feet of the group for two years at 25% royalties.

At Victor the El Paso-Gold King mine in Poverty gulch is making steady shipments of ore, although the lower levels are filled with water. As soon as the pump, capable of hoisting water at the rate of 1500 gallons a minute from depth 1000 feet is set up, the shaft will be drained to the 900-foot level, when drifts will be extended on the shoot.

Nearly all the men at the C. K. & N. group at Cripple Creek were laid off temporarily last week, as ore blocked the bins. Besides the congested condition of bins, water is proving a hindrance.

The month of June showed a total of 650 feet additional driven on the Cripple Creek drainage tunnel, leaving 1035 feet to complete by August 25, the time limit. S. S. Bernard of the El Paso M. Co., which has the contract, has fifty-five men at work on the drainage tunnel and 180 men in the El Paso mine and tunnel. The entire length of the tunnel, south of the El Paso mine, is 4063 feet. They are driving all the headings under company contract, two sub-contracts having been canceled.

Development work will be increased on the Sunshine and Sedan mines, on Galena hill, near Cripple Creek. Shafts are being straightened and enlarged. Ore of both mining and smelting grade is obtained.

IDAHO.

BANNOCK COUNTY.

A strike of copper ore is reported to have been made in the Fort Hall group, 8 miles southeast of Pocatello. The strike was made in a tunnel at 650 feet and at depth of 250 feet from the surface.

BOISE COUNTY.

A Chilean mill has been set up at the Engle Co. mines near Grimes Pass, near Idaho City. Its capacity is sixty tons per day.

At the Twin Sisters mine at Centerville the mill has been shut down temporarily pending changes in equipment.

W. Frame, foreman of the Golden Chariot mine, on Rock creek, near Idaho City, says the shaft is down 150 feet. A crosscut will be run to the ledge from the 100-foot level. Ore is coming from one of the tunnels on the Cleopatra claim. A raise will be driven 100 feet to connect with the shaft.

IDAHO COUNTY.

Manager H. D. Rankin, of the Rankin R. Co., in Rapid River district, near Warren, says they expect to have their mill and electrical plant in operation by July 15th. All their buildings will be lighted by electricity. He proposes also to introduce electric amalgamation. The dynamos will be connected with the amalgamating tubs. An 8 H. P. ammonia compressor will also be added, by which the water which cools the acids used in the process can be cooled to near the freezing point.

D. McKenzie reports sylvanite found in the Independence mine on Big creek, in Thunder Mountain district, near Roosevelt.

KOOTENAI COUNTY.

A. Klockmann, managing director of the Idaho-Continental mines, on Mount Klockmann, near Port Hill, reports the lower drift in the Blue Joe tunnel in 600 feet, and a vertical depth of 400 feet obtained. The ledge is 30 feet wide, and outside of a streak of high-grade galena 1 foot wide, it is all concentrating ore. The shoot averages $40 per ton. In the upper levels at top of hill he has suspended development, as a large body of galena has been shown, and it is intended to open the mine at depth. It is proposed to build a railway from Port Hill and a concentrator near the mine.

OWYHEE COUNTY.

Further equipment is being put in by the McKinnon G. M. Co., near Silver City. The company's group is on War Eagle mountain. A tunnel has been started to tap four veins of ore.

Work is under way on the Fourth of July group of claims on War Eagle mountain, near Silver City, and owned by J. C. Connors, E. E. Beebe, J. Hogan and W. D. Evans. They report having a 6½-foot vein that assays $15 and shows free gold.

SHOSHONE COUNTY.

An electric transforming station will be built at the Hecla mine at Gem, says Superintendent F. Phair of Spokane, Wash., and power will be obtained from the Washington Water Power Co. There are 130 men and teams at work on construction of the electric line between Gem and the Spokane power station.

The vein on the Alameda mine on the east fork of Nine Mile, 5 miles from Wallace, was struck last week and the full face of the tunnel is showing galena. The tunnel is in 480 feet at depth of 300 feet. Development work has also been carried on in the upper workings. W. Farmer is principal owner.

KANSAS.

MONTGOMERY COUNTY.

J. M. Parker of Colorado Springs, Colo., manager of the Vulcan Oil & Gas Co., operating near Independence, says they have three drilling outfits at work. They have three wells down, two of which are yielding a flow of 1,500,000 cubic feet of gas a day and one well which is pumping ten barrels. There are twenty-two brickyards alone operating in the gas belt, every one using gas for fuel. The Panther Place well is yielding 15,000,000 cubic feet of gas a day with a natural pressure of 630 pounds. The Independence Oil & Gas Co. has six wells that are supplying the town of Independence with fuel and light. In addition, around Peru, there are twenty-five wells that have been pumping five years and are yielding 350 barrels a day. The Standard Oil Co. has laid a 125-mile pipe line through the center of the oil and gas belt and is running laterals out to all the adjacent country to collect the oil for the 5000-barrel-a-day refinery.

MICHIGAN.

KEWEENAW COUNTY.

The Miskwabik Dev. Co., the Federal Copper Co. and the Union Land & C. M. Co. have been consolidated in Boston, Mass., as the Miskwabik M. Co., with H. F. Fay, president. Work has begun on the mines with L. L. Hubbard as manager.

MISSOURI.

JASPER COUNTY.

A good body of zinc ore is being opened up at depth of 15 feet on the Hannum & Hayworth lease, near Alba, 12 miles northeast of Joplin. — A strike is reported on the Pin-Mays lease near the South Carthage mines, 4 miles southeast of Carthage, where an ore body was opened at 15 feet and extended to the 100-foot level.

The Moss Rose mine, owned by Joplin men, with W. Armington as manager, is reported making $500 a week with six hand jigs. The Moss Rose is on the Granby land, near Joplin, and has four faces of lead and zinc ore.

New zinc mines are being opened up in Grove Creek valley, near Joplin, in a section noted for its shallow lead diggings in the early seventies, says the St. Louis Review.

MONTANA.

CARBON COUNTY.

In order to provide additional dumping ground for the waste from the mine, the Rocky Fork Coal Co., near Red Lodge, have changed the channel of Rock creek so as to cause the waters to flow 300 feet farther to the westward of their former course, leaving the old channel to be utilized by the company in its future operations. Besides furnishing a dumping ground for three years at least, it does away with the complaint from ranchers along Rock creek of injury caused by the dumping of coal slack into the stream.

CASCADE COUNTY.

J. L. Neihart of Neihart is making shipments of high-grade silver-lead ore to the smelter.

The Home M. Co., which is to develop claims at the head of Pilgrim creek, has

been incorporated at Great Falls. The group is of thirteen claims and the values are in gold and silver.

DEERLODGE COUNTY.

The Anaconda C. M. Co. at Anaconda reports the chimney which will carry off all the smoke and gases from their works completed. The stack is 300 feet high and the main flue is 25 feet high and 40 feet wide. The Washoe smelter was closed down July 1st in order to make the connections between the smelter and the flue. This throws 1000 men out of work at Anaconda and 2000 out in the company's mines at Butte. They will resume September 1st.

FERGUS COUNTY.

F. Wright of Lewistown, part owner, has men at work on the Santiago mine, near Kendall. B. Losinger of Malden is superintendent

The Judith M. Co. has been organized to develop mining properties in Fergus county, with headquarters at Lewistown. F. E. Smith, W. E. Wilson, A. Hayden, A. P. Pendleton, A. W. Bulkley, R. J. Walsh and J. H. Mauritius are directors.

GRANITE COUNTY.

It is reported work will be resumed on the copper mines on Copper creek, at Royal, near Philipsburg, owned by the Lexington Co. of Butte.

JEFFERSON COUNTY.

The Pittsburg-Montana D. Co., composed of Eastern men, are putting up a hoisting plant on the Evening Star mine in Cataract section, near Basin.

The Chicago and Alta-Extension M. Co. has been incorporated by H. H. Ebert, of Helena; J. W. James and C. B. English, of Anaconda; J. K. Harris, J. Leavitt, C. R. Swartout, D. C. Schnell, C. F. Craver, Chicago, Ill., to develop the Alta-Extension in Wicks district. The Alta-Extension is 1½ mile west of Corbin.

The Colorado M. & D. Co., which owns the Hidden Treasure and Copper King mines near Corbin, has arranged to put in heavier machinery and sink 200 feet and crosscut at that level. The company is composed of Butte and Chicago men.

LEWIS AND CLARKE COUNTY.

The Bismarck group of claims, 17 miles east of Helena, is being developed by K. Reeves, who has men at work taking out ore, the values being in gold.

MADISON COUNTY.

The Verna lode on Mineral hill, near Pony, is being worked by J. H. Miles, C. S. Shoemaker and W. Watt, and is developed by a tunnel and shaft. A crosscut 18 feet long has been driven to show width of the vein, which assays $8 gold and eleven ounces silver. The tunnel will be continued 150 feet farther. They also own an adjoining claim, the Jim, on the south.

R. R. Smith and F. B. Feetham of Grand Forks, North Dakota, have bought a controlling interest in the claims of Siegfried, Port & Derat, near Alder gulch. They intend to build a mill should development work warrant. All of the claims are gold bearing.

L. D. McCall of Chicago, Ill., and W. M. Brown of Virginia City, Mont., owners, will put up a 15-stamp mill to treat the ore of the Gold Coin, U. S. Grant and Fairweather mines, near Pony.

MISSOULA COUNTY.

The Golden Chance M. Co. has been incorporated, with headquarters at Wallace, Idaho. J. B. Phinney, T. H. Thomas, C. A. Stillinger, N. A. Moderi and W. Beach are directors. The company owns a group of claims in Missoula county.

PARK COUNTY.

The 80-stamp mill and cyanide plant of the Kimberly-Montana M. Co., at Jardine, is in operation and work resumed at the mines. The Kimberly-Montana Co. is composed of Chicago men and is a reorganization of the Bear Gulch Co.

The St. Julian G. M. Co. will build a 10-stamp mill on their group at Emigrant, near Livingston, this summer. They expect to be able to handle 100 tons of ore daily.

NEVADA.

LANDER COUNTY.

Superintendent Simpson has the cyanide works at Pittsburg, near Battle Mountain, treating the tailings of the Pittsburg Co. mines.

The Marysville mines, owned by R. Kirman and C. E. Mack, are being worked with J. A. Logan of Carson as superintendent.

At the Dean mine (the Morning Star mine), at Battle Mountain, owned by W. E. Dean of San Francisco, Cal., the 10-stamp mill is running steadily, crushing thirty-five tons a day. It is proposed to increase the capacity, says Manager D. J. Bousfield.

LINCOLN COUNTY.

At Pioche, S. Bamberger of Salt Lake City, Utah, has bought a one-half interest in W. H. Clark's Great Eastern paint mine and all of the Richman mine (formerly the No. 9) Bamberger also bought the Black Prince mine.

NYE COUNTY.

G. W. Wood, manager of the Piute M. Co. of Mammoth district, 3½ miles west of Ellsworth, says the company has men on contract in crosscutting and doing development work, and will put on more men this month. A mill will be erected at the mine during the summer. Wood and water are plentiful at the mine.

The Le Beau mine, east of the Piute, was sold last week to C. Peters of Tonopah for $30,000. The ore in the Le Beau is free milling and averages $50 in gold. The development work consists of a 40-foot shaft.

WASHOE COUNTY.

J. Mack has bought a half interest in the Lion mine east of Reno, F. Knoblock being the other owner. It is a copper mine and work will be resumed in the tunnel next week.

WHITE PINE COUNTY.

Machinery for the stamp mill for the Wide West M. Co. is being set up on the millsite at the mouth of Egan canyon, near Cherry Creek, says Superintendent Leisman.

OREGON.

BAKER COUNTY.

The E. & E. mine, at Bourne, will resume, says Superintendent J. Thomas, after being idle four years. Repair work is under way and full operations will begin by Aug. 1.

The Gem mine and mill, near Baker City, has been bonded to H. T. Hendryx of Sumpter for $90,000.

Superintendent H. W. Nelson of the Alpine M. Co., near Sumpter, reports preparations being made to put in additional machinery.

W. C. Bass, superintendent of the Maxwell mine, near Sumpter, says operations have resumed at the 10-stamp mill.

Superintendent J. J. Hennessey of the Gold Bug-Grizzly mine, near Sumpter, finished last week and is sinking an additional 200 feet. They will cut out stations on the 200-foot and 300-foot levels. No effort will be made to crosscut to the vein while sinking.

GRANT COUNTY.

Two tunnels are being driven on the Big Producer group, near Alamo, says Manager W. H. Chambers. The crosscut on the Moulder Boy is in 500 feet, cutting three veins in that drive, and the drift on the Boston vein is 300 feet long.

Near Susanville, the Badger Co. will put a mill on the Bull of the Woods mine, adjoining the Badger, which they also own. The Badger plant is running full capacity.

JOSEPHINE COUNTY.

The Alameda M. Co. report developments progressing on their gold-copper mine, near Galice.

MALHEUR COUNTY.

At the Black Eagle mine, near Malheur, Superintendent J. F. Meikle says the 20-stamp mill will be increased to forty stamps.

NEW MEXICO.

GRANT COUNTY.

J. C. Woodward has sold a three-quarter interest in his Casino group of mines to Los Angeles men for $110,000. There are fourteen claims and a millsite in Bald Mountain mining district, 9 miles southeast of Silver City. Further development work will be done, with Woodward in charge, and they will build a mill.

A. R. Gibson of the American Con. C. Co., operating near Lordsburg, says at the Atwood mine, owned by the company, machinery has been put in, including pump, boiler, pipes and tanks. Reduction works are proposed to be built in the fall. A road has been built, shortening the haul between the mine and Lordsburg.

SOCORRO COUNTY.

The Cavern G. M. Co. has been incorporated at Albuquerque by G. L. and H. O. Brooks of Albuquerque and B. A. Statz of Kelly, to operate near Kelly.

SOUTH DAKOTA.

LAWRENCE COUNTY.

C. E. Heizer, of the Spearfish G. M. & R. Co., near Spearfish, says they are successfully treating the low-grade deposits of ore of that section. The company propose considerable deep development and will sink several shafts to depth of 400 feet to open and explore the limestone existing at that depth. The Portland mine, adjoining the Spearfish, has cut the zone with its workings and opened good ore.

The Big Four M. Co., operating on Deadwood gulch in the phonolite belt, near Deadwood, says Manager J. P. Beach, are putting in a steam hoist, boilers, air compressor, air drills and an electric lighting plant. Sinking will be resumed in the shaft, which was put down with a whim. P. T. Bird of Deadwood is superintendent. It is intended to go down 500 feet and explore the phonolite bodies that appear at the surface.

PENNINGTON COUNTY.

The Grizzly Bear mine, near Hill City, has been cleared of debris and caved earth by the Lakota Co. of Peoria, Ill. The 10-stamp mill has been torn down and the company is preparing to build a 20-stamp mill on the site, to be connected with the mine by aerial tramway. The mine workings have been straightened and extended and made ready for permanent work.

UTAH.

BEAVER COUNTY.

President S. Newhouse says excavation work will be started next week for the 1000-ton concentrator and smelter to be built to treat the ores of the Cactus mine, near Frisco. They will also lay a pipe line to convey the waters of Wah Wah spring across the desert valley below to the smelter site.

President A. B Lewis, of the Imperial M. Co., operating near Frisco, reports an ore strike in the shaft which is going down at the mouth of the Massachusetts tunnel in Lœber gulch. The ore body shows assays of 10% copper, with 20% lead, 18 ounces silver and $3 gold. The Comet shaft has been unwatered, and at the 200-foot level crosscutting to the ledge begun, the shaft also to be sunk.

The Royal Co. has taken an option on the Lindsay group of ten copper claims in Rocky district, near the Old Hickory and Montreal mines near Milford, for $10,000.

SALT LAKE COUNTY.

The Butler-Liberal Con. M. Co. has been incorporated at Salt Lake City, being a consolidation of the Ben Butler M. & M. Co. and the Chicago & Bingham M. Co., both of West Mountain mining district, near Bingham. A. L. Jacobs, C. N. Strevell, E. D. N. Thompson and W. S. McCornick are officers.

SUMMIT COUNTY.

At Park City work is under way on the site of the former zinc plant for the erection of two temporary buildings for working the ores that were in the building at the time of the fire. One will contain the rock breaker and other machinery, while the second building will contain the electrical apparatus for separating the metals, etc. This plant, says the Record, will be operated until the contracts with the mining companies expire (October 15). In the meantime it is expected that satisfactory arrangements will be reached by the Park City Metals Co. and the Park City mine owners, who will furnish the necessary ores, in which event plans will be prepared and a large plant built.

The remodeled and enlarged mill of the Daly-Judge M. Co. at Park City was started up last week and is handling 300 tons a day, says Mill Superintendent Sherman. Mine Superintendent Dunyon has put on more men underground.

A two-years lease and bond for $100,000 has been given on the Bonanza Con. group of claims, near Park City, and the Imperial M. Co. incorporated by A. B. Taylor and W. D. Sutton to work the group.

WASHINGTON.

FERRY COUNTY.

E. L. Tate, of the Quilp M. Co., at Republic, reports shipments being made at the rate of 100 tons a day, and there are fifty-seven cars now on the road or at the smelter, on which they are waiting returns. Since shipments began in October, 1902, the Quilp has produced 8000 tons, during which period there was the tieup on account of coke famines at the smelters. The ore averages $14 per ton, with one-third of the values in silver. At the 620-foot level the mine is showing a streak 2½ feet wide, of ore which has been drifted on 90 feet, and a winze is being sunk in it. A carload shipment from it assayed $74. It shows native silver.

OKANOGAN COUNTY.

It is reported the Palmer Mountain G. M. & T. Co., on Palmer mountain, near Loomis, is planning to put in a stamp and cyanide plant of 300 tons daily capacity, with electrical power. The tunnel will be driven 5000 feet farther.

Superintendent J. P. Blaine of the Opal M. Co., near Chesaw, says he has two shifts at work in the lower tunnel at the Opal mine. This tunnel is in 175 feet and is being driven towards a point in the ledge under the upper tunnel. The upper tunnel is in 190 feet. The ore shows values in gold, silver and copper. It has been decided to put in a concentrating plant in connection with which will be a cyanide mill.

The shaft being sunk to the 100-foot level in the Great Western mine, near Nespelem, is in ore, says M. L. Pershall of Spokane, president. The lead is 7 feet wide and assays $35. Shipments will be started in August. Besides this high-grade ore the company has a body of $10 ore which can be concentrated.

STEVENS COUNTY.

Work is under way on the Golden Sun mine on Big Sheep creek near Northport, says Superintendent D. Bennett, who is driving the tunnel 100 feet farther into the mountain.

At Newport, the Bead Lake tunnel is in 1400 feet, and work is progressing. Some quartz is being struck and it is expected the main vein will be cut by August 1st. ——The Conquest mine has a double-compartment shaft down 50 feet, and as soon as the machinery is set up development work will be increased.——The Ballerat tunnel is in 220 feet.

R. W. Hunner of Republic, for J. J. Hill of the Great Northern R. R Co., has bonded the Combination and Golden Zone iron claims, in Wolf's camp, on the Colville reservation, and 1½ mile from Curlew lake. The deposit of iron, where the lime capping has been crowded, is shown in places to be 1200 feet wide. The ore is hematite, running 62% iron.

WYOMING.

ALBANY COUNTY.

The Acme G. & C. M. & M. Co., organized to take over the interests of the Wyoming D. & T. Co., which operated at Gold Hill, southwest of Laramie, has been incorporated. The Acme Co. owns the Acme and other mines at Gold Hill. The Laramie, Hahn's Peak & Pacific railroad is being built southwest of Laramie, and as soon as the line is completed to Gold Hill work will be resumed in the mines there.

CARBON COUNTY.

At Grand Encampment, the concentrator of the North American C. Co. was started up last week, and the roaster, briquetter and smelter followed later on. The tramway is bringing the ore down from the Ferris-Haggerty mine at the rate of 200 tons per eight hours, three shifts of men being at work at the mine and at the terminal at Encampment. An air compressor for the Ferris-Haggerty mine is being set up. It has a capacity of 2000 cubic feet of air per minute, and will operate twenty-five drills, each of which is expected to break twenty tons of ore per day. There are three levels in the Ferris-Haggerty mine where the drills will be used.

An explosion of fire damp in mine No. 1 of the Union Pacific Coal Co. at Hanna, June 30, entombed 282 men. Of these forty-eight were rescued alive. Of the remaining, 100 were Finlanders, fifty colored, and the balance white Americans. The mine was not fired, but the explosion shattered the timbers of the main shaft and entrances, and filling the workings with debris. No. 1 mine has twenty-six entries, 15 miles of workings, and a main incline shaft 1½ mile in length. E. S. Brooks is superintendent.

FOREIGN.

AFRICA.

CAPE COLONY.

Copper returns for May show: Ookiep mine, 1816 tons of 16% (270 tons of fine copper); Nababeep mine, 2584 tons of 6% (144 tons of fine copper.

RHODESIA.

Red & White Rose Gold Co. May output: Mill working thirty days obtained 1137 ounces of gold from 3222 tons of ore crushed. Recovered by cyanide 435 ounces from 2201 tons.

Rezende mine, May output: Twenty stamps running twenty-nine days crushed 3350 tons; recovered from mill 1102 ounces fine gold; recovered from tailings by cyanide 107 ounces; in addition 10 ounces of concentrates were produced containing 45 ounces fine gold.

Bonsor gold mine May output was: Fifty stamps ran twenty-nine days, crushing 5010 tons, gained 1091 ounces; treated by cyanide 3190 tons yielding 416 ounces. Globe & Phœnix Gold report during month of May mill ran 28 6 days, crushing 6698 tons of ore; yield 3723 8 ounces bullion; tailings, average assay value per ton 2 61 dwts. fine gold; cyanide, tons treated, 4600, yield 447.3 ounces.

SOUDAN.

A discovery of iron ore is reported in Bahr-el-Ghazal Province. The analysis of specimens brought to the office of Count Gleichen, director-general of the Soudan Government Intelligence office, gives 43.47% of iron. U. S. Consul-General G. Long at Cairo, reports iron is found in the Soudan, in Kordofan, Bahr-el-Ghazal, Darfur Provinces, and on the Abyssinian border. In Kordofan there are two ore beds, one 60 miles northeast of El Obeid and the other 60 miles northwest. The ore is brown hematite (limon-

ite) and is found in small fragments at a little depth in the sand. There is no fuel or material for building furnaces at hand, nor could it be shipped with profit without a railway. It is not worked at present except in small quantities by the natives. ——In Bahr-el-Ghazel the Bongo country lies between 6° and 8° north latitude on the southwestern boundary of the depressions of the Bahr-el-Ghazal basin, and on the lowest terraces of ferruginous crust bordering on alluvial land. Much of the time of the natives is devoted to the working of iron; which is found in great abundance in Bongoland. They manufacture arms and tools of good quality. Their smelting furnaces are made of clay, and the iron is afterwards worked on anvils of gneiss or granite by hammers of stone or iron, rude bellows being used. The Jur country, northeast of Bongoland, now sparsely inhabited, is the lower terrace of the iron-bearing formation, from which the natives extract a large quantity of iron. They produce a metal of good homogeneity and malleability. Iron smelting is done in March, just before the sowing season. In Darfur the method of working the iron ore is identical with that used in Kordofan, but it appears to be inferior in quality and very brittle. On the Abyssinian border iron ore is extracted in the plains surrounding Fadassi (on the Ahyssinian side of the border, south of Beni Shandul) at some depth from the surface. The occurrence is similar to the hog-iron ore found in Kordofan. The Gallas work this ore into iron, as in Kordofan.

TRANSVAAL.

Angelo Gold Co. May report show: Sixty stamps crushed 8178 tons; recovered 3011 ounces; 6963 tons treated by cyanide for 2724 ounces.——Bonanza mine May results were 8120 tons crushed, yielding 4100 ounces; from cyanide and slimes works, 8120 tons treated, yielding 2565 ounces.——The Cassel Coal Co.'s May output was 10,068 tons.——The Crown Deep mine, near Johannesburg, May results give: 135 stamps working twenty-nine days twenty-two hours crushed 21,238 tons, yield 4631 ounces; 14 840 tons of sands and concentrates treated hy cyanide works for 2968 ounces; 5323 tons of slimes treated, yield 423 ounces.——At the Driefontein Con., during May, 110 stamps crushed 13,662 tons for 3870 ounces; 9268 tons treated hy cyanide for 3374 ounces. ——The Ferreira Gold Co., near Johannesburg, report for May eighty stamps running 28 98 days crushed 11,515 tons, yieiding 4757 ounces gold and 210 tons concentrates, yielding 691 ounces; 7560 tons sand treated for 1523 ounces; also 3387 tons slime, yielding 527 ounces.—— The Langlaagte Estate & Gold Ltd., near Johanneshurg, report for May 150 stamps running twenty-nine days crushed 21,784 tons for 5731 ounces gold: tailings cyanided, 14,850 tons for 1616 ounces; concentrates cyanided, 566 tons for 1082 ounces — total gold value, £35,823.—— The Robinson Gold, near Johannesburg, May results were: 135 stamps crushed 18,832 tons, yield 8809 ounces; yield from tailings hy cyanide, 3606 ounces; yield from concentrates (by chlorination), 840 ounces; yield from purchased concentrates, 869 ounces.——Jumpers Deep, Ltd., May results show: Ninety-five stamps working thirty-one days crushed 15,633 tons; yield, 2952 ounces; 9950 tons of sands and concentrates treated hy cyanide for 1988 ounces; 5367 tons of slimes treated for 376 ounces.

At the Durban-Roodepoort Gold, near Johanneshurg, May results were: Quartz milled, 8540 tons, seventy stamps, twenty-seven days, 4298 ounces gold produced; tailings treated, 5865 tons for 965 ounces. ——Transvaal Coal Trust report May output at 26 900 tons.——The Van Ryn Gold Co., near Johannesburg, report crushing begun with thirty head of stamps June 1.

The May output for the gold mines amounted to 234,125 ounces, being 224,409 ounces from the Witwatersrand and 9716 ounces from outside mines. This gives a total for 1903 to June 1 of 1,075,253 ounces.

WEST AFRICA.

Ashanti Gold Fields Corporation, Ashanti, report, May crushings: Ohuassi mine, 1540 tons for 2310 ounces gold. Development work, 1230 tons crushed for 530 ounces ——Ashanti Sansu crushings for May, 1800 tons, producing 1910 ounces.

AUSTRALIA.

VICTORIA.

The gold yield of Victoria for 1903 to June 1 amounted to 308,733 ounces—an increase of 31,169 ounces compared with the corresponding period of 1902.

WEST AUSTRALIA.

The Kalgurli Gold Co. at Kalgoorlie report that during the month of May 4050 tons were treated for a return of 3878 ounces of gold of standard fineness (£15,028); expenditure for the month as follows: Working expenses £5817 10s; development £545: capital expenditure £490. On the 1000-foot level north drive the stope in the back of the level is producing ore assaying 2 ounces gold; 850-foot level east crosscut, south drive, is in ore of 17 dwts. per ton; width of ore is 27 feet; west crosscut is in ore of 19 dwts.

At the Sons of Gwalia, Ltd., mines at Leonora the 60-stamp mill crushed during May 8018 tons of ore for 4444 ounces of gold, value £16,872; tailngs treated by cyanide 4500 tons for 1381 ounces of gold, value £5227. Working expenses for May were £8428 (21s. per ton), divided as follows: Mining (including pumping) 11s. 10d.; treatment (including milling, cyaniding and concentrating) 5s. 10d.; general expenses, 3s. 4d.

QUEENSLAND.

The Queensland gold returns for month of May show:

Mine.	Tons Crushed.	Yield in Ounces.
Charters Towers	25,600	40,200
Croydon	4 800	5,700
Gympie	19,100	20,100
Mount Morgan	19,400	10 800
Ravenswood	2,400	4,600
Other fields	4,000	4,800
Alluvial		900
Total	75,300	89,100

BRITISH COLUMBIA.

S. H. C. Miner, president of the Granby Con. Co. of Grand Forks, says within twelve months, when their coke ovens in Alberta are in operation, they will be able to lay down copper in New York at a cost of 7 cents a pound.

The Rossland-Kootenay Co. has men at work at the Great Western mine, near Rossland, which has been idle for three years. There is a mile of underground workings driven and low-grade ore bodies are shown. It is the Rossland-Kootenay's intention to unwater the mine and prospect the ore bodies already blocked out.

The coke shortage at the smelters handling ores from Rossland camp continues to check the output, as well as development work. The Kootenay mine, which had plans prepared for building a $25,000 tramway from the mine to the Canadian Pacific railway, has postponed action thereon, as the smelter is unable as yet to figure on a steady coke supply.

The Perry Creek M. Co., near Fort Steele, has men at work cutting a right of way for a 3-mile flume, for which their sawmill is cutting lumber.

Hydraulic mining on Finley creek, near Fort Steele, is being carried on with a canvas hose and wooden nozzle by Superintendent C. Chapman.

G. B. McAulay of Spokane, Wash., and J. Moran of Greenwood, owners of the Copper Mine mineral claim, 6 miles west of Greenwood, in Copper Camp, will resume work next week. It is also reported D. C. Corbin intends resuming on the King Solomon claim, adjoining the Copper Mine, from which some copper ore has been shipped.

Y. Emery of San Francisco, Cal., is reported making arrangements to open up the Newcastle Island quarries, near Nanaimo, to get out building stone.

The Tyee smelter at Ladysmith, after a successful run of four months, has closed down temporarily, to clean boilers, water-jackets and overhaul machinery, and allow the ore on the roast piles to accumulate for another and longer run. A second cage has been put in at the mine, so that ore shipments will be increased.

W. T. Smith has men at work on the Bell mineral claim, on Wallace mountain, near Beaverdell, on West Fork of the Kettle river.——Tuzzo & Currie have opened up a lead across their Comstock group, also near Beaverdell, and Palmer & Rambo, on the Ella E. claim adjoining, report work progressing.

The work of unwatering the Athelstan mine, in Wellington camp, 3 miles from Phœnix, was finished last week, and Foreman Oxley has men prospecting the surface where it is proposed to open glory holes and ship ore, says the Spokane Review. The Athelstan is owned by the Athelstan G. & C. M. Co., Ltd. The development work on the Athelstan includes two shafts, 60 and 70 feet deep. The ore is an arsenical iron, the chief value being gold, with a little silver.

At the Wilcox mine of the Broken Hill M. & M. Co., near Ymir, the mill is crushing fourteen tons a day with four stamps and is making one ton of concentrates daily. The ore is averaging $15 gold and silver a ton and the concentrates assay $45 in gold, silver and lead a ton. The Ymir mine is dropping seventy stamps and several other properties in the camp are busy.

The provincial mineralogist's annual report for 1902, just issued, says the total output shows a falling off in value of $2,500,000 as compared with 1901, the unsatisfactory state of the metal market being one of the chief causes. Light rainfall and consequent shortage of water diminished the output of hydraulic mines, but in spite of this placer mines showed an increase of 10½%. Vancouver Island coal was affected in California, its principal market, by the competition of fuel oil. Compared with 1901 the value of ore output was as follows:

	1902.	1901.
Gold, placer	$1.073,140	$ 979,100
Gold, lode	4 888 269	4,348,603
Silver, lode	1,941,328	2,884 745
Copper	3,446.673	4,446,963
Lead	824,832	2,002,733
Coal	4,192,182	4,380,983
Coke	640,075	635,405
Other materials	480,051	417,283
Totals	$17,468,550	$20,086,780

In quantity, copper showed an increase from 27,603,000 in 1901 to 29,036,000 pounds in 1902, though there was a decrease in value. By districts there was a falling off in value with the exception of Cariboo and Cassiar, both of which are placer mining districts. Taking all lode mines into account the tonnage of ore mined in 1902 was 998 999, compared with 920,416 tons mined in 1901. This increase is due to Rossland and Boundary. The output of copper by districts was: Boundary, 14,-955,582 pounds; Rossland, 11 667,807; coast, 2,496 681; Nelson, 491,144; other districts, 24,483 Iron ore has been mined on the coast during the past year, but the only shipments made were from Texada island, from which 6290 tons of magnetic iron ore, running 50% iron, were sent out. From the iron mines at Cherry creek, near Kamloops, 3727 tons of magnetite were shipped to Nelson, for use in the smelter as flux. The total number of accidents in metalliferous mines during the year was twelve. In the collieries the fatal accidents numbered 139; of these 125 deaths were due to the explosion in the Crow's Nest collieries in May, 1902. In ten years 321 miners have lost their lives in British Columbia collieries.

At Fernie the Crow's Nest Pass Coal Co. is operating three coal mines and expects to open three more next month, says the Rossland Miner. The production of coal is 1100 tons daily. "The company has 424 coke ovens, of which 144 are not now in use. The wages paid are 75 cents per oven of five and a half tons charge and 95 cents per oven of seven and a half tons charge. A man will ordinarily draw three ovens daily. The company is drawing sixty ovens daily, so that its output of coke is 250 tons. A charge is supposed to remain in the ovens seventy-two hours, but under existing circumstances the ovens are not being drawn regularly, sometimes remaining charged four or five days. Manager Tonkin states he is running short handed.' ——At Michel the company has 212 ovens in continuous operation. The stone bases are laid for 250 additional ovens, and these are expected to be in operation by September. The company has 700 men at work at Michel, of whom 200 are underground. Coke pullers receive the same wages as at Fernie. Three coal seams and two prospects are being operated.

HUNGARY.

There are sixteen copper mining concerns in Hungary, of which two State and three private undertakings supply the greater part of the metal. Formerly 80% of the copper was mined by the Government, but in the past year only 50% was so mined.

INDIA.

The Burma Ruby Co. of Burma report their May production at 94,000 loads washed, yielding rubies valued at $470,450, on which an average royalty of 32% was paid.

MEXICO.

CHIAPAS.

At Palenque the Palenque G. M. Co., an English company, have development work under way.

CHIHUAHUA.

A. H. Kennedy is putting up the electric power plant for the Terrenates Con. M. Co. of Parral. General Manager Husted has the first shipment of machinery for the plant at the mine.

A lease and bond on the Fourth of July mine in Parral district has been taken by the Saginaw M. & M. Co., who contract to sink 200 feet. This mine adjoins the Two Republics.

The English Co. has recently taken over the San Francisco del Oro mine, in El Oro section of Parral, near Santa Barbara, the principal vein of which is the Santo Tomas y Sanas, a producer. An aerial tramway is being built from the mine to the mill.

The new mill and aerial tramway of the Adele mine of W. Petit are in operation. The Cuadras mine of the Guggenheims is the extension of the Santo Tomas y Sanas vein. Both veins carry gold, silver and lead values, with some copper.

J. C. Brooks has commenced work on the San Diego mine, near the town of Santa Barbara. He has shipped two carloads of ore.

DURANGO.

The power plant at Mapimi, for the Campania Minera de Penoles, is finished and will furnish power for the Ojuila mine.

GUERRERO.

Manager E. D. Elson of the Mitchell M. Co., operating a copper group 35 miles inland from Acapulco, says tunnel No. 2 is showing black sulphide assaying well in copper. Shaft No. 2, at depth of 310 feet, cut black sulphide showing 12%, and tunnel No. 8 also has similar ore. Shaft No. 7 has red oxide of copper, giving the company a total along the ore body of 3000 feet, from tunnel No. 2 to tunnel No. 8.

It is reported that from the Inguaran mine the Rothschilds, who have a large body of 2 5% to 3% copper ore, will build a road to the coast at the mouth of the Balsas river, where they will build a smelter.

MORELOS.

In Aldame district the Trinidad M. & S. Co. is putting in a cyanide plant.

SONORA.

(Special Correspondence).—It is stated that mining development of La Cananea property is satisfactory, so much so that the company is making plans for doubling the capacity of its plant, including the building of a large, independent power and crushing plant, and another concentrator of 800 tons daily capacity, which, when completed, will give the works a daily capacity of 1600 tons of concentrating ore. The smelters are producing eighty to eighty-five tons of copper daily. Dust chambers are being built and a large, self-sustained steel stack is also going up. L. D. Ricketts is consulting engineer on concentrating and is in charge of the improvements and extensions now going in.

Cananea, June 29.

N. S. Finch, agent, has bought a prospect called Mulatos in the municipality of Baxiacora, 120 miles south of international line, on the Sonora river.

The Greene Con. C. Co. at Cananea propose to build a brick dust chamber 500 feet square, to be utilized for precipitation of copper particles that have heretofore gone up with the smoke.

It is reported that the customs smelter at San Javier, W. Luebbert superintendent, will be enlarged.

At La Blanca, near Suaqui Grande, F. E. Dickenson, manager for La Blanca M. Co., says work in both the mine and on the reduction plant is progressing. The main shaft is down 175 feet and there are 1300 feet of underground development work connected therewith. The concentrating and smelting plant, with a daily capacity of forty tons, is expected to start up by September 1st.

R. L. Benton, superintendent of the Lucky Tiger-Combination M. Co., operating near Nogales, Ariz., says they are running a tunnel which will tap the main ledge at depth of 300 feet. It is in 120 feet, with 200 feet yet to drive. Some free-gold ore has been struck.

ZACATECAS.

At the hacienda of the mines bought by the Stillwell M. Co., at Zacatecas, they have taken from a fifth of the space, 18x20 feet, formerly occupied by some tanks, 193 flasks of quicksilver. If the rest of the space is equally valuable it is expected $100,000 worth of that metal would be recovered. This does not include what is expected from the old patio, 300x400 feet, where the ores of the district had been treated for nearly a hundred years.

NEW ZEALAND.

The Talisman Con. M., Ltd., May returns show 3300 tons of ore crushed for £6298 bullion. Expenditures for the month were: Mining, £1786; milling, £1943; construction, inciuding cost of alterations to cyanide plant and additions to concentrating plant, £1609; mine development, £825. The mill ran for twenty-six days, and owing to alterations to the treatment plant but thirty-eight stamps were dropped.

RUSSIA.

The British Vice Consul at Poti in his report for 1902, states the stock of ore on Jan. 1, 1903, at the manganese mines at Tchiaturi was 250,000 tons, which is estimated to cost the holders 7 copecks per pood (($2.25 per ton.) The manganese ore produced during the year having been mined with greater care than in previous years, the average quality is higher. There has been no serious attempt made by any foreign or Russian firms to secure manganiferous land in large enough plots to be able to work on an extensive scale. The exporters are numerous, and ore is secured by them in Tchiaturi from the small dealers and land owners. Steamers at Porti are almost entirely loaded direct by ore wagons from Tchiaturi.

PERSONAL.

H. T. HENDRYX of Sumpter, Or., is in the East on mining business.

J. A. VEATCH, a mining man of Beaumont, Tex., is in San Francisco, Cal.

J. M. HENTON of Deadwood, S. D., is examining mines in Durango, Mexico.

J. THOMAS is superintendent of the E. & E. mine, near Bourne, Baker county, Or.

W. B. PITTMAN of Tonopah, Nev., is in San Francisco, Cal., on mining business.

M. D. STACKPOLE of the Gold & Silver Extraction Co. is in Montana from Denver, Colo.

F. F. ARCHIBALD of London, England, of the Tarsis C. Co. of Spain, is at Clifton, Ariz.

A. FITZGERALD is superintendent of the Kenton mine at Alleghany, Sierra county, Cal.

J. L. BRYSON, superintendent of the Mazeppa mine, near Stent, Cal., is in San Francisco, Cal.

C. C. SHUBERT, manager of the Jualpa mines, near Juneau, Alaska, is at Juneau from the south.

R. D. YOAKUM of St. Louis, Mo., returned last week from a trip through Sonora, Mexico.

W. H. MARTIN has resigned as superintendent of the Sierra Queen mine, near Nevada City, Cal.

F. M. STONE, manager of the Alaska Treasurer Co., is at their mines on Douglas Island, Alaska.

G. W. SMITH of Florence, Colo., manager of the Ojo Calientes M. Co., is at their mines in Mexico.

W. B. DOUGALL, JR., of the Ima M. Co., returned last week to Salt Lake City, Utah, from New York.

W. H. SPRINGER of Spokane, Wash., has returned from an examination of mines at Rossland, B. C.

W. MCDERMITT returned to Salt Lake City, Utah, last week from an examination of mines at Pioche, Nev.

P. L FEARN of New York of the White Knob C. Co. is visiting the mines and smelter near Mackay, Idaho.

G. HURST of Redding, Cal., is superintendent of the Three Peaks M. Co. near Carrville, Trinity county, Cal.

W. T. WATTS has returned to San Francisco, Cal., from examination of oil territory in Marin county, Cal.

D. D. MILLER is superintendent of the Sierra Queen mine, near Nevada City, Cal., vice W. H. Martin, resigned.

C. C. DERBY, manager of the Mariposa Estate Co., is in San Francisco, Cal., from Mt. Bullion, Mariposa county, Cal.

JOHN B. FARRISH, E. M., of Denver, Colo., has returned from Mexico to San Francisco, Cal., and left for Denver.

J. W. TRUSCOTT has resigned as superintendent of the South Eureka mine at Sutter Creek, Amador county, Cal.

WALDEMAR LINDGREN, of the United States Geological Survey, is at Cripple Creek, Colo., from Washington, D. C.

T. L. WISWALL of Denver, Colo., is in Salt Lake City, Utah, in the interest of the Green Reduction Co. of New York.

PRESIDENT E. M. HOLBROOK of the Horsesboe M. Co. returned to Deadwood, South Dakota, last week from the East.

W. M. LUCAS of St. Louis, Mo., is at Juneau, Alaska, superintending the erection of a stamp mill on the Jennie Reid mine.

D. MCVICHIE, manager of the Bingham Con. M. & S. Co., returned to Salt Lake City, Utah, from an Eastern trip last week.

W. B. MUCKLOW of Hartford, Conn., president of the Majestic C. M. & S. Co., is at their mines near Milford, Beaver county, Utah.

W. W. WHITING, Western manager of the Diamond Rubber Co. of Akron, Ohio, has returned to Denver, Colo., from San Francisco, Cal.

G. B. CROOKS of San Francisco, Cal., representing F. W. Braun of San Francisco and Los Angeles, Cal., is in Salt Lake City, Utah.

J. M. PARKER AND S. R. BARTLETT of Colorado Springs, Colo., of the Vulcan Oil & Gas Co. are visiting the oil fields at Independence, Kan.

H. R. HAWKINS of St. Louis, Mo., is at San Quentin, Lower California, Mex., putting in a hydraulic plant on the Socorro placer claims.

F. L. RANSOME, of the United States Geological Survey, is in Cripple Creek, Colo., assisting Waldemar Lindgren in a resurvey of the district.

W. H BREVOORT of the Siberian M. Co. has gone to New York from the Greenback M. Co mines at Grant's Pass, Or., on his way to Siberia.

H. MOORE, late of the Mazeppa mine, near Stent, Tuolumne county, Cal., is superintendent of the South Eureka mine at Sutter Creek, Amador county, Cal.

J. R. CURLEY, formerly superintendent of the Iron Silver Co. and the Houghton Co. mines, is manager of the Leadville-Oro M. & L. Co. at Leadville, Colo.

C. E. HEIZER, assistant treasurer of the Spearfish G. M. & R. Co., returned to Colorado Springs, Colo., last week after a year's stay at the mines at Spearfish, S. D.

FORMER SUPERINTENDENT THOMAS of the Highland Boy smelter at Bingham, Utah, returned to Salt Lake City, Utah, from a trip to Idaho, examining mines.

MANAGER G. H. ROBINSON of the Tintic M. & D. Co. interests at Bingham and Eureka, Utah, has returned to Salt Lake City, Utah, from the East, via Chicago, Ill., and Butte, Mont.

ROBERT FRAME, formerly superintendent of the Smuggler-Union mill at Telluride, Colo., has accepted the position of foreman of mill of the Socorro G. M. Co. at Magdalena, New Mexico.

PRESIDENT MCNAIR of the Michigan School of Mines at Hougbton, Mich., returned last week after an extended trip through the copper camps of Arizona, California, Utah and Montana.

G. R. POTTER of Stevens' Point, Wis., interested in the Storm King mine and vice-president of the Enterprise M. Co, operating in southern Oregon, is at the Storm King mine near Sumpter, Or.

D. COLE of Aspen, Colo., has taken the superintendency of the concentrating plant at La Cananea, Sonora, Mexico, assuming his duties July 1. He was formerly with the Smuggler M. Co. of Aspen, Colo.

O. C. ZINNS, formerly chemist and assayer with the Penn M. Co. at Campo Seco, Calaveras county, Cal., has been appointed assistant superintendent of La Zublate mines, near La Colorada, Sonora, Mexico, and leaves for the mines on the 27th inst.

HERMAN KELLER, of the Engineering Company of America, New York, is making an examination of mining properties and smelters in Idaho, and J H. Pratt, Ph. D., of the same company, has left San Francisco, Cal., for Arizona via Los Angeles, Cal.

Commercial Paragraphs.

THE Stirling Boiler Co., Edgar Kidwell, Pacific coast manager, have moved their San Francisco office from 330 Market street to 32 First street.

HENSHAW, BULKLEY & CO. of San Francisco, Cal., report preparing a Kinkead mill for shipment to the North Star mine at Grass Valley, Cal.

THE Mine & Smelter Supply Co., Denver, Colo., through their Salt Lake City, Utah, branch, report selling a 100-ton concentrating mill for Park City, Utah.

CHAS. C. MOORE & CO., engineers, San Francisco, Cal., are in their new offices at No. 63 First street. They are contractors for complete power, lighting, heating, mining and pumping plants.

T. R. GOTH & CO, manufacturers of centrifugal pumps, in connection with the J. C. Howlett Machine Works, will occupy the new four story brick building at Nos. 256-260 Fremont St., San Francisco, Cal.

THE Jeanesville Iron Works Co. of Jeanesville, Pa., report that the Copper Glance M. Co. of Bisbee, Ariz., is putting in a Jeanesville compound condensing station pump, also a large sinker in their mine.

THE Redfield Drill Co, 1606 Blake street, Denver, Colo., report receiving orders for one of their drills to be shipped to E. P. Baker, Laramie, Wyo., and one to W. L. Harraman, Alma, Colo. This company reports an increasing trade from all over the country.

THE Byron Jackson Machine Works of San Francisco, Cal., report shipping last week a 35 H. P. Olds crude oil engine and a 7-inch centrifugal pump to Guadalupe, Cal; also one 10-inch compound centrifugal pump direct-connected to 50 H. P. water wheel to Honolulu, H. I.

THE Pacific Gear & Tool Co of San Francisco, Cal., has moved its works from 523 to 529 Mission street, occupying the first floor and basement, gaining thereby greater space necessitated by the growing business, and the installment of several new and up-to-date machines for its special line of work.

Obituary.

T. C. MCGOVERN, a pioneer miner on the Comstock, died in Reno, Nev., June 24th. Deceased was a native of Canada, aged 58 years. He leaves a wife and three children.

Catalogues Received.

"Power Pumps" is the title of Catalogue No 52 of the Stilwell-Bierce & Smith-Valle Co. of Dayton, O. In it are described the pumps of various design manufactured by them. These pumps are particularly designed for heavy service, large capacity and high head "How We Heat and Purify Water for Steam Boilers" is the title of a supplementary catalogue issued by same firm, and treats of boiler waters, the correction of their impurities and heating for steam making.

New Patents.

DEWEY, STRONG & CO.'S SCIENTIFIC PRESS PATENT AGENCY, 330 Market St., S. F., has official reports of the following U. S. patents issued to Pacific coast inventors:

FOR WEEK ENDING JUNE 23, 1903.

731,651.—BICYCLE RACK—J. J. Allen, Portland, Or.
731,742.—WELL LINING—J. W. Beaumont, Los Angeles, Cal.
731,661.—DISTRIBUTING SYSTEM—F. C. Birch, S. F.
731,859.—TOOL—W. R Clark, Tehachapi, Cal.
731,875.—STEERING DEVICE—Elfler & Nauman, Oxnard, Cal.
731,569.—DRILLING MACHINE—J. G. Heimrich, Seattle, Wash.
731,570.—NOZZLE—G. J. Henry, Jr., S. F.
731,571.—TESTING APPARATUS—G. J. Henry, Jr., S. F.
731,681.—CANDY PULLING MACHINE—W. E. Henry, S. F.
731,777.—MATTRESS—J. Hoey, S. F.
731,465.—HARVESTER—F. L. Kincaid, Stockton, Cal.
731,918.—OIL TANK—G. B. Landers, Bakersfield, Cal.
731,793.—JAR CLOSURE J. A. Landsberger, Alameda, Cal.
731,590.—LEACHING ORES—C. W. Merrill, Alameda, Cal.
731,610.—FUMIGATING TENT—W. H. Payne, Monrovia, Cal.
732,628.—COMPOSITE BAR—R. H. Raphael, Los Angeles, Cal.
731,594.—TROLLEY FINDER—G. T. Roberts, San Diego, Cal.
731,628.—BRAKE—J. W. Spencer, Lagrande, Or.
731,631.—EXTRACTING GOLD—J. T. Terry, Jr., Altar Mex co
731,976.—DREDGER—Thunen & Cheshire, Oroville, Cal.
731,978.—JOURNAL BEARING—J Tobin, S F.
731,634.—ORE MILL—G. R. Tuttle, Grass Valley, Cal
731,641.—BABY JUMPER—G. W. Wheeler, Everett, Wash.
731,727.—ROCK DRILLS—W. W. Word, Soulsbyville, Cal.
731,728.—ROCK DRILLS—W. W. Word, Latrobe, Cal.

Notice of Recent Patents.

Among the patents recently obtained through Dewey, Strong & Co.'s SCIENTIFIC PRESS U. S and Foreign Patent Agency, the following are worthy of special mention:

BED OR COUCH MATTRESS.—No. 731,777. June 23, 1903. John Hoey, San Francisco, Cal. This invention is designed to produce a mattress of greater softness and durability than has hitherto been made, by preventing the slipping and matting of any of the materials of which the mattress is composed. The mattress is formed with a central body of laminated cotton or cotton felt and inclosing layers of silk floss at top and bottom, the structure being afterwards stitched and tufted.

CANDY PULLING MACHINE.—No. 731,681. June 23, 1903. Wm. E. Henry, San Francisco, Cal. The object of this invention is to provide a machine for rapidly and economically pulling candy so as to work it into the proper condition during its manufacture. It consists in a machine having parallel shafts with intermeshing gears, cranks upon the outer ends of the shafts and outwardly extending hooks or arms thereon, fixed supports or hangers exterior to said hooks with pins projecting into the space between the pair of revolving cranks, and means by which said intermediate pins may be adjusted up or down.

DISTRIBUTING SYSTEMS FOR LIQUIDS.—No. 731,661. June 23, 1903. F. C. Birch of San Francisco, Cal. One-half assigned to A. Lackman of same place. This inven ion relates to improvements in means for distributing liquids into tanks, vats and the like and to prevent loss by leakage or overflow by reason of the troughs becoming clogged. The tanks or reservoirs are arranged radially in nests, and the liquid pumped through mains and delivered by a peculiar valve mechanism into swiveled lateral discharge pipes, whereby each tank in a nest may be filled successively and whereby tanks in succeeding nests may be charged from the same main without interrupting the pumping operations.

Latest Market Reports.

SAN FRANCISCO, July 3, 1903.

METALS.

SILVER.—Per oz., Troy: London, 24½d (standard ounce, 925 fine); New York, bar silver, 52⅝c, refined (1000 fine); San Francisco, 52⅝c; Mexican dollars, 41c San Francisco, 41½c New York.

COPPER.—New York: Standard, $14.37½; Lake, 1 to 3 casks, $14.37½@14 62½; Electrolytic, 1 to 3 casks, $14.50@14 75; Casting, 1 to 3 casks, $14.00; San Francisco: $14 00. Mill copper plates, $17.00; bars, 18@24c. London: £57 10s spot per ton.

LEAD.—New York, $4 12½; Salt Lake City, $3.50; St. Louis, $4.00; San Francisco $4.50, carload lots; 4½c 1000 to 4000 lbs.; pipe 5½, sheet 6, bar 5½c; pig, $4.75. London: £11 16s 3d per long ton=2.75c per lb.

SPELTER.—New York, $6 25; St. Louis, $4.85; London, £20 5s 0d per ton; San Francisco, ton lots, 6½c: 100-lb lots, 7c.

ANTIMONY.—New York, Cookson's, 9¾c; Hallett's, 8½c; San Francisco, 1000-lb. lots, 10c; 300 to 500 lbs., 11c; 100-lb. lots, 13@15c.

TIN.—New York, pig, $28.12½@28 27½; San Francisco, ton lots, 29½c; 500 lbs., 30c; 200 lbs., 30½c; less, 31c; bar tin, ℔ lb, 32½c @35c. London, £127 5s spot.

PLATINUM.—San Francisco, crude, $18.00 ℔ oz.; New York, ingot, $19.00 per Troy oz. Platinum ware, 75@80c per gram.

QUICKSILVER.—New York, $44 50@46.00; large lots; London, £8 15s; San Francisco, local, $45.00 ℔ flask of 76½ lbs.; Denver, $49.50. Export, $43.50.

BABBITT METAL.—San Francisco, No. 1, 10c; No. 2, 7c; No. 3, 6½c; extra, 17½c; genuine, 35c; Eclipse, 37½c.

ALUMINUM.—New York, No. 1, 99% pure ingots, 35c; No. 2, 90%, 30c to 34c.

SOLDER.—Half-and-half, 100-lb. lots, 19½c; San Francisco, Plumbers', 100-lb. lots, 16c.

NICKEL.—New York, 50@60c ℔ lb.; ton lots, 45@48c.

STRUCTURAL MATERIALS.

IRON.—Pittsburg, Bessemer pig, $19.50@19 85; gray forge, $18 60; San Francisco, bar, 3c ℔ lb., 3½c in small quantities.

STEEL.—Bessemer billets, Pittsburg, $29 50@30 50; open hearth billets, $31.50; San Francisco, bar, 7c to 12c per lb.

LUMBER.—(Retail): Pine, ordinary sizes, $20.00@22.00; extra sizes higher; redwood, $22.00@23 00; lath, 4 feet, $4.25@4.50; pickets, $19.50; shingles, $2.35 for No. 1 and $2.00 for No. 2; shakes, $13.50 for split and $14.50 for sawed; rustic, $26.00@32.00.

NAILS.—Per keg (list prices): No. 20d to 60d, Wire, $3.25; Cut, $3.35; 10d to 16d, Wire, $3.35; Cut, $3.35; 8d, Wire, $3.40; Cut, $3.40; 6d and 7d, Wire, $3.50; Cut, $3.50; 4d and 5d, Wire, $3.60; Cut, $3.60; 3d, Wire, $3.75; Cut, $3.75; 2d, Wire, $4.00; Cut, $4.00. Special rates for carload lots.

LIME.—Santa Cruz, $2.25; Rocbe Harbor, $2.25 per bbl.

GENERAL SUPPLIES.

POWDER.—F. o. b. San Francisco: No. 1, 70% nitro-glycerine, per lb., in carload lots, 15½c; less than one ton, 17½c. No. 1*, 60%, carload lots, 13½c; less than one ton, 15½c. No. 1** 50%, carload lots, 11½c; less than one ton, 13½c. No. 2, 40%, carload lots, 10c; less than one ton, 12c. No. 2* 35%, carload lots, 9½c; less than one ton, 11½c. No. 2** 30% carload lots, 9c; less than one ton, 11c. Black blasting powder

in carload lots, minimum car 728 kegs, $1.50 per keg; less car lots, $2 per keg.

CAPS.—3x, $5.50 per 1000; 4x, $6.50; 5x, $8; Lion, $9, in lots not less than 1000.

FUSE.—Triple tape, $3.60 per 1000 feet; double tape, $3.00; single tape, $2.65; Hemp, $2.10; Cement No. 2, $3.00; Cement No. 1, $2.65, in lots of 3000 feet and up.

CANDLES.—Granite 6s, 16 oz., 40s., 10½c ℔ set; 14 oz., 40s., 9½c.

CHEMICALS.—Cyanide of potassium, 98%-99%, jobbing, 24@25c ℔ lb.; carloads, 23@24½c; in tins, 35c; soda ash, $2.00 ℔ 100 lbs.; hyposulphite of soda, 2½@2¾c ℔ lb.; caustic soda, in drums, 3@3½c ℔ lb; Cal. s. soda, bbls., $1.25@1.50 ℔ 100 lbs.; sks., $1.05; chlorate of potash, 12@13c; nitrate of potash, bbls., 10c; caustic potash, 10c in 40-lb tins; borax concentrated, 7@8c ℔ lb.; roll sulphur, 4@6c; powdered sulphur, 2@3c; flour sulphur, French, 2@3c; alum, $2.00@2.25; California refined, 2@2½c; sulphide of iron, 9c ℔ lb.; copper sulphate, 5@7c; chloride of lime, spot, $2.50@2.75; sulphuric acid, in carboys, 66% B, 2½c ℔ lb.; nitric acid, in carboys, 8c ℔ lb.

WHITE LEAD.—Per lb., in kegs: 500 lbs. and over at one purchase, per lb., 6c; less than 500 lbs., per lb., 6½c; in 25-lb. tin pails, ½c per lb. above keg price; in 1 and 5 lb. tin cans, 100 lbs. per case, ½c per lb. above keg price. Dry Lead—In bbls., 1 ton and over, 6c; do. in kegs, 6½c.

RED LEAD.—500 lbs. and over at one purchase, per lb., 6c; less than 500 lbs., 6½c.

LITHARGE.—Pure, in 25-lb. bags, 8@9c per lb.

BONE ASH.—Extra No. 1, 5@6c per lb. No. 1, 4@5c.

BORAX.—Concentrated, 7@9c per lb powdered, 9@12c; fused, 25@30c.

BORAX.—Crystal, 7c; calcined, 25c.

MANGANESE.—Pure, ℔ lb., 60c.

MOLYBDENUM.—$2 per lb.

CHROMIUM.—(90% and over) per lb., $1.00.

BISMUTH.—Subnitrate, per lb., $1.60.

SODIUM.—Metal, ℔ lb., $1.00.

MERCURY.—Bichloride, ℔ lb., 90c.

PHOSPHORUS. — (American) ℔ lb., 75c.

SILVER.—Chloride, ℔ oz., 90c@$1.00; nitrate, 55c.

ALUMINUM.—No. 1, 99%, small lots, 37c ℔ lb.; 100 lbs., 35c; 1000 lbs., 34c; ton lots and over, 33c, Pittsburg. No. 2, 90%, small lots, 34c; ton lots and over, 31c, Pittsburg.

URANIUM.—Oxide, ℔ lb., $3.50.

ZINC.—Metallic, chemically pure, ℔ lb., 50c; dust, ℔ lb., 10c; sulphate, ℔ lb., .04c.

COAL. — San Francisco, coast, yard prices: Wellington, $8.00; Seattle, $6.50; Coos Bay, $5.50; Southfield, $8.00. Cargo lots, Eastern and foreign: Wallsend, $6.50 Brymbo, $7.50; Pennsylvania, hd., $14.00 Scotch, $8; Cumberland, $12; Cannel, $9.00; Welsh Anthracite, $11.50; Rock Springs, $9.50, long ton; Colorado Anthracite, $14.00. Coke, $10.50 per ton in bulk, $13 in sacks; Sunnyside, $8.50, long ton.

(These prices are wholesale, f. o. b. San Francisco, unless otherwise noted.)

THE CALIFORNIA DEBRIS COMMISSION having received application to mine by hydraulic process from W. S. Kerr, in Old Stiff Gravel Mine, near Vallecita, Calaveras County, Cal., draining into Wades Gulch Creek which reaches Stanislaus River, gives notice that a meeting will be held at Room 96 Flood Building, San Francisco, Cal., July 20, 1903, at 1:30 P. M.

WANTED.

WANTED--MILL TAILINGS,

Gold, silver or lead, in New Mexico, Arizona or old Mexico. Will buy or lease. Give location, quantity and value. A. E. VAN VELSAN, Telluride, Colorado. Box 181.

GypsumWanted

I desire to learn of accessible tracts of land containing first-class gypsum deposits. Those near water transportation preferred.

T. B. JOSEPH,
405 Montgomery St., Room 6. San Francisco.

MINING STOCKS WANTED.

If you are a stockholder in any good going mining company and want to sell your shares

WE CAN GET YOU CASH.

Send for our price list of 500 stocks. It tells what we will buy and what we will sell.

CATLIN & POWELL, M 94, 35 WALL ST. NEW YORK.

SITUATIONS WANTED.

A YOUNG MAN WITH 12 YEARS' PRACTICAL mining experience wante position where the ability to do things and doing them will lead to advancement. Can aesay, survey, run engine or pumps, sharpen toole, or do anything ahout a mine. Have some mill experience. References given. Address R. J. S., care of this office.

ASSAYER AND CYANIDE MILLMAN DEsires position. References. Address "Aesayer," care of Mining and Scientific Press.

CAPABLE ENGINEER OF GOOD STANDING and experience would like to purchase an interest in an established engineering husiness—mining or civil. Only a husiness capahle of expansion and doing high grade work is desired. Address "Experience," care of Mining and Scientific Press.

EXPERIENCED ANALYTICAL CHEMIST. ASsayer and Millman desires position. Address H. T. S., thie office.

FIRST-CLASS METALLURGICAL CHEMIST and Assayer desires position. Can furnish hest of reference, etc. Address C. W. L., this office.

FIRST-CLASS MINING AND LAND SURveyor, Draughtsman, etc., desiree position. Address H. W K., Box 74, Long Beach, Wash.

MECHANICAL ENGINEER—HAVE A UNIversity education and am an all around practical mechanic. Four years experience in steam and hydraulic engineering; have designed an up-to-date hlast furnace; have heen connected with large copper mine for two years: good references. Prefer large gold or copper mine; foreign country preferred. Address A. B. C., care Min. & Sci. Press.

MINE SUPERINTENDENT WANTS POSITION with a suhstantial company that has a mill on property. A qualified mining engineer who can run a mine or mill, cyanide plant, asseying and surveying. Address "Mining," this office.

MINING MAN OF 14 YEARS' EXPERIENCE. Thoroughly familiar with modern mining methods. Expert mill. cyanide and chlorination man. References. Address B, this office.

MINING ENGINEER, 26, GRADUATE MINING Department University of California; for pest thirteen months employed hy one of largest mines in Mexico as head assayer and chemist, also mill assietant; after took cherge of 60-stemp mill and hacienda. Has had some experience in mining, cyaniding, surveying, drafting, and good experience in pan amalgamation. Best of references from hoth general manager and superintendent where last employed. Address 1666 Page St., San Francisco.

HELP WANTED.

WANTED--An Experienced General Superintendent and Foreman for Large Construction Contract Near City.

Must he a man of vast experience and great ability, and one thoroughly able to handle men to the hest advantage; familierity with timher and concrete work neceeesry; hest references will he required; high salary to the right man. Box 39, this office.

ASSESSMENT NOTICES.

MARINA MARSICANO GOLD MINING COMpany.—Location of principal place of hneinece, San Francieco, California; location of worke, Sunny Hill, Shaeta County, California.

Notice is hereby given, that at a meeting of the Board of Directore, held on the 4th day of June, 1903, an aeeeeement (No. 26) of ten ecente per share wae levied upon the capital stock of the corporation, payahle immediately in United Statee gold coin to the eecretary, at the office of the company, 415 Front street, San Francieco, California.

Any etock upon which thie aeeeesment ehall remain unpaid on the 1et day of Auguet, 1903, will he delinquent, and advertieed for eale at public auction; and unless payment ie made hefore, will he eold on MONDAY, the 31et day of August, 1903, to pay the delinquent aeeeeement, together with the coete of advertieing and expeneee of eale.

By order of the Board of Directore.

CHAS. BOVONE, Secretary.

Office—415 Front etreet, San Francieco, California.

EUREKA CONSOLIDATED DRIFT MINING Company.—Lccation of principal place of husiness, San Francisco, California; location of works, Placer County, California.

Notice is herehy given, that at a meeting of the Board of Directors, held on the 15th day of May, 1903, an assesement (No. 37) of one-half (½) cent per share was levied upon the capital stock of the corporation, payahle immediately in United Statee gold coin to the secretary, at the office of the company, 214 Pine street, San Francisco, California.

Any stock upon which thie asecssment shall remain unpaid on the 20th day of June, 1903, will he delinquent and advertieed for eale at puhlic auction; and unless payment is made hefore, will he eold on SATURDAY, the 11th day of July, 1903, to pay the delinquent aeeeesment, together with the coste of advertieing and expenneee of eale.

By order of the Board of Directors.

GEO. W. DIXON Secretary.

Office—Room 31, 214 Pine street, San Francieco, California.

POSTPONEMENT.

The date of the delinquency of the foregoing aseeesment (No. 37) hae been postponed to SATURDAY, the 11th day of July, 1903, and the day of sale from the 11th day of July, 1903, to TUESDAY, the 28th day of July, 1903. By order of the Board of Directors.

Have You Decided to Adopt That Treatment for Your Ore?

Are you sure it will suit? Regrets will not change the machinery after the thing is done. Let us take the responsibility and select, install and put plant in operation under guarantee. Come and have a talk with us about it anyway—or write us. If your present plant don't do the work, let us prescribe for it.

MINES EQUIPMENT COMPANY,
CONTRACTING AND CONSULTING ENGINEERS,
306 PINE STREET, SAN FRANCISCO, CAL.

[ELATERITE IS MINERAL RUBBER.]

YOU MAY INTEND BUILDING or find it necessary to REPLACE A WORN-OUT ROOF.

ELATERITE ROOFING

Takes the place of shingles, tin, iron, tar and gravel, and all prepared roofings. For flat and steep surfaces, gutters, valleys, etc. Easy to lay. Tempered for all climates. Reasonable in cost. Sold on merit. Guaranteed. It will pay to ask for prices and information.

THE ELATERITE ROOFING CO.,
713 Market Street, San Francisco.

SPADONE'S CONCENTRATOR BELTS.

PATENTED.

Thie illustration ehowe the edge flanging outwardly ae it passee over the pulley. Thie relievee the etrain from the top and hottom of the edge hy directing the etrain automatically to the inside face eurface of the edges. Heretofore all helts have heen eo constructed that when they pass over the pulleys or rolle, a direct etrain comes upon the top or at the hase of the edges, causing the edges to hreak away from the hody of the helte in a very short time. *We avoid this Mechanical Defect by our Spadone Curved Edge.* Belte made to fit any machine—4, 5 and 6 feet wide. Prioes and samplee on application.

AMALGAM PLATE CLEANERS.

Our Amalgam Plate Cleanere are made of Pure Ruhher in moulds, thus insuring a plate cleaner which will not ecratch the plates and a perfect edge which will clean the Amalgam plates evenly. They are made 6 inches long, 3 inchee wide and ⅛ inch thick, making a convenient eize to handle. Prioe hy mail to any address, each 75 cents. Correspondence solicited.

Send ne yonr order for Water, Air Drill, Steam, Snction and Fire HOSE, RUBBER BELTING, RUBBER PACKING and LEATHER BELTING.

THE GUTTA PERCHA RUBBER AND MFG. CO.,
26 FREMONT STREET, Telephone Main 1813. SAN FRANCISCO, CAL.

ESTABLISHED 1859.

Hand-Power Mining Pumps.

60,000 Sold in 14 Years.

CAPACITY No. 8—4000 gallons per hour.
No. 10—6000 gallons per hour.

USED BY Calumet & Hecla Mining Co. Temple Iron Works.
Boston & Montana Mining Co. De Beers Mines, South Africa.

Send for Guarantee Trial Offer and Special Mining Catalogue C.

Head Frame Construction.

The designing and construction of head frames under peculiar and unusual conditions is of frequent occurrence. It is not always an easy or inexpensive matter to huild a head frame in such a manner as to make suhsequent operations as economical as possihle. Of course, this is usually due to the relative position of the mine shaft and the mill. Not infrequently a head frame must he built on a substructure of piers or posts, which rest on walls or sills of wood in order to secure dumping room. This occurs when the shaft is sunk on a flat. In case this is not done, then the material hoisted, ore or waste, must he elevated some distance ahove the collar of the shaft and trammed on an elevated trestle to the dump. In other instances the location of the shaft in the hottom of a gulch having steep slopes, or on the side of a steep hill, necessitates the exercise of no little ingenuity in design and construction. The shaft may he placed arhitrarily with reference to certain underground development previously performed, and the hoisting engine must be located in such a manner that the expense of hoisting shall be as low as possihle. In all of these calculations the head frame is an important factor. The accompanying engraving illustrates in a striking manner the ahove statements. It is a view of the incline and trestle at shaft No. 5 of the Congress mine at Congress, Arizona. The sheave wheel is 75 feet ahove the ground. The posts of the suhstructure are 10x10 inches, carefully framed and hraced. Ahove this is the head frame proper, the main memhers of which are of 12x12-inch timhers. A douhle hin with swinging apron, situated in the frame, receives the ore from self-dumping skips of peculiar construction, one of which may he noticed on the incline. The ore or waste is drawn from its separate compartment in the bin into cars. Waste is trammed about 100 feet and dumped; the ore is trammed over the storage hin and any waste present sorted out on the floor across the bin caps. Local conditions prevent the use of chutes direct from the skip. The ore hin holds 250 tons and delivers 125 tons at a trip to the railroad cars for transportation to the mill. The skip holds one and one-half ton. No. 5 shaft is down 1200 feet, and sinking is still in progress. The head frame here described and illustrated was constructed in July, 1902. It is a most ingenious construction, and has overcome the difficulties which the topography of the country placed in the way of ordinary huilding. The ohject in building the frame so high in this instance was to get dumping room for waste and at the same time to make it convenient to fill the railroad bin hy gravity. On page 22 is an illustration of another head frame at shaft No. 4 of the Congress mine. This frame is somewhat similar to that at shaft No. 5, hut is much more simple. There are no posts in a vertical plane except the hin posts, and no outside hraces as such. The sheave is 28 feet above the sill. The bins are of the same height as those in No. 5 frame. The skip shown holds one ton of ore, but the dumping compartment accommodates two tons. All timhers in this frame are 8x10 inches, except two main posts, which are 10x10. As compared with the usual frame of two vertical posts, with cap and hraces, a head frame of the ahove type of construction is more economical, in timber and lahor, while securing greater rigidity, and requires less ground space. An apron is provided at the hack of the shaft, which when desirahle may he lowered and the rock skip run hack on the track shown, and a water skip suhstituted for it. The gates of the ore hins are provided with direct acting levers in place of the rack and pinion so commonly seen. A careful study of the design of this frame will repay all who are interested in head frame construction, as it emhodies engineering features not commonly ohserved in frames of the rectangular type, or in tapering frames with four posts.

Incline and Head Frame at Shaft No. 5, Congress Mine, Congress, Arizona.

There is a tendency on the part of those designing head frames, who are not technically educated mechanical engineers, to put much more timher into a head frame than is really necessary. Some of these frames cost 100% to 300% more than is actually required. Western miners generally would he surprised to see some of the frames huilt over shafts in the lead and zinc regions of Missouri. Some of these frames have a rectangular or square hase, tapering somewhat toward the top and are constructed of lumher —not of timhers 10x10 or larger. In some of these frames there is not a piece of lumher larger than a 2x8-inch stick.

A Duty on Nitro Powder.

The recent imposition of a tax on nitro powder hy the Republic of Mexico seems to have heen anticipated hy mine managers and dealers in mining supplies. The law hecame operative about July 1, but previous to that date a very large amount of powder was shipped into the country, enough to last for many months, it is said, in view of the tax, which amounts to ahout 4.5 cents per pound, a duty of nearly 45% on first cost of consumer hy the carload in the United States. It is said the Mexican Government has given a concession to certain persons for the exclusive privilege to manufacture nitro powder in the Republic. What the outcome will he is uncertain. It is not helieved, however, that the new concern can operate successfully without this high protective tariff. A large increase in the cost of an article so essential to economic mining as nitro powder has hecome, cannot hut have a depressing effect on the development of Mexico's mineral resources, particularly in that of low-grade mines, which in Mexico, as elsewhere, are run on a close margin. The manufacture of nitro powder is a business requiring high technical skill, years of experience and the most careful manipulation. Where all of these prerequisites are not ohtainahle, and sometimes where they are, the result is not always satisfactory, and in the former case often disastrous, as the repeated destruction of powder manufacturing plants in the United States proves.

IT is stated that if eight companies operating on the Rand, in South Africa, were to suhstitute white lahor for hlack on the hasis that the lahor of one white man equals that of two hlacks, the natives receiving 2 shillings 4.2 pence per day and the whites 12 shillings per day, the excess in cost per ton would exceed $2.50. This is a very suhstantial argument in favor of native lahor. The problem of lahor on the Rand seems to he likely to find a solution in the failure to a great extent of the native meelie crop in Natal, this misfortune having the effect of causing the natives to seek work in the mines of the Transvaal.

The Copper Outlook.

The price of copper is slowly going down, and those interested in the industry, either as producers, consumers or dealers, are watching the market with much interest, if not anxiety. It is thought hy some who are in a position to know the real condition of things, and who are as thoroughly informed as to supply and demand as modern means of information will admit, that the present lowering price is only temporary. Large consumers have not yet made their annual contracts, and are said to he stock taking at the present time. This done, extensive orders are expected, which will stimulate the price, and a recovery to 15-cent copper is anticipated in consequence. The optimistic ones also say that the shutting off of production of about 20,000,000 pounds of the Anaconda, Mont., output, necessitated by the shut-down of those works for several months during summer, to enable them to make improvements in the reduction plant, will have a tendency to aid the market. It is contended that none of the large producers have any considerahle amount of metal on hand. The export trade, however, has fallen off considerahly, and prices in Europe are relatively lower than in New York.

Copper has had a very favorahle year, and the high market price, together with cheapening of cost of production in many districts, has had the effect of stimulating production in a marked degree. The demand for copper has apparently kept pace with the production, however, and there is no immediate indication that there will he a material decrease in the requirement of copper. Throughout the industrial world there is a demand for cheaper power, no matter what the price may have previously heen. In many instances this demand is met hy electric installation which calls for large amounts of copper.

A great deal has heen published of late concerning the copper resources in the Katanga district, in the southeast end of the Congo State, Central Africa. The property is known as the Tanganiyka concessions. The statement that there are already in sight in one of the company's claims 10,000,000 tons of copper ore should he taken with some allowance, though douhtless the mines look promising. Every explorer who has penetrated into the heart of Africa reports copper on the upper Congo and its southern affluents. The Tanganiyka concessions are in this district, lying north of Rhodesia and west of Lake Tanganiyka, one of the sources of the Congo river. For many generations the natives have worked the iron and copper deposits in that region, and it is stated that the large deposit ahove referred to is already honeycomhed with the workings made hy the natives. In addition to this, it is said that there are numerous other copper-hearing deposits in that region. Whatever may be the future of the Tanganiyka concessions, it is unlikely that they will hecome an important factor in the copper world within three years, and it may be still longer, for railroads must he huilt, power controlled, reduction works constructed and many other things accomplished, all of which take time in any country, and it is not to he expected that this large amount of preliminary work can or will be more quickly accomplished in Equatorial Africa than elsewhere.

A railroad is projected into the Katanga region from the west, which will he not less than 900 miles in length. The Congo as a waterway would he the natural outlet, hut the streams in the vicinity of the mines are for the most part unnavigahle. On the main Congo the Stanley Falls form another ohstruction, extending for miles in a series of great falls and cataracts.

A Uniform Signal Code Needed.

A uniform code of mine-hell signals is much to he desired, for the reason that miners are, as a class, migratory, seldom remaining in one locality for any considerahle length of time. After having worked in a district for some months he hecomes thoroughly familiar with the code in use there, but upon removing to another State or district he must, in many cases, learn anew the code of that State or locality, and although this may he mastered readily enough, such a man is at any time liahle to meet accident or cause injury to others by inadvertently ringing a signal previously familiar to him, hut which may mean something entirely different in the new locality in which he is working. Fortunately steps are heing taken to harmonize the conflicting codes of the several States and localities. This matter should he taken up hy the American Institute of Mining Engineers and other mining societies and conventions, when a suitahle code would prohahly result, which would he found applicahle to mines of every class, and in every State or district.

Measurement of Undeveloped Ore.

An ore hody not hlocked out hy actual shafts, drifts, crosscuts, winzes and raises is a most uncertain quantity. The trend of the walls forms no index of the quantity of ore not actually measurahle. An ore body is seldom symmetrical in form, and the shape or dimensions of any one portion of it cannot he depended upon to give even an approximate idea of the extent or value of unseen portions of the same ore hody. Good hodies of ore disappear or come to an end in the most unaccountahle manner. Crossheads or faults cut off veins regular and apparently continuous. Mineralization sometimes stops at a jointing plane, and values hecome impoverished or nil. In other instances the mineralization continues, hut values cease to accompany the ores or drop to a point where profit is no longer possihle. The engineer who not long since said "the average mining report is only a nice fairy tale" was not far from the truth, for there are those making reports on mines in these days of prosperity whose entire mining knowledge and experience has heen gained within a year. The man who wrote in a prospectus that the ore shoot had heen developed 300 feet in length and the shape of the hill indicated that it would he at least 300 feet longer was certainly favored with a "gift" not possessed hy most people—that of seeing several hundred feet into the undeveloped portion of a mining claim. He was frank enough, however, not to include this extension of the vein in his estimate of "ore in sight." A prospect may he poor indeed, hut any prospect deserves a trial; and if an improvement can he noticed, it is safe to follow it as long as it improves, for hefore long it will have developed a paying mine. But this simple fact does not justify misstatements as to ore in sight, nor does any numher of years of experience make a man competent to estimate ore in sight in undeveloped mine workings.

Steel vs. Timber Head Frames.

On the Rand, South Africa, steel head frames are displacing the old timher frames, and new mines are being equipped with steel frames as soon as the permanent plant for deep working is estahlished. In the United States and Mexico a somewhat similar condition is noticeahle, particularly in those districts where suitable timher is scarce and expensive. The weight of a steel frame varies greatly according to design and size, hut usually runs from 25 to over 100 tons. A large and elahorate frame will weigh more than 100 tons. Timher frames are subject to decay, and deterioration otherwise in the course of a few years, and are always menaced by fire, though care is used to prevent such a catastrophe. On the whole, a steel frame is superior in many respects, and it will prohahly be hut a few years when steel frames will be almost as common as timber frames are now. They can he taken down and removed to a new site without damage or loss if properly designed and constructed. Steel frames are in use at some of the deepest shafts in the world. Timber frames are also in use at shafts of great depth—2000 to 3000 feet and over—so from that standpoint it may be said there is no particular advantage to either over the other, hut the reasons already given will eventually make the steel head frame preferred to timher frames.

MANY prospectors lay great stress upon the character of the country rock through which their veins run. As a matter of fact the kind of rock is of small consequence. If the ore in the vein has little or no value, the "kind of rock" through which the vein runs will make no material difference to him. The "character" of the rock rather than the "kind" sometimes affords an indication of the proximity or ahsence of ore hodies, hut not of the value of the ore.

CONCENTRATES.

IN some classes of work spring steel, tempered in oil' it has been found, will draw its own temper by removing the steel from the oil, while still retaining heat.

SYLVITE contains no silver. It is a combination of chlorine, 47.6, and potassium, 52 4, forming potassium chloride; sometimes contains sodium chloride. Sylvanite is a telluride of gold and silver and contains 24.5% gold and 13 4% silver.

DIAMOND DRILLS are made to be operated by hand power, claimed to have a capacity of 300 feet, boring in any direction. It is probable that a drill operated by power would prove more satisfactory in the end, though the first cost would be more.

STADIA MEASUREMENTS may be carried on with a good transit with sufficient accuracy up to 600 feet, and with very high powers somewhat further, but when exceeding 1000 feet the results are sometimes unreliable, excepting possibly under very favorable conditions.

AMETHYST is a purple-colored quartz crystal, in which the color is supposed to be due to manganese. Oriental amethyst is a purple variety of sapphire. It is a peculiar variety of that gem, having a stellate opalescence when viewed in the direction of its vertical axis.

THE fact that a man is an excellent and experienced blacksmith, and is able to fashion and temper drill bits to a nicety, does not necessarily imply that he is a machinist, competent to care for a machine drill. Many drills are ruined through the incompetency of the "machinist."

STEEL is largely employed in construction of mill, smelter and other reduction plants. It is customary to carefully paint all structural steel, and a suitable paint renders the steel impervious to acid fumes and gases, as well as to dampness due to steam or natural humidity of the atmosphere.

THE aggregate power of a fall of water is the product of the weight of water discharged in a unit of time into the total head. The term "head," used in connection with water power, means the difference in height from the surface of the water in the wheel pit to the surface of the water in the penstock when the wheel is running.

A MACHINE DRILL too much worn to be economically valuable in a mine may be fixed up and mounted on timbers on the surface to be employed as an engine for pulverizing samples of rock. One accustomed to its use can pulverize fifty to sixty two-pound samples daily to a condition requiring little grinding on the bucking board.

A MILLING PRACTICE which does not make a satisfactory saving of values should be abandoned, even if it has been in use for over thirty years. It is possible the ore may have changed in character with increasing depth of the mine. This is usually the case, and when this occurs the milling practice must necessarily undergo more or less change.

SULPHUR occurs in iron ores as sulphides, such as pyrite, and in sphalerite (zinc blende), also as sulphate in gypsum, barite and celestite. In iron and steel it occurs as sulphide only. In the gravimetric methods for determination of sulphur it is first converted into a soluble sulphate and the sulphuric acid precipitated by barium chloride and weighed as barium sulphate.

THE "angle of convenience" is the slope angle assumed by loose rock, as that collected at the foot of a precipice or the front of a mine dump. This angle varies slightly with different materials, but is about 35°. Few hills are steeper than 35°, though often appearing to be steeper. The character and dip of the rocks often have important bearing on the slope angle of a hill.

"BLOWING-IN" in blast-furnace parlance means the beginning of smelting operations in a new furnace, or in an old one after a period of idleness. It consists of three operations: Warming the crucible, filling the furnace and beginning the smelting. The process is one requiring good judgment and experience. It should never be hastily undertaken, as by raising the heat too rapidly damage may result to the furnace.

IRON PSEUDOMORPH after garnet may occur, but it is more probable that the crystals of iron ore, said to be pseudomorph after garnet, are only natural forms of pyrite, or of limonite after pyrite. Garnet and pyrite each crystallize in the same system—the isometric, and some of the forms bear a great similarity to each other, and one might easily be mistaken for the other by those not thoroughly familiar with crystallography.

IN cyaniding, the once dreaded slimes are in some localities now created intentionally, for the reason that it has been found that much higher extraction can be generally obtained than when the ore under treatment is not in a fine state of division. In treatment of slimes the filter press is an important factor, though large amounts of slimes are treated by decantation. This has been accomplished successfully on clayey and talcose ores.

OIL WELLS are sometimes drilled under the direction of those having no knowledge of geology, in rocks containing no oil, being hard, crystalline schists, and in which any one acquainted with rocks, or having only elementary knowledge of geology would know that no oil need be expected. Those contemplating the sinking of prospecting oil wells should seek competent advice before undertaking this expense, if not well acquainted with oil-bearing formations.

IN the manufacture of glass, sands of varying kinds are used for the several sorts of glass. Clean sand free from iron is used in making ordinary window glass, but flint is necessary for the whiter and clearer varieties. For bottle glass, such as seen in the green variety, any sand is suitable. Granulite, a micaless variety of granite, is used extensively in glass manufacture, as it naturally contains the necessary ingredients. Moulder's sand has sufficient clay to keep the moulded form.

NITRIC ACID is manufactured by heating a mixture of potassium or sodium nitrate and sulphuric acid, and condensing the acid vapors in a cooled receiver. Acid thus formed contains water derived from that in the sulphuric acid, and also in part from that derived from the decomposition of a portion of the nitric acid by heat. The acid is purified by mixing it with an equal portion of sulphuric acid and redistilled. The distillate is warmed and a current of dry air passed through it to remove nitrogen tetroxide.

CHLORITE is a green iron-magnesian silicate of aluminum with chemically combined water and no alkalies, and is the result of alteration of hornblende, pyroxene, biotite, etc. Chlorite schist is a granular to schistose aggregate of scaly chlorite with quartz grains. It is sometimes accompanied by feldspar, talc, mica, epidote and magnetite. It results from the alteration of greenstones. Chlorite schist is not infrequently gold-bearing, and in some regions large masses are mined and milled at a profit. The rock is usually green, but it is sometimes red, or grayish green.

IN SINKING SHAFTS, particularly inclines, there is little, if any, economy in making the compartments so small that men cannot work freely. An incline having an inclination of 70° should measure at least 4.5 feet from foot wall to hanging wall plate, and if of less than 70° should have not less than 5 feet clear. A good roomy shaft not only becomes safer for the men, but it also makes it possible to hoist a large tonnage should it ever become necessary to do so. The difference in the cost of a large and a small shaft of the same number of compartments is not great, and will usually pay for the additional investment.

PLATINUM is a dense metal of tin-white color, moderately hard, and ranks next to gold and silver in malleability and ductility. It is readily drawn into fine wire and rolled into thin sheets. It is infusible in the ordinary wind furnace and in the flame of the Bunsen burner; but very fine platinum wires may be fused in the flame of the blow-pipe. It is not attacked by any single acid. Liquids containing free chlorine will slowly dissolve the metal. An alloy consisting of platinum and iridium is harder and not so readily attacked by acids as pure platinum, and this alloy is commonly used in the various platinum utensils employed in chemical laboratories.

THE term "mineral zone" as used in contradistinction to a "mineral vein," refers to the fact that a mineral zone is not always clearly defined, as by walls. The mineralization may extend along one or both sides of a fissure having no defining limits, while a vein is presumed to be situated wholly within definite bounding planes and may be easily distinguished from the adjoining country rock. In a zone of mineralization the mineralization may gradually disappear as distance from a central crack or fissure increases until it ceases altogether. A mass of rock within which occurs several veins or ore bodies is also often referred to as a zone.

THAT there is any economy in feeding stamp batteries by hand it would be difficult to prove to a mill man of modern ideas. Hand feeding went "out of style" twenty-five or more years ago, though there are a few isolated localities where it is still practiced. A man who feeds a battery by hand for $1 a day and his board, costs at the end of a year at least $500. This sum will buy six first-class automatic ore feeders, which will feed six batteries of five stamps each, whereas three men would be required to feed this number of stamps at each shift. Comment of the saving effected, to say nothing of the better feeding, is unnecessary.

IT is not to be expected that an ore containing 10% to 15% sulphides, with gold in a very fine state of division, would be treated in the same manner as an ore containing but 1% or 2% sulphides, with a large percentage of gold free in the gangue. These two conditions in the character of the two ores practically represent the difference between the treatment of gold ores in Gilpin county, Colo., and in Amador or Calaveras counties, Cal. The former is slow and difficult to amalgamate, and explains why the high slow-speed drop is employed, and the latter instance indicates the advisability of employing the short quick-drop, the common practice in California. A slow-drop Colorado mill was built on a sulphide mine in eastern San Bernardino county, Cal., in 1892, but did not accomplish satisfactory work. This may have been due to the mill work, rather than to the mill.

ARTIFICIAL DIAMONDS of microscopic size have been produced recently in an electric furnace by fusing iron rods and carbon at a temperature of 3500° C. and plunging the crucible containing the melted iron into a bath of molten lead. The iron breaks into fragments, and being lighter than the lead rises to the surface of the bath in spheroidal forms. Within these spheres are found the microscopic diamonds, some black (bort), others bright, clear and sparkling, some colorless, others yellow, etc. In fact these minute diamonds appear to possess many, if not all, of the physical characteristics of the larger diamonds found in the South African mines. Strangely, however, the artificial stones split after a few months exposure to the atmosphere, though a similar phenomenon has been occasionally observed in diamonds weighing a carat or more, taken from the blue ground of De Beers and Kimberly mines.

A GOOD METHOD of dispelling foul air from a tunnel after a shot is in use by W. M. Bainbridge at the El Paso mine, Cripple Creek district, Colo. A steam pipe is connected with the air line with a valve close to the connection. After shooting, the air is turned off and the steam is turned into the breast of the drift for ten minutes. Then the steam is turned off and the air turned on. The steam absorbs the poisonous fumes in the smoke. The air cools the drift. One half to three-quarters of an hour is saved in time. The blowing of steam into a drift or shaft after blasting will hasten the clearing up of the smoke and gas, whether compressed air be available or not. This practice is detrimental to timbers. However, the damage done to timbers, causing expense in replacing them with new ones, is more than offset by the small loss of time with which men can resume work after blasting.

MACHINE ROCK DRILLS are not a new institution in mining. The first rock drill was put into practical service in the United States in 1838. The first type of rock drill was known as the "drop drill," by reason of the drill bar and bit being lifted by a cam, or crank, and allowed to fall, in the same manner as a mill stamp. Springs were also introduced to accelerate the speed or force of the downward blow, and the elasticity of the air was in some instances employed for this purpose. These machines were first employed upon open canal or quarry work. The first drill which at all resembled, even in a small degree, the modern air or steam drill, was made in 1848. In this machine the drill was operated by steam, the drill bar passing through the piston. It was alternately drawn back and plunged forward against the rock. This drill was not a success, being too cumbersome and expensive to operate, but it was the first step toward the type of machines now in successful use everywhere. A German engineer named Sommeiller was the first to run a machine drill with compressed air, at the Mt. Cenis tunnel, driven through the Alps mountains. The term "Burleigh drill," now applied almost without discrimination to any make of machine drill, is due to the fact that the Burleigh machine was one of the first in practical use, though it was preceded by the Hanson, Brooks and other drills.

THE hydrographer in charge of the United States Survey at Yuma, Ariz., reports that 75,000 cubic feet of water per second is flowing past Yuma in the Colorado river at present, and that the river is unusually high. In midsummer this river is always higher than during other seasons of the year, owing to the melting snows on the high ranges of Colorado and Wyoming, the western drainage of which flows into the tributaries of the Colorado. The vast volume of water flowing past Yuma receives no material addition at any point between Yuma and the San Juan river, in southern Utah. When the river is high it usually overflows into the great depression in southern California known as Salton basin. This basin is about 140 miles in length by about 30 miles in average width, and covers approximately 4000 square miles. At the lowest portion of the basin it is 265 feet below the level of the sea. The ancient shore line can be plainly seen around the greater portion of the basin, the average depth of which below the level of the Colorado river is probably about 100 feet. At one time in the past—but, geologically speaking, at a very recent date—this basin was an estuary or arm of the Gulf of California. The Colorado, which, like all rivers carrying a large amount of sediment, gradually built up bars along its banks and eventually cut off the connection of the interior basin with the gulf, and in succeeding years the basin gradually dried up by evaporation and absorption, until nothing was left of the once great body of water but a salt marsh at Salton. In 1892 the river overflowed, making extensive breaches in the natural levee it had itself constructed. As the river went down, however, this inflow stopped, and since that date no overflow of consequence has been reported. Should the great volume of the Colorado, however, be turned from its present course into the Salton basin, it would probaby require not less than seven years of continuous, uninterrupted flow at the rate of 50,000 cubic feet per second, which is considerably above its average amount of flow, to fill it. This estimate takes no account of absorption or evaporation, which would be excessive.

Dredging and Valuing Dredging Ground in Oroville, Cal.*

Written by NEWTON BOOTH KNOX.

The gravelly bottom land below Oroville, Cal., is being extensively mined for gold by means of dredgers. Upon a strip of land 9 miles long by 2 miles in width, bordering on and adjacent to the Feather river, twenty-one dredgers are at present working. These dredgers are the property of about twelve companies, who own dredging land varying from 80 to 800 acres. The companies are all close corporations, and though the official figures of working costs and profits are difficult to obtain, it is well known that they yield their stockholders excellent dividends. For instance, one company's working expenses, including labor, repairs, power, interest on capital invested, depreciation of plant, sinking fund, etc., amounted to but 32% of the bullion output, leaving the remaining 68% clear profit.

The total general average of the drillings of several of the largest companies' holdings, covering a period of several years, gives the value of the gravel between 17 cents and 19 cents per cubic yard, and average depth of 11 yards. As a dredger handles from 1200 to 2000 cubic yards per day, at a cost of from 5 cents to 8 cents—average 6 cents—per cubic yard, it is evident that the returns in this work are considerable.

HISTORY.—In the early days of California history Oroville district was extensively mined by first the white man and later by the Chinese. It is claimed that $82,000,000 has been taken out within a radius of 8 miles of the town of Oroville. The gravels were worked to water level, and washed mostly in hand rockers. Pits and small shafts were sunk until a rich paystreak was encountered, which was followed, drifted out, hoisted to the surface and rocked. Water interfered greatly with this style of mining, and only the richest streaks could be worked. The gravels left made excellent dredging ground.

THE GRAVELS.—The gravel deposit about Oroville evidently represents the flood plain of an ancient stream of the Sierra Nevada, near the point where it debouched into the gulf which then occupied the present great valley of California. As stated, the gravels average about 33 feet, varying from 28 feet to 60 feet in depth. A false bedrock of lava ash, or volcanic tufa, varying from the consistency of chalk to that of firm sandstone, is encountered at this depth. Below this false bedrock are gravels and sand. In one place a hole was drilled 80 feet below, and showed sharp white sand. In some places the gravel is topped by a red soil overburden, varying from 10 feet to 25 feet in thickness. This overburden and the material below the false bedrock contain little or no gold. The gravel is fairly coarse, large boulders—weighing 300 pounds or 400 pounds—being very exceptional. One-half of the gravel will pass through a ½-inch screen. As a rule the gravel is not cemented, though some dredgers have encountered pieces of ground which had to be loosened with powder.

The gold is distributed more or less equally throughout the gravels. Rich concentrated streaks of from 1 inch to 1 foot in thickness occur, followed by barren sandy areas, which seem to represent varying conditions of flow in the depositing stream. The gold is in a very finely divided state, and easily caught by the riffles, cocoa matting and quicksilver of the dredger. Nuggets are a rare occurrence. The gold found in the boreholes is 922 fine and worth $19 an ounce. The dredger bullion is somewhat lower grade, the base being the surprisingly large amounts of lead in the form of quail, rabbit and duck shot which the dredger digs up.

This fact is interesting and would be hard to believe if it were not very well authenticated. This region has been a great small game country, and during the last fifty years doubtless thousands of pounds of shot have been scattered over the gravels which the dredger is now recovering. Nor does it require such reckless shooting on the part of these old hunters to reduce the bullion grade as would at first appear. Take an 11-yard bank of gravel. This contains 50,000 cubic yards to the acre. A dredger could treat an acre of this a month, producing a bar per month of say $10,000, or, roughly, 500 ounces of bullion.

Now, if the bullion from drillings went $19 = 950 fine, all gold, and if the bullion from the dredger went $17 = 850 fine, all gold, or 50 ounces gained in lead in the 500-ounce bar, fifty ordinary shotguns, 12 gauge, would furnish this much shot. The baseness of the bullion, however, does not truthfully represent the amount of shot, as on most of the dredgers the lead is separated by panning, and carefully picked, before the bullion is melted. On the Butte dredger they have collected about 50 pounds of shot from about 2 acres of gravel.

Occasionally a pistol ball is found, recalling the golden, glorious old days of California history, when some festive "man behind the gun," filled with enthusiasm and "harb wire" whisky, would sally forth in search of trouble and—generally find it.

The Oroville district is peculiarly favorable for dredging, for the following reasons:

1. Bedrock (so called) is soft and easily cut by the dredger.
2. Boulders are small.
3. Water is available.
4. Power (electric) is cheap.
5. Gold is fairly evenly distributed.
6. Climate is such that work can be carried on twelve months of the year.
7. Labor is cheap and efficient, and, finally,
8. The gravel contains enough gold.

TESTING THE GROUND.—In order to ascertain whether a piece of ground is worthy of consideration, the following system is adopted:

The land is first divided, according to its area, into blocks of from 5 to 10 acres, and a hole is drilled in the center of each of these blocks.

The driller generally adopted in Oroville consists of a "walking beam" operated by steam power producing the required motion for raising and dropping the drill. In addition to this is a reel, on which is wound the rope of the sand pump used in pumping out the holes. The drill is suspended by a 2-inch Manila rope, which passes under one sheave on the walking beam over another to the main drum. As the walking beam moves, the rope is alternately tightened and loosened, which raises and drops the drill. The drill itself consists of:

1. Rope socket (Fig. 1).
2. Drill stem—a piece of soft steel about 4 inches in diameter and from 12 to 15 feet long (Fig. 2).
3. The bit, with a single cutting face about 5¼ inches long (Fig. 3).

When ground containing coarse boulders is being drilled there is a liability of the drill becoming wedged in the hole, and in order to prevent this a tool called the jars (Fig. 4) is inserted between the rope socket and the stem. It is like two links of a chain, and when the bit is caught these two links coming together with a shock jar the drill loose.

The whole string of tools, socket, jars, stem and bit weigh about 1200 pounds.

SPEED.—The driller makes about sixty 30-inch to 40-inch strokes per minute.

FUEL.—About a half cord of oak wood is burned per day of ten-hour shift.

WATER.—For drilling and washing the drillings about 1000 gallons of water is used per day.

THE OPERATION.—The land is surveyed and the location of the drill holes staked out and marked by flags. The drill is set up over flag No. 1. A hole is shoveled out to a depth of about 2 feet and the first length of casing is made ready. This section of casing or drive pipe is 5¼ inches inside diameter, ¼ inch thick, and about 5 feet long. It is fitted with a wrought steel drive shoe (Fig. 5) to protect the lower end from injury. This drive shoe is made 7¼ inches in diameter at the cutting edge and is slightly beveled inward. On the other end of this casing is screwed a steel driving head to prevent the threads from being battered during driving. This casing, so mounted, is set up in the hole directly under the suspended drill and tamped around with excavated dirt.

Drilling is now commenced. Water is poured in from time to time to thin out the material. After the ground below the foot of the shoe is loosened for a distance of say 1 foot, the casing is driven down and the loosened and thinned material removed by means of the sand pump (Fig. 6), a hollow pipe supplied with plunger and foot valve.

The driving is accomplished by striking the driving head with a couple of iron blocks clamped to the stem by means of two 1¾-inch bolts (Fig. 7), the weight of the string of tools acting as a hammer. After driving, the driving blocks are removed. When the first length of casing is driven down to head the driving cap is removed, a second section of casing is screwed on the first, the driving cap replaced, and drilling resumed. When the required depth is reached—determined either by striking "bedrock" or passing through the pay stratum—the hole may be considered finished, and the next step is to pull up the casing. This is accomplished by removing the bit, stem and jars, and replacing them by what is known as the pulling or pipe jars (Fig. 8). These consist of an iron boss fixed to the end of a rod 4½ feet long. Above the boss is a 1-inch-thick plate—the "knocking head"—provided with threads which are screwed into the sleeve of the top section of casing. The stem of the boss passes through a square hole in the plate. The walking beam is set in motion and the string of casings is raised by the boss striking against the knocking head. As each section of casing is raised it is unscrewed and the knocking plate screwed on the next. If care is used in keeping the threads of the casing clean, the casing can be used for a long time. It is rarely that a casing is lost. Fig. 9 shows the casing, drill bit, driving cap and driving head in section.

TREATMENT OF DRILLINGS.—The drillings extracted from the drillhole by means of the sand pump are discharged into a wooden trough 12 feet by 1 foot by 1 foot, set on a slight grade. From the trough they are run into the riddle of a rocker and rocked in the ordinary method adopted for washing gravel. Great

*Trans. Inst. Min. & Met.

care is taken to save all the extremely fine particles of gold, as upon this work depends the accuracy of the tests made. It is customary to clean up the results of each pumping, and to carefully note the number of countable colors obtained and the character of the ground drilled through. For instance, a page of the driller's notebook taken from actual practice is as follows:

HOLE NO. 14.

PUMPING.	COLORS.	REMARKS.
Feet.		
00 —10	1 speck	Red soil, clay, sand and fine gravel.
10 —11	22 fine colors	Gravel starts at 10 feet.
11 —12½	52 colors and fine gold	Fine gravel.
12½—13½	14 colors and fine gold	Coarse gravel.
13½—15½	4 fine colors	Gravel softer.
15½—16½	4 fine colors	Gravel softer.
16½—17½	8 fine colors (1 fat one)	Gravel coarse.
17½—18	7 colors and fine gold	Gravel coarse.
18 —19½	6 fine colors	Gravel coarse.
19½—20½	8 colors, some large	Gravel coarse.
20½—23	16 colors, some large	Gravel coarse.
23 —23½	16 fine colors	Finer gravel.
23½—24½	21 colors and fine gold	Finer gravel.
24½—25½	8 colors, fine gold.	Finer gravel.
25½—26½	13 colors, some large	Finer gravel.
26½—28	6 colors and fine gold	Finer gravel.
28 —28½	5 colors, fine gold	Finer gravel.
28½—29½	8 very fine colors	Stopped in fine gravel.

Water level 21 feet.

The term "fine gold" is applied to such specks as are too small to be counted, but which play an important part in making up the total value of the hole. The gold from each cleanup is put in a small dish.

This practice of cleaning up after each pumping (approximately after each foot of hole drilled), instead of one final cleanup, is all-important in furnishing data for a cross-section map, showing occurrence of rich streaks—sandy or clay patches, fine gravel, depth of overburden, of false bedrock and of water level.

After the last cleanup all the gold from the hole is collected by means of quicksilver, forming an amalgam. This amalgam is dissolved in nitric acid and thoroughly washed in hot water. A few drops of alcohol added to the wash water will prevent the spattering and loss of gold when the last drop of water is evaporated. The gold is annealed and carefully weighed. From this weighing the value of the ground at this particular spot is calculated, and the result given in cents per cubic yard.

Calculating the values is best shown by an example. The gold from say hole No. 14 weighed 2.22 grains; this at 3.95 cents per grain equals 8.76 cents—the value of gold from hole No. 14. The cubic contents of the hole is next calculated. To do this, a factor called the "pipe constant" or "pipe factor" is applied. The inside diameter of casing is 5⅞ inches; the outside diameter is 6½ inches. It is the practice of the district to use the outside diameter of the pipe as a basis for calculating its contents, the local engineers holding that it is the displacement of the pipe and not the cubical contents that should be used. Figuring the cubic contents per foot of pipe, with a diameter of 6½ inches, would give .23 cubic foot. In practice it is found that .23 is much too small, giving values too high, values not borne out by subsequent dredging.

Some engineers use .25 as a factor. "Radford's factor" is .27—a factor obtained by W. H. Radford, a mining engineer of wide experience in this class of work, by the following method: Mr. Radford sunk a hole 3 inches in diameter, using a drillhole as the center, to a depth of 34 feet. The gold obtained from the shaft corresponded almost exactly with the gold obtained from the drillhole when using .27 as a factor in the calculation. This factor is very important, as on it depends the value of the holes and consequently the final value of the ground. The difference in the results obtained by using either the factor .25 or .27 is sufficient to change the value per cubic yard from net to gross—i. e., a difference in some cases of 6 cents to 8 cents per cubic yard.

Continuing the calculation: Hole No. 14 was 29½ feet when drilling was stopped; 29½ × .27 gives 7.965 (cubic feet in the hole drilled). Now, we have the simple proportion, 7.965 (cubic feet of gravel drilled) : 27 (the number of cubic feet in a cubic yard) : : 8.79 (the value of gold obtained) is to X = the value per cubic yard, whence X = 29.69 cents per cubic yard.

(TO BE CONTINUED.)

Engines For Deep Winding.

During the course of a recent lecture in London, before the Institute of Civil Engineers, H. W. Maw, speaking of winding from great depths, said:

"No general solution to the problem of deep-level winding appears to have yet been arrived at. The author would refer those interested in this question to a paper by Mr. Hans Behr, read before the Institute of Mining and Metallurgy in May, 1902. The tendency is, however, to avoid stage winding, unless absolutely driven to it, on account of the double handling of the rock and multiplication of parts; and, by the use of tapering ropes and conical drums, to provide for such depths as are likely to be reached during the next few years. Neither the Koepe nor the Whiting system allows of the use of tapering ropes, nor do they permit of winding from single compartments in case of necessity. It may not be out of place to mention some winding engines now being built in this country under the supervision of the author, to wind from shafts 5000 feet deep on the incline, corresponding to a vertical depth of about 4000 feet. The load will consist of 12,000 pounds of rock, with a skip weighing 6000 pounds, the rope tapering from 4½ inches to 3⅝ inches circumference, and weighing 13,750 pounds. The engines are cross compound, each having one H. P. and one L. P. cylinder, 30 inches and 48 inches diameter, respectively, and 60 inches stroke, fitted with 'Corliss' gear. On the crank shaft are mounted two drums, each running loose and driven by friction clutches. These drums are partly parallel and partly conical, the latter portion tapering from 12 feet to 20 feet in diameter, and holding 1250 feet length of rope, the parallel part holding the remaining 3750 feet of rope, which coils once back upon itself. There are separate steam auxiliaries for operating the reversing and clutch gears and holding off the post brakes, which are put into action by heavy weights."

Head Frame, Shaft No. 4, Congress Mine, Congress, Arizona (See Page 17.)

Co-operative Mining.

TO THE EDITOR:—It is a singular fact that no instance of co-operative mining on a large scale exists anywhere to-day in California where the organization is composed entirely of white men.

It was a common thing during the past twenty years to find Chinese companies engaged in wing-damming and mining the rivers of this State, sometimes as many as fifty or more Chinamen being employed for months in building "cribs," filling them with rocks and boulders, connecting the cribs together, setting "bullwheels" and China pump, arranging dip wheel and flume for washing the gravel and, lastly, raising the derrick, fastened on either shore with its long guy-ropes; when all was ready to hoist out the gravel from the pit that was then sunk to bedrock.

During all these months of monotonous and uncertain preparatory work, all was under the direction of the "bossy-man," who, seated upon some high point commanding a clear view of the work, usually smoking from a hamboo pipe with a thimble-sized bowl (which never seemed to need refilling nor lighting), gave his orders in shrill-sounding "hi yas" and "muck-a-hi-los" to the slow moving but ever going colony of busy ants who, never questioning the wisdom nor shirking the unpleasantness of his orders, kept steadily rolling and lifting, picking and shoveling until all was complete.

The first clean-ups were devoted to paying expenses incurred for lumber, material and supplies; after these were paid, the money obtained from sale of gold was divided. If the claim proved a good producer, a barrel or two of "China brandy" (equivalent to our Jersey lightning), chickens by the dozen and hog, roasted a-la-barbecue, would be speedily forthcoming for, contrary to usual impression, John Chinaman is a good liver in his own way.

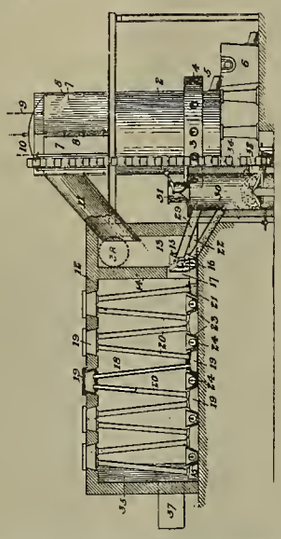
The Chinese system of mining in California has been on the co-operative plan, even in the many enterprises backed by the so-called "Chinese Six Companies," and many millions in profits have gone back to China although the placer beds and rivers were stripped of their richest values before the Chinese came on the scene, and they worked what was left by the white man.

It is said that "a wise man can learn from a fool." If so, he may also be taught something by a Chinese.

If co-operative mining is ever made a success by the white race, it will be when carried out along the lines followed by the Asiatics. If there is an instance on record where twenty, or as few as ten, white men in moderate circumstances have ever formed a mining company and hung together under adverse conditions, following the direction of a chosen leader for a year's time without disrupting, such combination has not come under the writer's notice. On the other hand hundreds of instances are known where valuable properties are lying idle, former fast friends now bitter enemies; properties now paying well that were abandoned or sacrificed, owing to non-agreement of co-owners.

The trouble is that none of us are as infallible as we think ourselves to be. The courage which permits one to say "I have made a mistake" is rare; the sensible and forgiving spirit which replies and

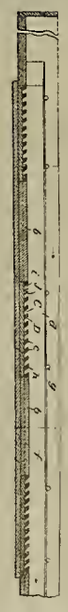
says, "All right, you'll know better next time," is still rarer. To know that it is better for one man to make one mistake than it is for twenty men to each make one mistake, a certain thing amongst twenty men, requires—well that requires horse-sense; something not taught in books. CHAS. L. LANG



Sonora, Cal., June 29.

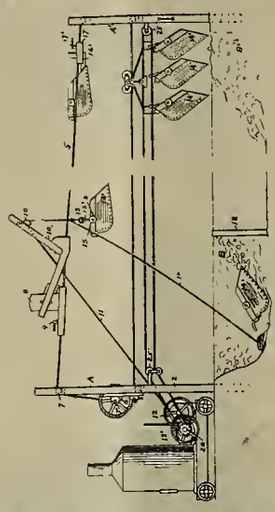
Mining and Metallurgical Patents.

PATENTS ISSUED JUNE 30, 1903.



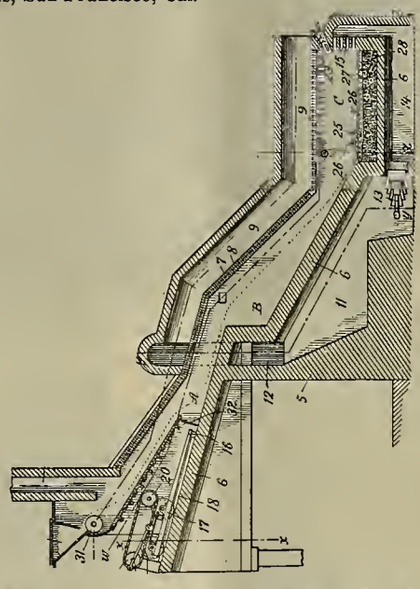
Specially Reported and Illustrated for the MINING AND SCIENTIFIC PRESS.

SMELTING PLANT.—No. 732,084; W. E. Koch, Pittsburg, Pa.



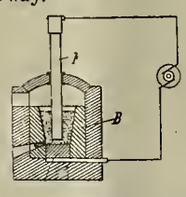
Combination with stack smelting furnace of dust-catching chamber connected with offtake of furnace, fritting furnace adjacent to and arranged to receive heated material from dust-catching chamber and mechanism for feeding fuel into fritting furnace in contact with heated material.

GOLD SEPARATOR.—No. 732,149; B. Westhaver, Mahone Bay, Canada.



Separator comprising dump box A, removable sluice box, plain surface sections arranged in sluice box, having rabbets f, removable riffle bar sections arranged in sluice box, alternately with plain surface sections, and and flush with plain surface section and bottom of dump box; riffle bar sections each having bed plate, and parallel, transverse riffle bars, upper and lower sides of which are straight, having riffles, between bars, bottoms of which are straight and parallel to surfaces of riffle bars, upper and lower sides of bars being inclined in a common direction from riffle bottoms, upper sides in a less degree than lower sides, whereby spaces of acute angle shape are formed between riffle bottoms and upper sides of riffle bars to retain gold, and riffles rendered wider at top than bottom to permit of free escape of pebbles, retaining strips bearing on bottom of dump box, in rabbets of plain surface sections and on riffle bar sections at ends of riffle bars, pins removably securing strips in sluice box.

EXCAVATING MECHANISM.—No. 732,172; W. Cole, Olympia, Wash.



Excavating apparatus comprising removable supporting frames located a predetermined distance apart, inclined trackway suspended therebetween, excavating scoops, means for drawing scoops against the earth to load same and elevating filled excavating scoops and placing same onto suspension trackway, means adjustably connected to trackway for regulating the length of cut for scoops, devices located at lower end of trackway for causing scoops to automatically discharge excavated material carried thereby when end of trackway is reached.

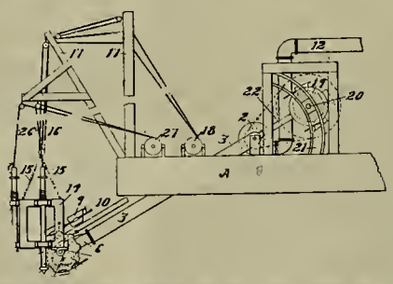
METALLURGICAL FURNACE.—No. 732,264; M. P. Boss, San Francisco, Cal.

Metallurgical furnace, comprising inclined calcining chamber, inclined reducing chamber, horizontal oxidizing chamber, chambers connected at progressively lower levels; means for producing required atmospheres in chambers, and means for heating air fed to oxidizing chamber, means consisting of chambers located over and under oxidizing and reducing chambers.

MANUFACTURE OF SILICON AND ALUMINUM FROM SILICATES OF ALUMINA.—No. 732,410; C. H. Homan, Christiania, Norway.

Method treating materials containing silicates alumina, such as clay, for obtaining silicon and slag containing aluminum oxide consisting in mixing material with metallic aluminum in pulverized form, exposing mixture to high-temperature electric or other furnace, thereby reducing silicic acid and other reducible bases and finally tapping off resulting products.

PROCESS OF LEACHING ORES OR TAILINGS WITH SOLUTIONS OF ALKALINE CYANIDES.—No. 731,590; C. W. Merrill, Alameda, Cal.



Improvement treating ores or tailings containing reducing agents with solutions alkali metal cyanides which consists in oxidizing reducing agents with alkali metal or alkaline earth metal hypoclorite, subsequently treating ores or tailings with solution of alkali metal or alkaline earth metal cyanide.

ORE CONCENTRATOR.—No. 732,319; E. B Rogers and F. P. Hanson, San Francisco, Cal.

Laterally inclined, vibrating ore concentrating table having surface divided by riffles extending longitudinally thereof, and in general direction of vibratory movement, riffles at high end of table being arranged uniformly close together for short distance, remaining riffles upon table being arranged uniformly comparatively far apart, and intermediate riffles arranged to extend from line extending diagonally across the surface of the table, over portion thereof containing widely arranged riffles.

DREDGER.—No. 732,538; W. H. Fulcher, Oakland, Cal.

Combination in dredger of suction apparatus and chain buckets traveling proximate to inlet of apparatus, buckets having open-work girds to allow finer material enter suction pipe and arrest coarse material.

EXTRACTING GOLD OR SILVER FROM SLIMES.—No. 731,631; J. T. Terry, Jr., Altar, Mexico.

Improvement separating precious metals from slimes, consisting forming solution with water, spraying solution into tanks containing cyanide solution made dense by addition salt, allowing slime to settle through and into solution, then drawing clear liquor from top through vertically disposed filters and discharging sludge from bottom into succeeding tanks containing similar cyanide solution, allowing it settle and again drawing off clear liquor.

SULPHURIC ACID PROCESS OF EXTRACTING PRECIOUS METALS FROM SOLUTIONS.—No. 731,839; G. A. Bahn, Austin, Tex.

Process precipitating precious metals from solutions thereof, consists producing cyanide solutions of precious metals, acidulating with sulphuric acid, immersing zinc in sheet, plate, or other form in acidulated cyanide solution containing precious metals; chemical action thereupon taking place in solution, dissolving zinc and precipitating precious metal; recovering from precipitate of preceding operation, precious metals, by filtering and melting, or other process.

GOLD-EXTRACTING PROCESS.—No. 732,639; T. B. Joseph, Mercur, Utah.

Process extracting gold and silver from ore when in suitable condition, by subjecting ore to leaching action of solution containing water, cyanide of potassium, bromine, hydrate of calcium, peroxide of barium and carbon dioxide, and simultaneously agitating ore, by compressed air forced upward through same.

Cascade Water, Power & Light Co., Cascade, B. C.

Written by W. G. McConnon.

The recently completed plant of the Cascade Water, Power & Light Co. is situated at Cascade, B. C., and owned hy the London & British Columhia Goldfields Co., Ltd., representing an investment of $500,000.

Cascade is a small town on Kettle river, 12 miles east of the town of Grand Forks, and ahout 30 miles directly west from Rossland, B. C. Flowing from the west, the Kettle river descends 120 feet in passing through a half mile of narrow, rocky gorge in a series of rapids and falls. For the utilization of this natural power, the Cascade Water, Power & Light Co. has huilt a large dam, waterway, pipe line, power house and transmission line from Cascade to Phœnix, where the largest copper mines in the Boundary district are situated.

The dam, placed ahove the entrance to the gorge, is of timher crih work, with a 40-foot hase and 24-foot top. The midsection is 50 feet high, tapering to 25 feet at the sides, while the total length is 400 feet. It is huilt on solid rock hed to which the foundation timhers are holted, and filled with 10,000 cuhic yards of rock. This dam raises the water 36 feet ahove the natural level, giving an effective head at low water of 156 feet.

The permanent water level is 10 feet helow the top of the dam, heing controlled during high water hy twelve sluice ways, which can he opened to 12 feet helow the natural river level, giving a passway of ahout 2000 square feet. These sluices are closed hy means of 12x12-inch squared timhers in grooves, operated hy a traveling winch running on a track over the top of the dam.

From dam to power house the water first passes through a 225-foot open rock cut from which it enters a tunnel driven through 410 feet of solid rock and into another open rock cut 500 feet in length, at the ends of which the hulkheads and controlling gates are located. These cuts and tunnel represent an excavation of ahout 35,000 cuhic yards of rock.

From the gates the water is conveyed through a wooden pipe, 7 feet in diameter, for ahout 1400 feet. This pipe is constructed of Oregon fir tongued and grooved staves, 2¼x7 inches, cut in circular segments and machined to the radius of the pipe. The staves are hooped at 12-inch intervals, with ¾-inch round steel hands, with cast-iron connecting shoes for clamping.

Sub-Station, Line of Cascade Power Co , Phœnix, B. C.

Provisions have heen made at the hulkhead and in the width of the cut for the installation of a similar and additional pipe.

From the stave pipe the water is carried through 250 feet of circular steel pipe, 7 feet in diameter, resting on concrete piers and anchored into solid rock to avoid end thrust. At the power house, three 4-foot pipes and one 2-foot pipe are taken off helow the floor level to supply three 36-inch turhines for generators and two 12-inch turbines for exciters.

The engraving gives a general view of the power house showing the stand pipe at the junction of the stave and steel pipes.

In the interior of the power house the three generators are standard Westinghouse, three phase, two-hearing, direct-coupled, 2200-volt, 750 K.W. at 80% power factor, or 940 K.W. at 100% power factor, 60 cycles per second, 300 R.P.M. The two exciters, each capahle of exciting all three generators at one time, are 45 K.W., 120-volt, shunt-wound dynamos, self-contained, two-hearing type, direct coupled to independent turhines, with 500 R.P.M.

There are in all nine transformers, which are Westinghouse, self-cooling, oil-insulated type, having a capacity of 250 K.W. at 80% power factor, or 312½ K.W. at 100% power factor, "Star" connection, and wound for a ratio of 2000 to 20,000 volts, on hoth high and low tension windings, with full load efficiency of 97.6%.

There are six lightning arresters, located just ahove the switches in the gahle of the roof, of the low equivalent style, giving protection against lightning discharges for transmission at 20,000 volts.

A right of way 132 feet wide is cleared, and transmission lines erected from Cascade via Grand Forks to Phœnix, a distance slightly over 21 miles.

The high-tension circuit consists of two separate three-phase transmission lines, each carrying three No. 3 B. & S. copper wires, with room on each line for another circuit.

The poles are heavy cedar, and on tangents are spaced not over 100 feet apart, on curves at less distances, in some cases as low as 50 feet. No angles are turned, but all changes in direction of line made with easy curves. No side or head guys have heen used except at extra heavy spans across rivers, etc.

The work on this line, as well as all construction of the plant, was designed and executed hy William Anderson, the company's engineer.

A 3-mile feeder is taken off at Grand Forks, 12 miles from Cascade, to the Granhy smelter, where current is used for driving Westinghouse induction motors of sizes ranging from 3 to 700 H. P., and of an aggregate capacity of 2400 H. P.

One of the accompanying engravings is a view of the suhstation at Phœnix, located at an altitude of ahout 3500 feet ahove the power house. The huilding is of hrick, with one end left for future extension, and contains the transformers, line switches, fused circuit hreakers, switchhoards, etc., suhstantially duplicating those at the power house. This suhstation, for the present, will supply current for two 700 H. P., Westinghouse, type "C" motors for driving two large compressors, a 100 H. P. motor for stone crusher, and a 150 H. P. motor for hoist, as well as furnishing the current for lighting the town of Phœnix.

The Cascade Water, Power & Light Co. estimates that it will have a supply at low water for ahout 6200 H. P. This will enahle the douhling of the present output.

Power House and Transmission Line, Cascade Power Co., Cascade, B. C.

A Proposed Signal Code.

The following is reported to he the signal code officially adopted hy the Western Federation of Miners at their recent national meeting in Denver, Colo., which they desired to he used in all the mines west of the Missouri river and in British Columhia:

1 hell, hoist or stop if in motion.
2 hells, lower cage.
3 hells, hoist men to surface.
2–1 hells, lower to next level.
1–2 hells, hoist to next level.
4 hells, hlasting signal. Engineer raise cage few feet to show attention, then 1 hell, hoist men from hlast.
5 hells, turn on steam.
6 hells, shut off steam.
7 hells, turn on air.
8 hells, shut off air.
9 hells, danger signal.

A code of special signals was also adopted for special work.

[One would suppose that a committee presumahly comprised of practical miners would devise a more satisfactory code of hell signals than that ahove given, which is defective in many respects. One hell to hoist, or to stop if in motion, is all right, and two hells to lower empty cage, skip or hucket is as good as could he devised, hut the proposed code makes no provision hy which the engineer may distinguish hetween a vehicle carrying men and one going down empty. The signal 3–2 is hetter, and to hoist men the signal 3–1 fulfills every requirement, as it signifies to the engineer that human lives are dependent upon him and he will naturally exercise more caution than he would with a load of rock. The third signal in the ahove code, 3 hells, hoist men to the surface, is also defective, as it only indicates that men are to he hoisted and gives no premonitory signal. When men are to he hoisted the signal 3–1, as ahove indicated, is a good one, as the engineer not only knows he has men to hoist, hut knows hy the final single hell when they are ready. The chief fault, however, lies in the fact that it is unlike any of the codes already in use in many regions and in no particular is hetter than any other code. The necessity for a universal hell signal code has long since heen recognized, and this action on the part of the Western Federation is in the right direction, hut it could he amended greatly to its advantage, or at any rate to the advantage of the thousands of miners who are ohliged to depend upon hell signals in mines for safety.—Ed.]

Filter-Press Treatment of Gold Ores and Slimes By Cyanide.

NUMBER II.—CONCLUDED.

In the construction of the filter press there have been taken into consideration every factor that has led to the successful treatment of the finely pulverized ores by filter-press cyanidation in the Kalgoorlie gold fields of Western Australia.

There are so many different types of filter presses used for various purposes throughout the world in the manufacture of different products, that the first originators of the process had a large range to select from; but it was found that the proper form of press adapted for this work is that known as the "flush plate and distance frame" form of construction.

That is to say, a series of plates or filter frames, covered with filter cloth, having distance or cake frames to hold them apart and to form the depth of the chamber; these are screwed up between the head and the follower of the press so tightly that all the joints around the rim of the plates and frames are water and air tight under the working pressure of the machine.

This gives a battery of filtering cells, lined on the interior with filter cloths, and having under the filter cloth on the surface of the plates a drainage for the liquid which filters through at the back of the cloth.

The mode of the construction of the filter frames to allow ready drainage of the fluids is important, as the efficiency of the machine to a considerable extent depends thereon.

There are three principal forms used. One is the plain channel surface that has the center of the plate, beyond the joint surface, channeled with grooves from top to bottom, all over the surface of the plates, and a cross groove or two collects the filtrate from the vertical channels to deliver it to the outlet. Another is the pyramidal filtering surface, formed by having the whole of the surface dotted over with small flat-topped pyramids, over which a cloth is placed.

But these are defective systems, because the filtrate, in passing through the cloth, has to pass along the grooves formed by the channels between the pyramids, down to the point of exit, and any fine particles of pulp which may be forced under pressure through the cloth collect and form obstacles for the free passage of the fluids.

Another objection is that the cloth stretches and sinks between the channels, making an irregular surface for the pulp, and also considerably diminishing the area for the free discharge of the fluids.

There is another system that has been used heretofore, of utilizing perforated sheets laid over a corrugated or grooved surface, the chief objection to which is the small area that these grooves give to the discharge of the fluid, and should any clogging occur at the back of the perforated plate it effectually prevents a uniform filtration.

In this filter press and process herein described—that of the American Filter Press Co. of Denver, Colo.—improvements have been made based upon long experience of the company in filter press cyanidation. The filter frames are formed with solid rails, having transverse and longitudinal ribs placed about 2 inches apart. These ribs are again cored internally with a series of slots.

The perforated steel plate is placed over these ribs,

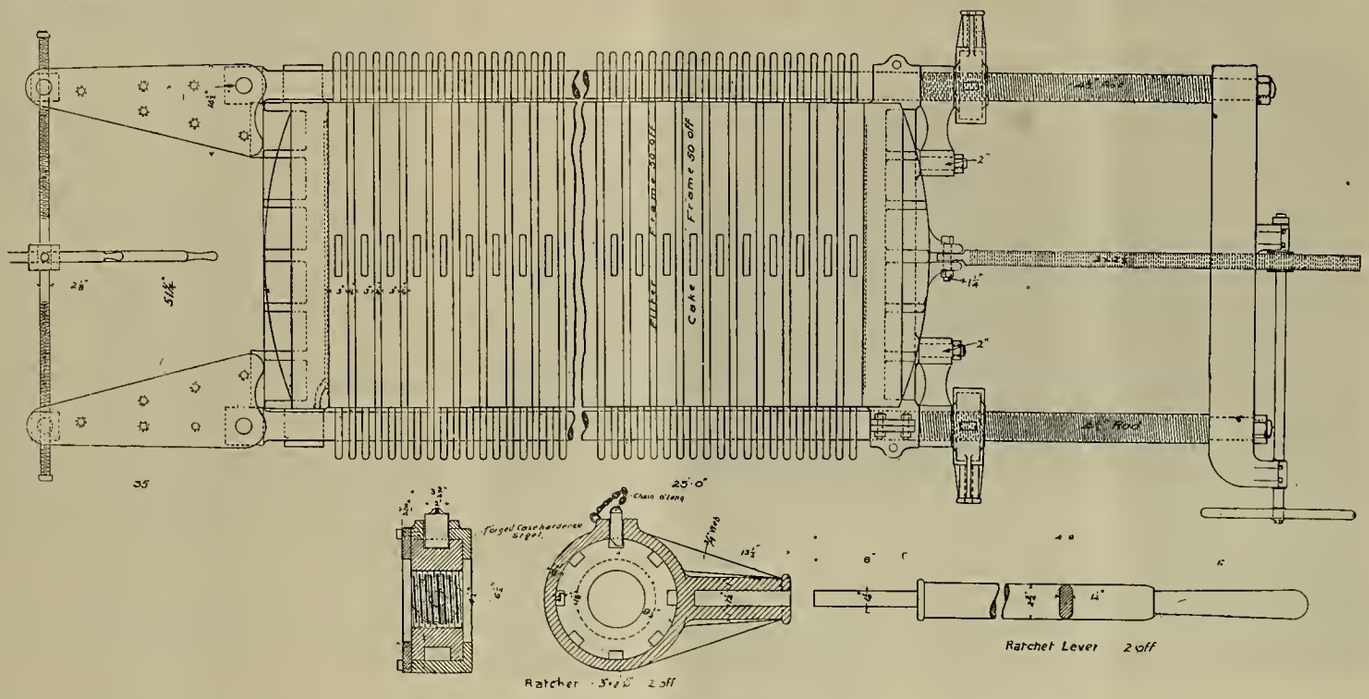


FIG. 1.

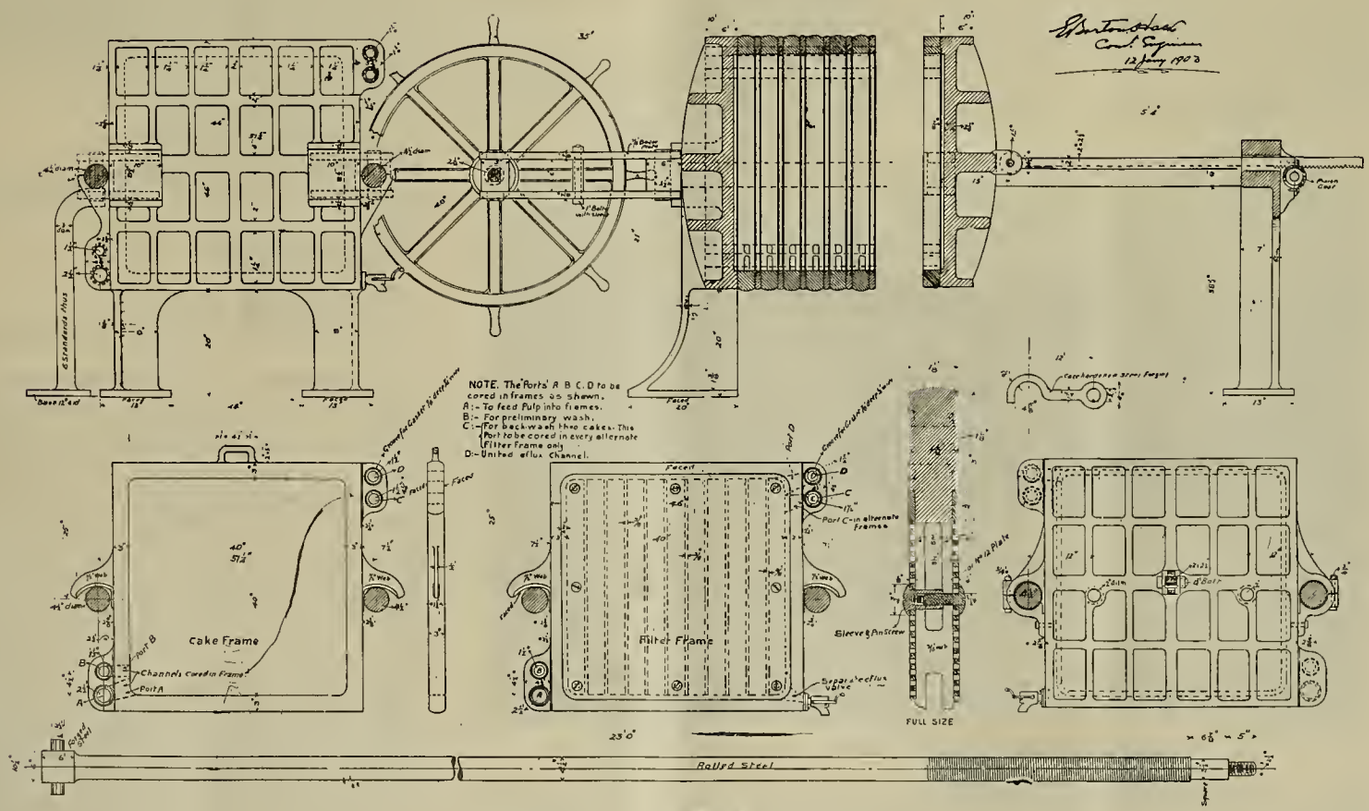

FIG. 2.

one on each side, and fixed with flush-headed sleeve and pin screws. The formation of the internal ribs allows the fluid passing through the plates a large area of exit, with no possibility of any accumulation forming at the back of the perforated plates, while the flush surface of the filter frame, over which a cloth is placed, gives a minimum friction and wear to the cloth.

The objection that the perforated plate gives a smaller area to filtration than the pyramidal form of surface, is of little effect. Long experience and tests of both methods have proved that the perforated sheet filtration is of far greater service in the life of the cloth and economical working of press than any other form and gives as efficient extraction.

The next point of importance is the construction and arrangement of the different passages for charging the chambers of the filter press, for drawing off the filtration therefrom and for introducing the wash fluid at the back of the cloth in one series of the chambers, so as to press through the cake, thus forcing out the gold-bearing cyanide solution from the cakes.

The system of construction for all these passages is a continuous channel formed by the juxtaposition of a series of holes formed in the plates and frames, which when placed together form a pipe passing from end to end of the machine.

This pipe has cored passages or ports, either through the distance frames, or in connection with the internal portion of the filter frame, according to the purpose for which they are intended to be used. There are four channels to each plate, each of which has a specific purpose.

These channels are formed two to each side of the frames, the lower channel at the bottom being for charging the chambers; the second, immediately above, for the washing fluids and for compressed air; the third, being the lower of the two upper channels, for passing the washing fluids into the back of the frames; the fourth, or upper channel, being a common efflux for the fluids.

There is also attached to each filter frame a separate discharge valve of special construction, an easily opened and simple mechanical device which will add to the facility of working the press. By this means the filtrate can be run off in full view of the operator.

The joints between the plates and frames immediately around the channels are made by means of round rubber rings let into cored channels just the right depth to allow the rubber to project sufficiently to make a tight joint.

The whole of the channels are projected beyond the main face of the frames, so as to allow the filter cloth being passed over the filtering surfaces without the necessity of cutting or trimming.

The next point of importance is the construction of the framework of the machine.

The tension rods on each side are round, supported intermediately with cast iron standards. These efficiently counteract the sagging that would be caused by the great weight of the chambers of the machine. The tension bars are threaded at one end, on which a friction saddle piece travels, connected with the end plate of the chambers; and beyond this again is a pawl-and-ratchet arrangement for the preliminary tightening up of the frames. At either end of the tension rods there is a lever arrangement attached to each rod.

The fulcrum of this lever engages with the end plate of the machine, while the two ends of the levers are joined with a right and left hand screwed rod, to which is attached a large handwheel. By screwing up this rod, the two ends of the lever travel towards each other, drawing the side tension rods towards the end of the press, at the same time forcing the end plate inversely towards the opposite end of the machine. An enormous purchase can be obtained by this means, insuring absolutely close joints to all the frames.

The whole of the tightening up of the press occupies but a few minutes, and the workman is in the best position possible to exercise his strength most effectually for the work intended, one man being able to attend to at least three machines.

It is unnecessary to do more than merely refer to the use of filter presses for the purpose of extracting the superfluous fluids, or washing the sulphate of zinc from gold-zinc slimes. Presses have been used for this purpose in so many mills throughout Colorado,

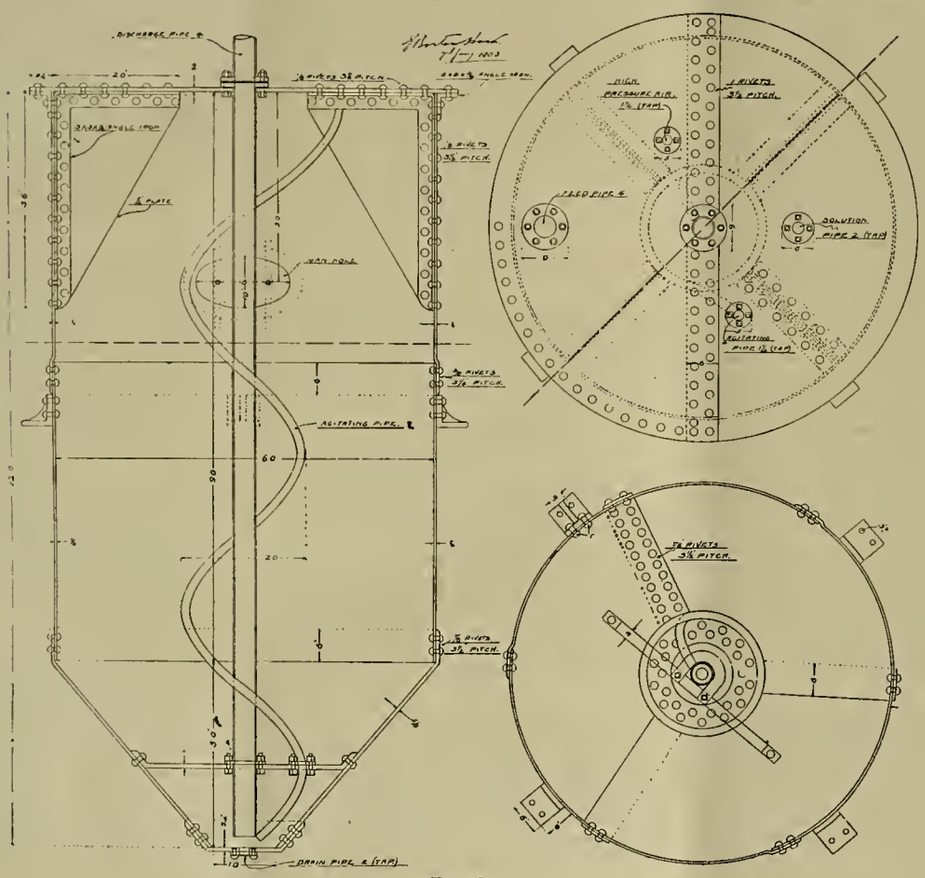

FIG. 3.

Wyoming and Utah that most metallurgists understand and realize the value of them in the "clean-up."

The accompanying drawings show the construction of a full size 40x3-inch fifty-chamber filter press of about five-ton per charge capacity, the position and uses of the feed and wash channels and the devices for closing and opening the frame, also the pressure tank, or Monteju, fitted with agitating voluted perforated pipe and other fittings.

Direct Steam Ore Stamps.

Written for the MINING AND SCIENTIFIC PRESS by CHARLES H. FITCH.

A little boy going through a cemetery with his mother read the praises of the deceased engraved upon marble and granite and asked her if only the good people died. Steam stamps as machinery on a commercial basis for milling gold ores are dead. When they were a live issue and an effort was being made to make a market for them by good advertisers no sweeping words of criticism were in order. We perceive this distinction, that fair words are spoken of deceased people but of live machinery.

So long as manufacturers were trying to make the direct steam stamp a success in competition with gravity stamps conservative men were willing to await the issue, thinking that something might be worked out which would be a practical success, and enable mines to be developed with greater economy.

One of the brainiest independent engineers this country has produced is John Richards of San Francisco, and when he discontinued the publication of his monthly magazine, "Industry," it was a calamity, a calamity which might have been averted if he had enlisted a good advertising man in the management of that interesting publication. A long time ago I clipped from "Industry" a brief editorial by Mr. Richards calling attention to the indirection of milling ore as it is usually done under gravity stamps, and commending the idea of direct steam stamps.

The great steam stamps used on ores of copper in the Lake Superior region may be considered successful, as they are in large use and nothing succeeds like success. They are, however, open to criticism on several grounds, and the precedent of using them was inaugurated by companies of great wealth having "money to burn." In this article I do not consider these stamps. A few of them were used on gold and silver ores, but sliming and the difficulty of connecting them properly with amalgamating appliances and concentrating machinery soon "killed them."

I kept John Richards' editorial stuck up before me, thinking that I would some time design a steam stamp, very much in the spirit of that modest Texan editor who proposed to eclipse old Shakespeare "when he had time." I may yet design the stamp and there is a Kentuckian named John Fox, Jr., who may yet give Shakespeare a run, and again we may not.

There are two features which I think would go far toward making a success of a small steam stamp. In the first place it must have an economical engine. The most economical small direct-acting engine ever built was one designed by Elihu Thompson. It had four 2½-inch by 3-inch cylinders, realized 5 H. P. and used only twenty and one-half pounds of water per horse power per hour, a good enough performance for a large compound Corliss engine. It had four single-acting trunk pistons, puppet valves, and carried 160 to 200 pounds pressure, steam always flowing one way without reversal of flow. It was a simple engine, and might have given better results with one larger cylinder. I would get some points of design from this engine.

And I would use cam path and wiper to work the steam valves. This valve motion has done more than any other feature to make the steam hammer the wonderful success that it has been. The "Wood" stamp put upon the market some years since by Henry A. Newkirk & Co. had a valve gear approximating this idea. This stamp "died a-horning," although several of them were put to use, including a battery of several by the Dwight Furness Co., Guanajuato, of which a favorable report was made after a short run.

The beauty of the cam path and wiper device is that it does in a simple way a thing which is otherwise very troublesome and difficult to do—that is, times the valve action to the fall of the stamp or hammer so as to open the steam valve after the falling weight is down. The descending weight outruns the wiper, and the latter from lagging has a small movement of "catching up," which is a deferred motion derived from a motion which has ceased. The hammer ram impelled by weight and steam pressure falls more rapidly than the wiper impelled by weight alone. If, however, a steam stamp was allowed to operate by gravity, only being lifted by steam, the fall of the wiper might be retarded by a small spring.

The Tremain mill, the most widely used of small steam stamps, had some success. The struggle to make it a success by a strong company having excellent engineering talent was a determined one. Adjustment of valve gearing to work of stamps as the shoes and dies wore required careful attention, and the whole mechanism was too complicated and liable to balk. Yet with judicious care it would work perfectly on long runs. The design suggested a duplex vertical steam pump, and steam pumps are notoriously great eaters of steam. A large battery of these steam stamps put in at the Regina mine in Ontario gave them the greatest trial they have ever had. The result was a low economy, so that the selection of these stamps was branded as had management. This blind-sight evidently served as foresight to discourage further investors.

The American steam stamp had one excellent feature, the wedge base by which the height of die could be readily adjusted without disturbing the valve relations. This stamp was the successor of the Wood stamp, but to make a difference of design the wiper was abandoned and valves were operated by rocking toggles. The first stamps had 12-inch stroke and delivered up to 200 heavy blows per minute. But the valve motion was defective in its proportions and breakages of valve and stem occurred. Then stamps were built with a shorter stroke—only 8 inches. The result was disastrous, as the valve motion would only then give a maximum of 150 strokes, and the blows were light and comparatively ineffectual. A few inches of ore banking upon the die would bring the stamp to a stop. The defects were those of design and proportion. With plenty of steam hammers in the same shops operating with cams and wipers so as to maintain any desired stroke, it was alleged to be impracticable to run a

steam stamp this way, and a small Brotherhood three-cylinder engine was rigged up to run the valve gear. This was both unnecessary and unsuccessful, as the engine was not properly governed, and the speed not heing controlled nor co-ordinated with the time of drop, the action of the mechanism was erratic and discontinuous.

None of the steam stamps described are heing actively manufactured and pushed on the market, and yet it is not improhahle that other attempts will he made to introduce these machines. It seems, therefore, a good time to call attention to some inherent disadvantages of these stamps.

The first is lack of steam economy. The only way to overcome this is to use superheated high-pressure steam in a special engine. The steam ahout mines is usually wet, and low pressure, and economy in the generation and piping of steam is a general improvement to he made in small mining outfits. But such outfits must he cheap in first cost and this makes them dear in running cost. As a rule, small steam engines are extravagant in the use of steam.

The second is complication of function. It may look more simple to stamp direct than to have an engine, helting, tightener and cam shaft, hut the latter arrangement admits of analysis and separate treatment. The direct stamp puts too much into a compact space, too many vulnerable and conflicting points of attention. The taking up of wear of shoes and dies, replacement of cams and stems, piston rings, stuffing hox packing, guarding against steam leaks under vihration, and the insidious escape of oily particles from steam or luhricant, provision for amalgamation and cleanup, valve adjustment and adjustment of feeding ore—these are hunched together, and if anything gets out of order the chain of trouhle hegins. There is usually plenty of room for a simple engine, helt and cam shaft with stamps, and each can he put right without involving any other feature, which is in much hetter shape for the millman to handle. The rule is, divide, classify and conquer. But with the steam stamp we comhine, complicate and perhaps swear horribly when some little essential piece is hroken and we are "40 miles from any place" where good repair facilities are to he had.

Another thing is to he noted, not as a disadvantage, hut as an overrating of advantage, the advantage of cheapness. A direct steam stamp to he thoroughly satisfactory has got to he a higher class of machinery than a plain throttling engine and a cam shaft. If made chiefly of steel and carefully fitted it will cost nearly if not quite as much as a gravity hattery and engine of the same capacity. And the remaining equipment, hoiler, stock, plates, concentrating tahle, huildings, tramway connections, quicksilver and supplies cost just as much with a steam as with a gravity stamp, and a saving of 25% in the cost of stamps is reduced to a saving of perhaps 8% or 10% on mill equipment complete. If the gravity stamps involve less risk, this small per cent is a good insurance. Nor is there much saving in foundations. Among some millmen it condemns a thing to call it self-contained, they have heen so often misled hy representations in this respect. If the mill is properly placed, and the approaches properly graded, the necessary excavation, cement work, retaining walls and timhering cut a figure which makes any difference in cost of foundations of the two kinds of mill comparatively insignificant. In short, the steam stamp for small prospecting mills has heen unsatisfactory. If improved in weight and design to he more satisfactory, the gain in cheapness disappears.

The idea of direct stamping is an idea of simplification of mechanical power, but the prohlem is like an algehraic expression containing several quantities to be solved of which this is only one. The attempt at solution hy means of steam stamps reduces one quantity to simpler terms of solution, hut the others, amalgamation, luhrication, adjustment, continuous repairs and automatic feed, are left in no hetter shape for solution, but in a more troublesome form.

Pencellier and Lupkin separately discovered their celebrated exact parallel motion immediately after a German engineer had written a "scientific paper" proving to his satisfaction that an exact parallel motion could not he made from the elements they used. So, while we are pronouncing against the steam stamp, some one may he working out some clever device which will "do the trick," justify Mr. Richards' editorial opinion, and confuse our negative argument, showing us that there are "more things than dreamed of" in our philosophy. I do not expect it, hut for mining interests would be pleased to have it so.

Iron Sands on Lake Superior.

On the north shore of Lake Superior, on the Canadian side of the lake, east of the Nipigon river, are large areas of hlack magnetic sands, rich in iron, and it is reported to he the intention of Philadelphia men to develop these beds of iron sand, and if found feasible, to dredge and concentrate the sand and ship the concentrates to iron furnaces, says the American Manufacturer. The ore can, it is stated, be made very pure hy washing from it the silica. The Eastern men interested have secured concessions from the Canadian Government on shore and other necessary rights.

Mining With Machine Drills.

Written for the MINING AND SCIENTIFIC PRESS by E. L. LE FEVRE.

It is not intended in this article to technically discuss the construction or theoretical efficiency of the various types of machine drills actively exploited hy manufacturers. The rapid advancement of the mining industry, particularly the metalliferous branch, has hrought out in a forceful way the necessity of ahandoning the old "single jack" with two holes resultant from a shift's work, and suhstituting therefor a power equipment capahle of largely increasing the tonnage output with a minimum expenditure for lahor.

A decade ago an ore hody must needs run up in the "pictures" to gain the title of honanza for a mine. Now the great fissures, contacts and chimneys of ore, low in grade, hut vast in extent, are eagerly sought after hy shrewd mining investors.

The ownership of a giant fissure vein does not necessarily imply wealth to the corporation or individual possessing title, even if the values be in the rock.

A close proposition may make or break a company through its management. A superintendent may possess technical qualifications in extenso; he may he soher, honest and energetic and yet fail to produce results and dividends. He lacks that rare faculty of grasping the essentials of economic mining. Men possessing this trait can command their own price. In the light of modern progress no manager can ignore the advent of an economical agent replacing the "single jack" and its two holes a shift.

When careful investigation shows that a great tonnage can he outputted with unfailing regularity, and equally rigid testing proves the possihility of milling this product successfully, then, and not before, is the property ready for the installation of power drills.

The source of power is a matter for the competent mining engineer; its application specifically to rock hreaking is the superintendent's husiness.

Having the requisite conditions and an intelligent directorate, a careful manager huilds for time, knowing well that a hig repair and depreciation dehit is not relished hy the stockholders' auditing committee. The power plant should he modern in every respect, with an emergency factor of at least 25%.

The use of air power heing justly prominent, I propose treating the suhject from this view point.

The machine drill is nothing more than a strongly constructed engine, calculated to furnish a maximum efficiency from a minimum of power.

For practical work in stoping out a vein, it may weigh from 95 to 400 pounds. For driving tunnels or levels the small, or "chippie," machines are rarely used. Primarily the efficiency of all standard piston machines depends upon ample power and efficient handling.

Various distinctive features, such as throttles, valve action, springs or rubber huffers to secure resiliency in the hack head and ingenious devices for regulating the air cushion inside the cylinder are ably presented to mine owners hy the manufacturers of standard machines. For the purposes of this article it is unnecessary to go into details of various types or draw comparisons between good and poor machines, as hardly a drill on the market is without some redeeming feature.

In deciding on a drill equipment a mine manager unfamiliar with the suhject in minute detail should never hesitate to call in the professional services of some one capable of giving skilled technical and practical advice absolutely unhiased. Any drill offered for sale must he safe to handle; the operating mechanism heing held together by side rods, the breaking of which stops the machine instantly with no further harm than a slight delay to replace the broken stay, makes runners confident to a degree.

For a guide in selecting a type of machine no general rule can he laid down. Broadly speaking, a 3 to 5 foot vein of medium hard rock, uniform in structure, can generally he worked to the best advantage with small machines. They require only one man to run them, are easy to set up and take down and require only a moderate power to run a dozen. They are designed to do about the same class of work as single jack miners, the economy in their use resulting from an increased tonnage hroken. Approximately, a "chippie" machine will do the work of three good miners. Still there is room for improvement in this class of drills, as at present the power required to operate one is too great. The hest field for the electric drill is in naturally ventilated mines, suhstituting small air drills on the class of work to which the latter are adapted.

The "chippie" drill, using ¾-inch to 1-inch steel, must have a homogeneous rock and requires an arm to the bar, as slight variations in the texture of rock, within limitations, may he drilled successfully if the machine has universal motion, and erratic action is at once corrected; on the other hand, a slippery formation with intrusions of varying hardness requires the highest skill in the machine runner, and is frequently worked at a loss with machines weighing up to 150 pounds, compared with hand work.

The large machines, weighing from 275 to 450 pounds, are good for any size of vein over 4 feet wide. The harder the rock the greater the economy from their use.

Some machine makers lay great stress on rapidity of action with short stroke, and quote figures in suhstantiation of their claims. In all instances coming under my notice exceptional conditions ohtained to produce such superior results. It is a patent fact that a given piston area suhject to impulse from air, moving ahead 6 inches at a stroke, will cause the drill to do more execution in rock than one moving 4 inches, even when the speed of the short stroke machine is accelerated 50% over the long stroke engine, all other conditions heing equal.

The question is frequently asked a maker, "How much will your machine do?" Results of trials under exceptionally favorable conditions are usually handed out with a flourish. While these statements are strictly true, yet they are misleading in that the same drill won't do within 50% of that work in general, practical use inside a mine.

While there is no hard and fast rule for estimating the rock-hreaking capacity of a drill, still a reasonable approximation is possihle; for instance, a first-class machine weighing 300 pounds, working under 100 pounds air pressure 16 hours a day, should hreak 1000 tons of quartz ore a month on a vein averaging 7 feet and should easily keep the stope filled in with waste in addition. No machine should he selected for stope work that will freeze up when cold, moist air is used, nor should one he used that has a multiplicity of delicate parts liable to hreak from the rough usage to he expected in a stope. Broadly stated, the choice should he confined to those that can he completely adjusted mechanically, with ordinary wrenches inside the mine. No matter how good the machine, its use is an expensive investment unless it is efficiently handled.

A man to whom a machine drill is intrusted should he a strong, active rustler. He should know enough ahout applied mechanics to readily grasp the working principles of his engine, and he ahle to diagnose the dozens of ailments to which it is liahle, and cure them at the least cost of time. He should he fertile in expedients, cleanly in hahit, clear headed in emergency, careful of his tools, and ahsolutely devoid of passion under stress of work. No angry man can reason clearly, nor should a valuahle machine he given into the care of a person suhject to violent displays of temper.

It is the runner's duty to direct the setting up of the machine, point the holes, correct adjustments, supervise every detail of drilling, see that the machine is in proper order, repair breakage and load and spit the holes. He should take a persoual interest in educating his helper up to a high standard of excellence, for the cogent reason that he lessens his own lahor therehy if for no other.

The helper should he a strong, willing worker, with a thirst for useful information. (If there is a place on earth where a shirker is out of place, it is around a machine drill.) Every detail of his work calls for strength, activity and unceasing application. The helper should learn to do things without heing repeatedly told. Wedges, hlocking, tools for leveling up, oil for machine and drills are things he should provide and put away when "tearing down." He should carefully note the hole angles and cultivate the hahit of observing in minute detail. A respectful demeanor, a willingness to do a little more than is required and a close mouth will soon gain the good will of the runner, hesides making the task much easier for both. After a short service he should take his turn with the runner in picking down and making the "ground" safe. This is one of the most important details of mining and should he given more attention, for personal reasons, than any other. It is a curious fact that few miners, comparatively speaking, know even the rudiments of securing safety without an excessive waste of time and energy.

The suhject of "dressing" a stope intelligently is much neglected and deserves more attention from miners. Every machine should have a full complement of first-class tools. The hig machines should have two chuck wrenches, 24 to 28 inches long, made of high-grade mild steel, and hent at an angle of 20° 5 inches from the tip of the jaws; a 16-inch Coe wrench for bolt nuts and hose couplings complete the hose equipment. The hars should he straight welded and riveted wrought iron pipe with the shoes and jack screws securely holted into place; a hent har will not remain rigid no matter how tightly it is jacked.

A scraper of proper length for cleaning out holes and a small rod of ⅝-inch iron, sharpened at one end, and 4 inches long should he with every outfit. Where wedges must he made, a short-handled axe should he provided. A well-made flat oil can, holding 4 ounces, that will fit into the jumper pocket completes the ordinary equipment where water holes are not drilled. In the latter case a piece of ¾-inch pipe with proper connection and hent at a right angle 1 foot from the end attached to the hose comes handy for blowing mud out of holes.

(TO BE CONTINUED.)

Mining Summary.

Specially compiled and reported for the MINING AND SCIENTIFIC PRESS.

ALASKA.

An extensive plant is being put in by O. H. Sleeper on Bear creek in the Cook Inlet district.

ARIZONA.

COCHISE COUNTY.

(Special Correspondence).—The Contact group of claims are 1½ mile west of Bisbee, in Warren mining district, and consist of twenty claims. The Higgings group, 1800 feet east of the Contact, was recently sold for $650,000. The Red Jacket, Wolverine and Clark groups have all been floated in Michigan within a month.

Bisbee, July 8.

The work of dismantling the Copper Queen plant at Bisbee was begun last week. this being the first move in the transfer of the reduction of Copper Queen ores from Bisbee to Douglas. The smelter will be kept in operation at Bisbee until the Douglas reduction works are ready to receive and handle the daily output from the various shafts of the Copper Queen mines. A great deal of work is yet to be done on the new plant, but it is expected it will be in operation January 1 next. Not only will all the machinery be taken away, but the old slag on which it stands will also be blasted out and put through the Douglas smelter, says the Review. A large amount of this slag will give good copper values, as it came from the old furnaces before later methods were adopted to save the ore values.

GILA COUNTY.

Superintendent E. H. Benson, of the Black Warrior mine, near Globe, closed down the works last week in order to put in a water-jacket furnace of 60 tons daily capacity. The matting furnace will not handle the product to be smelted, the ore from the new opening in the mine having changed and the precipitates from the leacher having increased. It will be two months before they are ready to resume. In the meantime a few men will continue work in the mine

At the Old Dominion mine at Globe development and construction work is progressing. The four-compartment shaft is down 250 feet. The foundations for the smelter are being built and boilers are being set up at the new shaft. All the buildings have been wired for electric lights. The stations in the mines are also to be electrically lighted. The present smelter is making the usual output of copper. Coke shipments have resumed.

GRAHAM COUNTY.

The Clifton Copper Era says the Arizona Copper Co. seems to have entirely recovered from the effects of the recent strike, and are working full handed at all their mines. They are running three furnaces and all of their concentrating tables. ——The Sierra de Oro Co. have begun development of their group near Clifton. They employ American miners and are working three eight-hour shifts.——The Shannon Copper Co. are running full handed at their mines, and also have their smelter and concentrator plant in operation.——The Standard Co. made a shipment last week, the first since the strike.

MOHAVE COUNTY.

(Special Correspondence).—The Daggett property is opened out with a 100-foot shaft on a small vein of ore carrying gold and silver values. Intentions are to sink the shaft 100 feet deeper.

Shipments of raw ore from the Samoa mine continue.

J. Carroll, at the old Juno mine, is sinking on the vein.

L. Hoffman is developing the Paymaster mine and shipping silver ore.

The Elkhart mine closed down on the 30th ult. and discharged its twenty-five men.

Dempsey & O'Dea are sinking a 100-foot shaft on their gold discovery, 9 miles west of Chloride.

Chloride, July 8.

The Elkhart mine, near Chloride, was closed down on the 1st. The management has stoped out all the ore above the 500-foot level, and no effort was made to continue deeper, says the Arrow. C. Barmore is superintendent.

The Mohave G. M. Co., operating the Leland and Mitchell mines, near Kingman, has taken on more men. As soon as their mill is finished the output will be increased.——The Treadwell group of mines will be in operation next week, says Superintendent J. Nevill.

The Homestake and Bi-Metal mines, 3 miles south of Kingman, have been sold to Manager S. E. Adair of a New York company for $75,000. The mine has been exploited to depth of 100 feet by shaft and tunnel, showing 25 feet of ore assaying $8 free gold. A mill will be built, says Manager Adair.

H. H. Smith, of New York, manager of the Great West mine, near Chloride, says he will put in a cyanide plant at the mine.

The shaft on the Copper Pride mine, near Kingman, is down 100 feet and the vein crosscut for 15 feet at that depth. They report having 3 feet of ore that averages 15% copper, $10 gold and a few ounces silver. The mine is owned by S. Butler and E. S. Osborne, and is under bond to B. Blanchard, manager of the Iron King mine in Yavapai county.

PIMA COUNTY.

Work is again under way at the Del Monte mines, 35 miles east of Tucson, in the Catalina mountains.

YAVAPAI COUNTY.

F. Dunham of Los Angeles, Cal., has bought the Katherin group of mines near Cralg for $60,000. Development work began this week.

At Congress three shifts of men are at work on the Alaska mine, and the shaft is down 85 feet.

Manager L. L. White, of the White G. M. Co., operating near Wickenburg (Maricopa county), says there are 1200 feet of development work done. The ore carries $15 per ton gold and is both free milling and concentrating, the ore body being 7 feet wide. The company will put in a mill next fall.

Superintendent C. B. Genung of the Oro Concentrating Co. reports development progressing on the Welcome group of mines in Weaver district, 1½ mile northwest of Stanton.

The Rigby M. & R. Co. have men at work preparing for the erection of their reduction plant at Mayer.

The Burlington M. Co., near Big Bug, will put in a hoisting plant this month.

ARKANSAS.

MARION COUNTY.

At the Climax mine, near Yellville, and owned in New York, they have been producing dirt that yielded from 15% to 20% zinc. Last week they opened up ore that will mill 40% metallic zinc. The mill at this mine, of forty tons capacity, will be enlarged.

CALIFORNIA.

AMADOR COUNTY.

(Special Correspondence).—The Shenandoah mine, 2 miles north of Plymouth, is down 1000 feet in the south shaft, the north shaft being over 500 feet deep. The two shafts are connected at the 500-foot level. The vein varies from 4 or 5 to 25 feet in width. There are several separate ore shoots in the vein. The values are in free gold and auriferous sulphides, principally galena. A new blower was recently put in by Superintendent S. K. Thornton to ventilate the workings below the 500 level. The company contemplates building a mill.

Plymouth, July 7.

At the Fremont-Gover mine, 1 mile north of Amador City, the gallows-frame over the Fremont shaft was finished last week and work on the foundation for hoisting machinery is being done. The mill is going up, says Manager A. Goodall. No rock is being mined at present, but considerable development work is being done. The air compressor has been repaired.

BUTTE COUNTY.

The sub-station of the Bay Counties Electric Power Co. at Oroville was destroyed by fire on the 5th inst. Three 800 H. P. transformers, value $4000, were lost. Twenty-five dredgers, supplied with power by the company, are temporarily idle as a result. A new sub-station was being built and is about finished.

CALAVERAS COUNTY.

W. Morehead, superintendent of the Crystal mine at Angels, says sinking continues in the Crystal shaft, which is down 620 feet.

Superintendent T. Kavanaugh of the Western Mines Co., operating at Rich Gulch, says he has men at work equipping the mine, machinery for which is on the ground. This includes a 6-drill compressor plant and water wheel, ventilating blower and a diamond drill outfit.

At the Lloyd mine at Central Hill, near San Andreas, operated by the Ophir M. Co., Superintendent F. Heath says he is putting in a boiler and other equipment. There is an incline 165 feet in depth, and this will be extended 200 feet deeper to tap the channel. A 6-stamp mill will be built.

At the San Domingo G. M. Co. mine at Dogtown, near Altaville, the tunnel was completed last week. It is 1100 feet in length and 20 feet deeper than the channel. The company has plenty of water for operating the mine, says Superintendent B. Thompson.——At the Bully Boy gravel mine, near Altaville, work is progressing. Two shifts are sinking a shaft to bedrock and are down 120 feet.

EL DORADO COUNTY.

The unwatering of the Havilah mine, at Nashville, is completed.

INYO COUNTY.

Superintendent Flint of the Tuber Canyon group, near Ballarat, reports the stamp mill and cyanide plant running steadily.——The Creed Co. will put in a mill.

KERN COUNTY.

Work will be resumed on the War Eagle mine, near Randsburg. A double-compartment shaft will be sunk, and as soon as sufficient ore is in sight to warrant it a 5-stamp mill and cyanide plant will be built.

Jensen & Hoffman are working on the LaCrosse claim, adjoining the Sunshine mine, near Randsburg, says the Miner. They have sunk a shaft 136 feet and are crosscutting.

L. D. Daves and J. J. Nosser have a lease on the Mabel S. mine, near Randsburg. They have a 14-inch ledge which assays $30. They are sinking on the ledge. The claim adjoins the Yellow Aster on the west.

MARIPOSA COUNTY.

Peregoy Bros. are doing development work on their claim, near Whitlock. They have put in a hoisting and pumping plant. The shaft is showing a 3-foot ledge of pay quartz.

Wood & Maddox have bonded one of the Weston group of claims east of the Imperial mine, near Whitlock. It can be worked from a tunnel which is in 40 feet.——J. Teats has bought the two stamp mills of S. J. Johns and intends milling his ore from the Spread Eagle. The tunnel of the Spread Eagle is in 435 feet.——The Hayseed mine, owned by W. Dolph, resumed operations last week. The second and third levels will be run 100 and 150 feet farther, respectively, and raises driven.

The Diaz copper mine on Bear creek, near Indian gulch, is being worked again.

MONO COUNTY.

Superintendent Pierce, of the Crystal Lake G. M. Co., operating the May Lundy mines at Lundy, says he has seventy men at work. The tunnel is in 3440 feet.

NEVADA COUNTY.

The 300 H. P. compressor put in at the power house of the North Star M. Co. at Grass Valley is in full operation, says Manager A. D. Foote, and, with this running, they are developing a total of 800 H. P.

Fire destroyed the entire upper works at the Seven-Thirty mine, on Deadman's Flat, near Grass Valley, on the 3rd inst., also the timbering for 40 feet down the shaft. The origin of the fire is unknown. J. J. Riley owns a controlling interest.

PLUMAS COUNTY.

G. Gruss, operating the Genesee mine near Genesee, says he is putting through his 15-stamp mill an average of sixty tons per day. Between the slate and the porphyry walls the lode matter consists of a network of small veins, and the entire mass is being quarried and put through the mill. To recover the loss in the tailings, concentrators will be put in and the mill further enlarged this summer.

SAN DIEGO COUNTY.

Manager L. N. Bailey says the company will resume operations in the Kentuck tunnel, between Banner and Julian, this month.

Superintendent Morrissey reports work going ahead in the Alpha mine at Banner and he is driving a level from the 300-foot tunnel to the North Star shaft.

SHASTA COUNTY.

Superintendent C. M. Osborn has men at work on the Mount Shasta May Blossom mine near Bully Hill (Winthrop P. O.)

In Shasta county the two smelters in operation are treating 25,000 tons of copper ore per month, the Mountain C. Co. at Keswick 20,000 tons and the Bully Hill M. & S. Co. at De Lamar 5000 tons. The De Lamar smelter will be enlarged. Besides working its own ore, the Mountain C. Co. treated ore from seventy-six shippers in the county during 1902. One other smelter is going up, the Great Western Co. at the Afterthought group at Bella Vista, and one other is proposed at the Balaklala group at Kennett, says the Redding Free Press.

SIERRA COUNTY.

The Lassiat G. M. & M. Co. has been incorporated at Poker Flat, near Downieville, by J. B. and R. Lassiat, F. P. and A. Roddy and F. Humbert.

SISKIYOU COUNTY.

The McKean mine at South Fork of Scott river, near Callahans, has been shut down for three months, to make improvements for more economical working. Water power will be used in place of steam for the compressors, as there is abundance of water available. The company has a cyanide plant.

The Brown Bear and Hammer Co. claims at Hamburgh Bar, on the Klamath river, from 3 miles below the bar to 1 mile above, have been bonded to L. L. Rees, C. Tucker, J. S. Perky and B. A. Cardwell of Denver, Colo. They will build a 14-mile flume from Scott river. G. Whipp and B. A. Cardwell have bonded the Offield claim, opposite Hamburgh, on the Klamath river.

At the Drummer Boy mine, near Yreka, development work is progressing with a few men preparatory to putting in a stamp mill. Electric power will be used.

TUOLUMNE COUNTY.

A new strike is reported in the Mount Jefferson mine at Groveland, on the 500 level. The same shoot was cut not long since on the 400 level.

The two-compartment shaft on the McAlpine mine, 5 miles southwest of Big Oak, is now down 250 feet. At the 200 level a crosscut will be driven to the vein, which will be explored by drifting. The mine is on the mother lode and has a large vein.

The Mohican mine, on the Tuolumne river, 5 miles southeast of Groveland, and near the Buchanan mine, is running its 5-stamp mill steadily. The mine is developed by tunnels, but a hoist is being put in in a station in the lower tunnel, and a shaft sunk on the vein.

Wm. Floyd is developing the Garfield mine, 1½ mile south of Carters. This mine is said to be on the Providence vein.

The Cosmopolite mine, near Groveland, is equipped with a steam hoisting plant and air compressor, and a mill is in contemplation by the management. In its early history the Cosmopolite was worked as a pocket mine and as such produced largely. It is now considered that the low-grade ore has become available by reason of improved methods and modern knowledge, and will pay to work. H. Argall is superintendent.

Operations in four of Tuolumne county's mother lode mines are suspended, as the miners of the Jumper and Golden Rule mines at Stent and the Santa Ysabel and the App mines on Quartz mountain quit work, because the companies refused to discharge non-union men. The strike affects 300 men. In addition to this, the union has demanded of all the mine managers in the jurisdiction of the Tuolumne union a new wage scale, which is an increase of 25 and 50 cents per day over the rate now paid in most cases. The scale is as follows: Machine men, chuck tenders, hammer men, timber men and pump men $3 a day, and all other skilled laborers not less than $3; muckers, carmen and top laborers, $2 50 a day; millmen and engineers and machinists, $3 50. In the case of machine miners and timber men the new scale is the same as before.

The Tuolumne County Dev. Co. have started operations on the Blue Jay and Jack Rabbit mines, near Carters, and adjoining the Providence mine on the south.

J. McCormick has bought a one-fourth interest in the Eureka quartz claim, at the head of the south branch of Whisky gulch, 2 miles from Jacksonville.

TRINITY COUNTY.

(Special Correspondence).—At the Dorleska mine a strike has been made on the fourth level at a vertical depth of 300 feet. The ore, where first struck, was 4 feet wide, and included a streak of 10 inches of $100 ore. The ore body has widened to 10 feet, then to 15, and on July 1 the walls were 29 feet apart, 20 feet of which is a good grade of milling ore. This ore body has been worked on the third level, 120 feet above, but it was not expected to show such width. On the third level it averaged 10 feet in width, and at its greatest dimensions was 17 feet wide. The Dorleska recommenced sinking the shaft from the third level at depth of 180 feet December 23, 1902, and went to depth of 317 feet. A station was cut and a crosscut west reached the first contact at 45 feet and the second contact at 107 feet A drift north was started 89 feet west of the shaft and the ore body cut in the north drift 75 feet from the crosscut. Ore of milling grade is being taken from another development on the Dorleska, in a north branch of tunnel No. 2, nearly 1000 feet north of the shaft. This is a new source of ore supply. The Dorleska mill commenced working June 3, 1901, and with the exception of four months, when it was shut down by heavy snows—from February 25 to June 19, 1902—it has been running continuously to date. The mill has been enlarged twice, and the developments of the past month, it is stated, add two years supply of ore at the present rate of consumption. The addition of another 5-stamp battery is under consideration, and will probably be made this season. About 4000 tons of ore had been milled to July 1, producing over $100 000. An average of forty men are employed at the Dorleska throughout the year, and

in the summer season, with contractors for wood and timber, the number reaches sixty. During July the company's sawmill will cut lumber and timbers for another year. Union Consolidated G. M. Co. of Los Angeles, owners; H. Z. Osborne, president; M. H. MacIlwaine of Dorleska, superintendent.

Dorleska, July 7.

The ledge in on the second tunnel in the Globe mine, in Canyon Creek mining district, near Weaverville, has been struck at 800 feet, says the Trinity Journal. Heretofore the mill has been run by steam and could only he used five months a year. Compressed air will be used hereafter. Superintendent R. A. Skinner has twenty men at work. It is proposed to enlarge the plant.

YUBA COUNTY.

(Special Correspondence).—A. H. Elftman, one of the directors of the Miller M. Co., is here from Minneapolis, Minn., and proposes having a resumption of work next month.

Brownsville, July 8.

Work on the Yuba debris barriers, near Marysville, is again under way. They have twelve men at work stripping the quarry for barrier No. 1. A ditch 1 mile long has been dug.

COLORADO.

BOULDER COUNTY.

A. S. Wise, manager of the Black Swan M. Co., composed of Meadville, Penn., men, has resumed, and is overhauling the mill. The group is between Sunshine and Salina, containing large veins of low-grade ore. The mill is equipped for concentration and will have cyanide added for saving the values in the tailings.

The Rocky Mountain Fuel Co. began operations last week toward sinking a new coal mine on the Wanaka place east of Louisville. The hoisting apparatus is in place.

CLEAR CREEK COUNTY.

(Special Correspondence) —T. B. Crow of Idaho Springs will add concentrating tables and crushers to his new mill.——F. F Reed, manager of the Bonita mill, states he is getting all the ore he can handle and has had to increase the capacity. He has thirty stamps and a 15-ton cyanide plant, and if the cyanide plant is successful will increase to forty tons. —— The Idaho Springs M. & R. Co. have overhauled their mill and put in additional jigs. Work has resumed full handed.

Idaho Springs, July 5.

(Special Correspondence).—J. R. Elgan, manager of the New Era Co. at Freeland, 5 miles southwest of Idaho Springs, has opened a 3-foot vein of $50 smelting ore. Forty men are employed on the property.

Freeland, July 5.

(Special Correspondence).—G. W. Teagarden, manager of the St. Paul G. M., S. T. & D. Co. in East Argentine mining district, is driving two tunnels. His company will put in a water power plant.—— The main tunnel of the Red Oak mine is in 3000 feet. At the 2500-foot mark they have started to drive a crosscut and expect to cut the Astor vein. Two cars of $100 ore are being shipped from the Sunburst mine each week.

Georgetown, July 5.

The Manhattan Union M. Co. has been organized to work the Kittie Ousley, Big Chief, El Dorado, Mound Builder, Lead Island and Rosalie group of lodes in East Argentine district, adjoining the Waldorf, near Georgetown, by H. W. Preston, D. W. Barkley and E. J. Wilcox. Development machinery will be put in.

The Central tunnel of the Big Five Co. at Idaho Springs will be driven ahead 5000 feet by contract at $10 per foot, the contractor to he furnished with machine drills, steel, air and ventilating pipes, rails and ties, and compressed air. The contract calls for a tunnel 5 feet wide by 8 feet high in the clear, and is in 1800 feet.

Manager J. H. Towne has added another location to the group of claims he is developing for the Indiana G. & S. M. & M. Co. on McClellan mountain, near Silver Plume, making eight in all, besides a tunnel site and millsite. The vein shows values in gold and silver. This lode will he reached in 500 feet by the adit tunnel being driven on the Indiana lode.

CUSTER COUNTY.

J. P. H. Callahan and R. E. Myers of Westcliffe have a bond and lease on the King of the Carbonates group, near Westcliffe, for $50,000.

DENVER COUNTY.

J. B. Grant, chairman of the executive committee of the American S. & R. Co., estimates the damage at the Grant & Globe smelters of that company at Denver, caused by the unexpected strike of the employes at $25,000. All hut two of the eleven furnaces in use were "frozen," and the ore will have to he cut out before the furnaces can again be used. Manager F. Guiterman of the Globe smelter expects to have operations under way again next week.

DOLORES COUNTY.

S. Newhouse of Salt Lake City, Utah, will equip his group of mines, near Rico, with a concentrator.

EL PASO COUNTY.

An attempt was made to blow up the plant of the Colorado Springs Electric Co. on the 5th inst. with dynamite. One hundred and fifty sticks of dynamite were piled alongside the north end of the buildings and a fuse lighted. The explosion of one stick distributed the other sticks over a radius of 200 feet, saving the building and the lives of seventeen employes. The glass in all the northern windows was broken and fires started, which were quickly put out. The company furnishes power to the Standard mill of the United States R. & R. Co., where a strike has been declared by the Western Federation of Miners.

GILPIN COUNTY.

J. H. Wilson, W. L. Shull and C. C. Worrall of Denver have incorporated the Onoko M. Co., to work on the Steady Income group of mines, near Russell Gulch. On the Paola mine they have put up a hoisting plant. The company also owns the Onoko group of mines.

E. S. Moulton of Central City has taken a lease on the Hillhouse mine, near Russell Gulch.

At the Foote & Simmons mine, on Bobtail hill, near Central City, the company will put in a 10x12 hoist and an 80 H. P. boiler, and will use electric drills. The shaft is down 600 feet and the company intends to sink down to a depth of 1000 feet. S. Mellor is superintendent.

The Cadillac M. & M. Co. have a lease and bond on the New Hampshire group of claims, at the head of Lump gulch, and have started operations. The ore will be tested at the Stanley mill, near Gilpin, owned by this company.

During the month of June the shipments of smelting and crude ores, concentrates and tailings from the Black Hawk depot to the smelters and mills made a total of 235 cars, or 4700 tons.

T. George of Denver has a lease and bond on the Howard tunnel group, up Clear creek, in Enterprise district, near Central City.

The Nevada Con. G. M. Co., operating the King, Lamberson & Warren and Oronoake mines on King flats, near Central City, has carpenters putting up buildings for a lead concentrating plant, says President T. Marx. The mill will have a capacity of fifty tons per day. Sinking has been resumed at the Pierce mine at Central City by the English company. The shaft will he put down an additional 100 feet, making it 400 feet deep.

GUNNISON COUNTY.

The Keystone mine, 3 miles above Crested Butte, is to be operated this summer. This property carries silver, lead, zinc and copper values, says Superintendent H. Schraft, who has cleaned out the drifts preparatory to doing further development and taking out ore. A mill is in contemplation.

The Gunnison M. S. & R. Co. has been incorporated at Gunnison. J. J. O'Brien, J. T. Cavanaugh, F. W. Otto, F. A. Whitney and W. H. Baker. The company will put up works for smelting, concentrating and reducing ore.

The Blistered Horn tunnel near Tincup, which is being driven under the Jimmy Mack mine workings is in 400 feet, and will be extended 1100 feet farther. The Jimmy Mack vein carries high-grade copper values; also values in silver and lead. The Brunswick M. Co. of New York and New Jersey is doing the development work.

The West Gold Hill M. Co. will resume operations next week on the J. B. Sellers group on West Gold hill, near Tincup.

LAKE COUNTY.

At the Ibex combination at Leadville 250 tons of ore a day are being mined. Shafts Nos. 2 and 3 are furnishing most of the ore. At No. 4 shaft sinking is going on to complete connection with the Yak tunnel. No. 3 shaft, down 800 feet, will be sunk another 450 feet.

Manager Strong says the Banker mine, near Leadville, will be reopened.

The Fryer Hill M. Co., operating at Leadville, will increase their output until they are shipping 1000 tons a day.

The output of Leadville district for June was 80,000 tons of all classes of ore—this, too, with a large amount of development work under way.

LA PLATA COUNTY.

The Neglected mill, near Durango, is in operation, with a capacity of treating 100 tons daily. They amalgamate before and after concentration. The grinding is done with Chilean mills, the pulp passing over amalgam plates and thence to Frue vanners, the tailings passing over another set of amalgam plates below.

MINERAL COUNTY.

The ore output of Creede district for 1903 to July 1 is as follows:

Month.	Tons
January	5,283
February	5,788
March	7,072
April	5,715
May	5,645
June (estimated)	7,000
Total	36,503

OURAY COUNTY.

A. Van Horn of Ouray has bought the Snowflake mine in Red Mountain district, near Vanderbilt, and is moving up the Paymaster hoist with which to unwater the shaft and start development, says the Standard.

PARK COUNTY.

The placer ground covering 490 acres, near Tarryall, is being worked, says J. H. Weigert of Colorado Springs, part owner. An hydraulic plant will he put in.

The Almaden M. Co., near Tarryall, is preparing to start to work on a 1500-foot tunnel.

SAN JUAN COUNTY.

Preliminary work has been started on the Stony Pass M. Co.'s group, in Stony Pass section, near Silverton.

The Four Metals M. Co, which has a bond and lease on the Lackawanna group, on Blair mountain, near Silverton, has cleaned up the upper workings of the mine preparatory to regular operation. The Lackawanna group is of five claims and contains low-grade silver-lead ore.

The Sturgeon & Gordon lease on the Spotted Pup mine, near Silverton, having expired, operations will be continued by the Contention M. Co., owners. The ore streak is 20 inches wide of high-grade gray copper ore. The Contention Co. will resume work on all of the claims of the North Star group.

The Kendrick & Gelder Smelting Co., the Oliver Reduction Co. and the Paradox Copper-Gold M. Co. have been consolidated at Denver as the San Juan S. & R. Co. It is proposed to build the tramway and additional reduction works. Included in the properties of the San Juan Co. are three groups, one of thirty-four claims in Prospect basin, one of seven claims in Picayune gulch, one of four claims in Burroughs park, and the group of six claims at Silverton. In addition there is the Henrietta tunnel site. The smelter is of 150 tons daily capacity, and is on the Silverton group. F. C. Kendrick is general manager.

SAN MIGUEL COUNTY.

Superintendent G. Land of the Keystone Hydraulic M. Co., operating near Telluride, says he has twenty men at work on eight-hour shifts. Another giant will be put in. Electric lights have been placed about the gravel pit and other workings. Sluicing will continue as long as the water holds out.

SUMMIT COUNTY.

The Ætna and Vesuvius mines, on Fletcher mountain, near Kokomo, will be started up, says Manager V. E. Myer. Both properties have gold quartz.

TELLER COUNTY.

The Cripple Creek Times says, considering the time lost on account of rainy weather during the month and the temporary close-downs in many of the mines, the tonnage of the district for June was higher in proportion than May:

	Tons.	Total Value.
Smelters	12,000	$720,000
U. S. R. & R. Co.	20,000	500,000
Telluride	5,100	153,000
Economic	3,800	83,600
Portland	7,000	210,000
Dorcas	2,900	94,250
Globe	400	1,600
Gillett	450	1,237
Totals	51,650	$1,763,687

The leasing of the Stratton estate, completion of the drainage tunnel, the tax decision and the geological survey are expected to influence important increases in the output of the district.

The Empire State Con. M. Co. is reported closed down. The company owns the groups formerly owned by the Arrow G. M. Co. and Orphan G. M. Co., in all twenty acres on Bull hill, Cripple Creek. N. B. Williams is president.

A complete cyanide mill is being built on the ground of the Doctor-Jack Pot Co., on Raven hill, Cripple Creek, that will treat the low-grade oxidized rock hoisted through the Ingham incline shaft. The operators are Oastler, Tomlinson and Pender brothers. The mill will have a capacity of thirty tons per day.

The Tunnel M. & L. Co., which secured the first lease granted by the Stratton's Cripple Creek M. & D. Co., are putting in additional machinery at the Abe Lincoln mine, up Poverty gulch, near Cripple Creek, says Superintendent W. Swanson. Sinking the shaft another 100 feet has started. While they are required to sink at least 100 feet, they are not restricted as to depth, and can sink to and mine ore at any depth. Five other leases have been granted, says Manager W. G. Rice, covering portions of the Pauper, Monitor, Midget, Silver State and Colorado King claims, on Gold and Globe hills. W. G. Morse, M. Welch and A. C. Mansfield of Cripple Creek, on blocks No. 85 and No. 89, will put in development machinery.

Manager W. E. Lloyd of the Sioux Falls & Cripple Creek M. & Dev. Co., says preparations are being made to put up a cyanide mill on Spring creek at the foot of Copper mountain, near Cripple Creek and below the Fluorine mine, operated by the company.

The Mollie Kathleen mine, adjoining the Gold King on Womack hill, near Cripple Creek, has been bonded and leased for $75,000 to the Creston Big 8 M. Co., of which H. C. Boll is manager. The Mollie Kathleen is developed by a two-compartment shaft 710 feet in depth.

Diamond drills have prospected the ground of the St. Patrick M. Co. at Victor, and a drift is being run north on a vein at a depth of 500 feet. The St. Patrick mine is owned by Clark & Co. of Scotland.

IDAHO.

BLAINE COUNTY.

Superintendent F. S. Adams of the Rosetta M. Co., operating on Little Smoky river, 35 miles from Hailey, says he has fifty men at work. Their sawmill is cutting lumber for a mill, bunkhouse and other buildings. A laboratory will be put up, and also a 20-stamp mill. Ten stamps are being set up to start with. The Rosetta Co., operating the Williams group of claims, near Hailey, has completed a road up Williams gulch to the millsite.

Manager M. H. Lipman says work on the tunnel to tap the Bullion series of veins, near Hailey, will go ahead. Power drills will he used.

BOISE COUNTY.

A. C. Gallupe, manager of the Golden Rod M. Co., operating on Mineral hill, near Placerville, says the development consists of a shaft 130 feet deep on the Don Carlos, adjoining the Mineral Hill claim. A tunnel driven in on the Mineral Hill 1100 feet is within 20 feet of the shaft, though 64 feet below it. Connections will be completed this month. The 5-stamp mill has been overhauled and is again in operation. It will be increased this season to twenty stamps. C. M. Corns is superintendent.

IDAHO COUNTY.

(Special Correspondence) —The Jumbo mine shipped out from Buffalo Hump last week $5000 in bullion as the result of twenty-five days run with their 4-stamp mill. The ore bodies on No. 3 level, 515 feet depth, are reported improving. The additional 10-stamp mill is being set up, and is expected to be in operation by July 15th.

The Cracker Jack mill capacity at Buffalo Hump is being increased. The mortar and additional five stamps are on the ground, having been shipped in via Stites, the railroad terminus.

Moose Creek Placers Co., at Newsome, has made its third partial cleanup in thirty days, yielding $6000 from this ground in that time. Returns from the U. S. Assay Office at Boise gave the fineness of the two former cleanups at 940 and 937½. It is proposed to increase their equipment and extend their ditches. C. P. Richardson of Newsome is president and manager.

Lewiston, July 6.

The Rainbow G. M. Co. has been incorporated to operate the Harrisburg group of three claims in Thunder Mountain district, near Roosevelt. R. F. Agnew, W. F. Lybrook, T. C. Downing, A. C. Buxton and E. M. Evarts of Michigan, with G. Wertz of Boise, who is manager. The three claims taken over by the company are on Rainbow mountain and near the Fairview. Operations have begun. A contract has been let to drive a crosscut tunnel of 300 feet. It is expected the ledge will be struck at depth of 150 feet. It is intended to put in a 20-stamp mill this fall, which will he built 2000 feet from the mine, and an aerial tramway transport the ore from the mine to the mill.

Work has resumed on the Big Buffalo group in Hump district, says C. Sweeny of the Buffalo Hump M. Co. Experiments will be made with a cyanide process to handle the ores. For the present work will be on the tailings, and if the system is successful with them it will be used to treat the raw ores. There is a stamp mill already up. They will drive a drift from the Oro Fino ground 4000 feet along the vein, which will give a depth of 500 feet.

LEMHI COUNTY.

C. G. Reiter and F. R. Abbey of New York and C. Wright of Salmon City have

a bond on the Haldee mine, near Leesburg, and will start development work. This group consists of five full claims. The vein is 10 feet wide, with values in gold and silver.

The coal discovery made near Salmon City is being developed by F. M. Pollard, the owner, who reports having 13 feet of merchantable coal in two veins, with a stratum of 16 inches of shale between.

The Edmund group of mines on Little Deer creek, near Blackbird, has been sold to the Edmund Quartz M. Co. of New York and Boston men. The Edmund mines consist of four quartz claims and 160 acres of placer ground. There are 500 feet of tunnels driven, showing a 6-foot vein of free-milling gold ore. A new tunnel has been started which will cut the ore 100 feet deeper than the present workings, and machinery for both extraction and treatment will be put in.

LEMHI COUNTY.

R. L. Edwards, manager of the Kittie Burton G. M. Co., says work on the Ulysses mine at Ulysses is progressing, and they will put in fifteen additional stamps at their mill, which will give the mill a total of thirty stamps, which will handle ninety tons daily. Grading for the addition to the mill has begun.

SHOSHONE COUNTY.

The owners of the Golden Chest mill, near Murray, propose to build an entirely new mill, which will have fifty stamps, and a cyanide plant. They now have twenty stamps.

The Beartop silver-lead group was sold last week, including the Simmons placer and water rights, to G. E. Myers, C. C. Groesbeck and E. Brucker of Toledo, O., for $250,000.

The International Mines, Ltd., has been incorporated by J. White, J. L. Clark, E. S. Wyman, W. Graham and M. Baumgartner of Burke to operate a group near the Hercules mine, above Burke.

WASHINGTON COUNTY.

The Short's Bar placers, 1 mile above the mouth of the Little Salmon river, near Weiser, have been sold to the Pittsburg M. Co for $12,000. Hydraulic equipments will be put in and a ditch built to bring 1000 inches of water to the ground. Two giants will be operated.

INDIANA.

The Central Oil Co. of Boston, Mass., has sold some of its oil leases in Madison and Delaware counties to the Ohio Oil Co., including 140 wells on the basis of $1000 per barrel capacity. The deal as a whole aggregated $300,000.

KANSAS.

NEOSHO COUNTY.

A zinc smelter company has been incorporated to build a plant at Chanute. H. Hess and J. Rauer, of St. Louis, Mo., with F. W. Stuecke, of Girard, Kan.

MICHIGAN.

HOUGHTON COUNTY.

The Champion mine, near Painesdale, has its fourth head running as regularly as rock can be furnished it by the mine. It is impossible for the mine to make a full showing in rock output until the 100-drill air compressor is completed, says the News.

The Osceola mine, near Calumet, for the first half of 1903 produced 7,000,000 pounds of refined copper. The average price received for the first five months was 13¾ cents; and the June average has been 14½ cents. The entire cost of mining, milling, smelting and marketing is reported at 9½ cents per pound. Seven heads will be kept running steadily, and daily rock shipments average 3500 tons.

The hoist for Baltic shaft No. 4, near Houghton, is being set up and is expected to be ready to go into commission next week.

The output of the Quincy mine at Hancock for June was 1902½ tons of copper.

The Winona mine at Winona for June produced eighty-four and one-half tons of copper; total output since production began in January, 1,007,000 pounds.

The News says, the Atlantic mill, near Houghton, stamped on June 30 Atlantic rock yielding 30,300 pounds of copper. This is the heaviest yield for a single day since the mill has been running, the usual number of stamps being dropped.

KEWEENAW COUNTY

Machinery for the hoist at No. 4 shaft of the Mohawk mine, near Allouez, is being set up. The hoist has a capacity to depth of 4000 feet and is a duplicate of the hoist being put in at No. 4 shaft of the Baltic.

The drain shaft at the Allouez mine, near Allouez, in sinking for the Kearsarge lode, struck the ledge at depth of 41 feet. The work of sinking the main shaft was discontinued temporarily on account of a rush of sand and water, until this drain shaft alongside of it could be sunk to the ledge through the quicksand. Sinking of the main shaft has resumed.

ONTONAGON COUNTY.

It is reported at Mass City the Mass mine management is decreasing the number of drills in use and also the number of men at work.

MISSOURI.

JASPER COUNTY.

The Seven Devils M. Co., operating in South Carthage camp, started a shaft last week for a known bed of ore at the 70-foot level and struck good ore at 6 feet. The company has heretofore taken out ore at the 25 and 40-foot levels.

The Bald Eagle mine, on the Plutocrat lease, southeast of Webb City, has been sold to W. McCulley of Macon, Mo., for $15,000.

The Par Value Zinc and Lead Co. have taken over the Read lease of six lots, near Duenweg, under the supervision of J. G. Dinkelbihler. Cincinnati, O., men are interested. Prospecting will be started at the shaft, formerly known as the Big 20 of Carthage. A 50 H. P. plant is being built.

LEWIS COUNTY.

At the Bunker Hill mine at Bunker Hill, owned by A. Hardy of Webb City, the mills are being repaired. A new shaft will be sunk on seven more lots of the same tract.

NEWTON COUNTY.

The Mears M. Co., who hold a lease on N. J. Parrot's land, 2 miles southeast of Granby, report a strike last week, the drill cutting into ore at 220 feet.

MONTANA.

The metal output for Montana for 1902, as shown by the annual report of the director of the mint, just issued by B. H. Tatem, assayer in charge of the United States assay office, in Helena, was $46,961,-167, a decrease of 22% from 1901. The decrease was due to lower prices for copper and lead. The production for 1902 was as follows: Gold, $4.400,095; silver, $16.622 285; copper, $24,606,038; lead, $332,747. Tatem's report shows that the copper ores of Butte carry more gold than formerly.

FERGUS COUNTY.

The Judith M. Co. has been incorporated by A. Hayden, A. P. Pendleton and A. W. Bulkley of Chicago, Ill. Lewiston will be the principal place of business. The company owns the Judith mine near Lewiston.

GRANITE COUNTY.

In Antelope district, near Phillipsburg, work is again under way on the Mountain Ram group of mines, owned by J. A. Murray and S. F. King of Butte. J. Dixon is superintendent. The Mountain Ram group (the Antelope) is a gold property. It is proposed to put up a cyanide mill.

JEFFERSON COUNTY.

Mulvahill & Ely, lessees of the Daly group at Wickes, are shipping three cars a week of high-grade ore and have several hundred tons of second-class ore on the dump. Their mill, having been enlarged to 100 tons a day, resumed last week.

J. H. McCabe has sixteen men at work on his group near Corbin, and will sink two shafts 500 feet to develop bodies of copper ore. He has located fifty claims in the Corbin-Wicks district.

MADISON COUNTY.

The Little Kid mine, near Norris, has been bonded by Jardine and Livingston men. There is a 10-stamp mill, a 20-ton Bryan mill and sawmill on the property, and it is intended to build a 100-ton concentrator. Negotiations are reported in progress for a lease and bond on the Saginaw.

S. Newhouse of Salt Lake City, Utah, controlling the Revenue group of mines at Norris, says he will build a cyanide plant of 100 tons daily capacity. J. Dederichs is superintendent. In addition to the milling ore, they have some ore which is shipped direct to the smelter.

Manager C. E. Damours of Virginia City says the Damours M. Co. has been organized to develop the Bryson-Damours group of claims in Summit district, near the head of Alder gulch, near Virginia City.

One mile above Pony, in Pony gulch, the Zenith M. Co. of Butte, J. Hilchen president, is operating the Big Timber mine, with P. A. Gamer manager. The mine is being developed by a tunnel.

C. T. Wiedman has a lease on the Oregon mine, near Pony. It is intended to put a 5-stamp mill on the mine, work to begin this month.

The No. 2 dredger of the Conrey Placer Co., near Ruby, is in operation.

RAVALLI COUNTY.

The Boulder Creek Hydraulic M. Co. have been hauling in lumber and supplies to their diggings near Hamilton. They are putting in a sawmill and engine and will cut their own lumber for flumes and buildings. Boulder creek is south of Hamilton across the range east of the Orr-Kendall mine. The company have 3 miles of the main creek and 3 miles of side gulches. A. Koehler is superintendent. The company expect to finish the hydraulic plant this season in time for a full run next year.

SILVER BOW COUNTY.

Improvements are being made at the Butte Reduction Works, owned by W. A. Clark at Butte, the most important of which will be a copper refinery. The refinery will occupy the site formerly covered by the timber-framing plant. Adjacent property has also been bought.

The Reins C. Co., composed of Butte and Pittsburg, Pa., men, operating the Combination mine at Butte, have started to sink the main shaft another 500 feet, which will make the shaft 1000 feet deep.

It is reported W. A. Clark will reopen the Black Rock mine of Butte after a lapse of fourteen years. It is proposed to sink a shaft to 1000 feet depth in hope of uncovering a copper deposit. In former years the Black Rock was a silver mine.

The Nipper mines case, a suit involving a portion of the Nipper lode, near Butte, has been called for trial.

NEVADA.

CHURCHILL COUNTY.

The Territorial Enterprise says a mining rush has taken place to Pedro City, 12 miles southeast of Fairview and 6 miles east of Eagleville. The ledges have been traced for some distance at surface and locations staked off. There are said to be twelve ledges running parallel with each other, covering 1200 feet in width, and two of the ledges are 40 feet wide, the others averaging from 1 to 10 feet. Gold, copper and silver values are found. It is in a rugged country, barren of timber and vegetation, and the nearest water a distance of 8 miles.

ESMERALDA COUNTY.

The Tonopah-South Gold Mountain M. Co. has been incorporated to operate in Gold Mountain district, 4½ miles southwest of Tonopah; D Wilson, J. T. Fogarty, E. Loessel, T. R. Bannerman, C. A. Clinton, A. J. Martin, C. T. Grimes and J. S. Bannerman are directors. The company owns fifteen claims extending southeasterly from the Milbrae Co.'s claims.

C. H. Elliott has bonded the Mary mine at Silver Peak for $75,000 for Salt Lake parties. The property consists of one mineral claim and a tunnel site, equipped with a 10-stamp mill and cyanide plant.

LANDER COUNTY.

The New Pass M. Co. are putting in a pipe line and will build a stamp mill, says Manager W. Snyder of Salt Lake City, Utah. The ore averages $10 per ton in gold.

LYON COUNTY.

The company operating the North Rapidan mine, at Como, has authorized Manager E. Boyle to accede to the demands of the Lyon County Miners' Union to increase the pay to $4 for an eight-hour day, and driving the drain tunnel was resumed this week, says the Enterprise.

NYE COUNTY.

G. Wingfield, J. P. Hennessy and A. Thompson have a bond on the Workman group of mines at Cloverdale, 50 miles northeast of Tonopah, for $30,000. The pay shoot is 15 inches wide in an 11-foot ledge and carries an average of $50 a ton in values. A shaft will be sunk, says Superintendent Thompson.

Wingfield & Hennessy, with J. A. Meith, have bought a group of claims at Lone Mountain, near Tonopah.

F. B. Work, superintendent of the Newhouse properties at Hannapah, reports machinery on the ground, including a pump having a capacity of fifty gallons a minute, to handle the water struck on the 250-foot level. The south crosscut from the 250-foot level is in 55 feet and has cut the foot wall of the vein.

U. B. and G. H. Curtis have bought a group of seven claims at Lone Mountain, near Tonopah, between the O'Meara-Lynch and the Tonopah Alpine groups, and have incorporated the Alpine-Eagle M. Co.

The Tonopah-Ray M. Co. has been incorporated by L. C. Ray, C. H. Hammond, J. S. Cook and A. Kunze, the last named being general manager. The property of the company embraces eight claims at Ray; the main office is in Chicago, Ill. Work has been begun on the Enterprise claim, which shows 5 feet of ore.

T. S. Ford of Grass Valley, Cal., has bought five claims at Lone Mountain known as the Battleax group, which adjoins the Lone Star group on the west.

The Tonopah-Belcher M. Co. has been organized by J. C. Gladden, F. H. Lathrap, C. E. Hudson and J. W. Briggs, to operate the General Thomas group at Lone Mountain, near Tonopah. On the General Thomas claim, at depth of 60 feet, a 4½-foot ledge has been opened up.

Reno men have bought a group of claims adjoining the Alabama-Tonopah and organized the Esmeralda M. Co. to work the property.——The Tonopah-Eureka M. & Dev. Co. has been incorporated to work a group of five claims east of the Tonopah-Great Western. L. L. Mushett is president and J. Galinger secretary.

The Belmont and Minta groups of five claims, which adjoin the King-Tonopah mine on the north, near Tonopah, have been sold and the Utah-Tonopah M. Co. has been incorporated to work them; J. L. Butler, G. A. Whiteford, A. P. Davis, S. Garrison, F. L. Van Duzer and H. C. Marcus. The head office will be in Tonopah.

The Lone Mountain Syndicate has been organized to work a group of seven claims on the western slope of Lone mountain, 2 miles south of Barrel Springs, near Tonopah. There are two ledges, bearing values in lead, silver and gold. R. P. Dunlap, W. J. Douglass, W. H. Foster, F. Thorn, T. G. Elgie, H. Fletcher and W. J. Stoneham are incorporators. They claim the ore can be hauled to Candelaria for $8 per ton.

STOREY COUNTY.

The shaft of the hoisting engine at the St. Lawrence mine in Butte City, near Virginia City, was broken last week and the miners have been laid off for six weeks.

Repairs to the hoisting engine at the main shaft of the Con. Cal. & Virginia mine at Virginia City were completed and operations resumed this week. The superintendents' report for the week ending July 4 show: At the Hale & Norcross the tunnel was advanced 13 feet; total length, 3742; formation, diorite, with slight seepage of water. In the Sierra Nevada, at the S. N., M. & Union shaft, 1600-foot level, the north lateral drift, started from the joint west crosscut, was advanced 5 feet through porphyry and clay; total length, 222 feet. The joint Sierra Nevada and Union east drift from the station advanced 5 feet through hard porphyry; total length, 607 feet. At the Union Con. 1600-foot level, the west crosscut started at the south lateral drift, 200 feet from the joint west crosscut, has been advanced 6 feet through porphyry; total length, 103 feet.

WASHOE COUNTY.

At Olinghouse, near Wadsworth, W. Port, C. C. Howell and D. R. Wilkerson are sinking a shaft on the Gus, one of the group they have under lease and bond. J. C. Effrick and R. Nelson have a lease on the No. 1 mine, owned by Short Bros.

J. Sparks, principal owner, says sinking on the Wedekind group, near Reno, will be resumed and go down to 500 feet. The shaft is 190 feet deep.

NEW MEXICO.

BERNALILLO COUNTY.

R L. Baca of Santa Fe reports locating a group of claims in the Sandia mountains, 7 miles from Bernalillo, which show values in iron and copper ore. He has begun development work.

GRANT COUNTY.

The smelting plant of the Silver City R. Works Co., south of Silver City, was totally destroyed by fire on the 2d inst. It is supposed the fire started from a spark from an engine. The plant was valued at $100,000, with $15,000 insurance. It was owned by the Hearst estate.

In Shakespeare district a 50 H. P. steam hoist is being put in at the Dacotah Pearl mine, owned by the Michigan-New Mexico C. Co. of Lordsburg. The shaft is down 120 feet and the company proposes sinking to 500 feet and then putting in a fifty-ton leaching and cyanide plant. Work in Chloride Flat district, 2 miles from Silver City, was started last week. A. G. Witzel has leased the Baltic mine and started work, with N. Fisher as superintendent. J. R. Brent and J. A. Card have a lease on the '76 and the Bremen group. Near Pinos Altos, at the Mountain Key mine, W. C. Chandler, owner, has fifteen men at work on the 700-foot level, drifting and stoping, and some high grade ore has been blocked out. The ore is a sulphide, carrying gold, silver and copper.——The Shamrock G. & S. Co. has a lease on the Pacific mine, owned by the Hearst estate. The wagon road between the mine and the smelter has been repaired. The company has put in a sixty-ton furnace. Development work in the Silver Cells mines is going ahead.

The Santa Rita M. Co. at Santa Rita report making a steady output of 500,000 pounds of refined copper per month. They are crushing 150 tons of ore per day and the capacity of the mill will be increased.

SOCORRO COUNTY.

Manager J. M. Bryson has bought for the Dividend M. & S. Co. the copper mines at Estey. This group carries sui-

phide ores. The company will build a 500-ton concentrator and make other improvements.

OREGON.

BAKER COUNTY.

Platinum has been found in the Ruby vein of the Standard mine, near Sumpter, says E. W. Mueller, manager.

The McKinley and Roosevelt group, in Cable Cove district, near Sumpter, owned by the Advance M. Co., will begin operations this month. There is a 54-foot shaft on the ledge, with the vein showing 7 feet between the walls, with 4 feet of free milling ore running $15 per ton.

H. D. Nelson, superintendent of the Alpine mine, near Sumpter, says machinery for the stamp and saw mill is on the ground. The saw mill will be set up first to cut timber for the buildings to be erected.

President J. Thomsen, of the May Queen mine, near Sumpter, says he has doubled his working force and will both drive ahead and sink on the mine. As soon as they get down 50 feet on the ore shoot, it is intended to put in a hoist and compressor.

GRANT COUNTY.

O. C. Wright, president of the Blue Bird M. Co. at Sumpter, and E. C. Allen of Portland have bought the holdings of the Black Butte M Co., which include thirty quartz and placer claims (608 acres), 9 miles from the Dixie Butte, in Fox valley. The group has a mill on it with a daily capacity of thirty-five tons. Mr. Allen will have superintendence and a hoist with a capacity of 500 feet depth will he set up, sinking beginning on the Black Butte proper. The company will turn Belshaw creek into the placer reservoirs, which will insure an abundance of water for an entire season.

WALLOWA COUNTY.

(Special Correspondence) —The Eureka M. & S. Co., with offices at Lewiston, Idaho, and operating near Snake river, in Imnaha district, have put in operation their steamer for transportation of ore and supplies between Lewlston and the mines.

Lewiston, July 6.

SOUTH DAKOTA.

CUSTER COUNTY.

The Black Hills-Duluth C. Co. has been incorporated to operate a group near the limestone range west of Custer. The ores carry copper and gold. T. A. Towner, W. A. Nelson, F. M. Hanley and M. J. Bailey, all of Custer, are directors. A diamond drill will he used to prospect the ore bodies. The property adjoins that of the Central Black Hills C. Co.

LAWRENCE COUNTY.

It is reported the Homestake M. Co., at Lead, is preparing to increase its milling capacity by the erection of a 400-stamp mill. The company is dropping all of its 900 stamps and crushing on an average 3600 tons of ore daily. The ore is amalgamated and then submitted to cyanide treatment.

The Jupiter G. M. & M. Co. resumed full operations at its cyanide plant on Blacktail gulch, near Central City.

The Pennsylvania M. Co., on Rutabaga gulch, near Deadwood gulch, near Deadwood, are putting in additional machinery consisting of boiler, air compressor, air drills, steam hoist and pump, and will add several hundred feet to the depth of the workings.——The Big Four M. Co. is also building, across Deadwood gulch, from the works of the Pennsylvania Co. A shaft house is going up and the machinery is on the ground.

A cyanide mill will be erected on the Buxton-Big Bonanza mine, near Lead, says J. Lundberg of Clinton, Iowa, manager.

The Spearfish G. M. & R Co., operating near Spearfish, in its annual report for the year ended May 1, shows that 54,929 tons of dry ore, having an average assay value of $5.285, were treated; loss in tails, $1.20 (8%), leaving a bullion recovery of $223,970.80, or an average recovery of $4.07 (7%) per ton. The total of mining, milling and incidental costs was $143,833.47 ($2 616 per ton).

R. B. Hughes, manager of the Cleopatra Co., on Squaw creek, 10 miles west of Deadwood, says a vein 30 feet wide has been opened up on the quartzite. The ore does not carry sufficient values to pay for mining same, but it is believed that another shoot will be found by sinking. The company will put in an air compressor, air to he used instead of steam for the drills.

PENNINGTON COUNTY.

The Golden West M. Co. started its Chilian mill, 2 miles west of Rochford, last week on free-milling ore running $4 per ton from the Yellow Bird and Benedict mines.

The Ajax M. Co. is putting in machinery at the Standby mill at Rochford, and expect to start up next week. It is intended to put in cyanide vats. J. Baker of Lead is manager. The mine is opened by a shaft 200 feet deep, cut by a tunnel from the level of the mill. The mill is equipped to run by water power, and will have steam also.

UTAH.

The annual report of Assayer B. H. Tatem, in charge of the United States assay office at Helena, Mont., just issued, shows the production of metals in the State of Utah for 1902, valued at $27,882,153, being an increase over the production of 1901 of $790,443. The production of the leading metals follows: Gold, $3,972,235; silver, $16,391,804; copper, $3,015,415; lead, $4,500,618.

The month of June, in the ore and bullion market, closed on settlements aggregating $1,604,510, these figures being independent, however, of those recorded at the Independent smelters that during the same period forwarded to the Eastern refineries 2,546,686 pounds of copper carrying gold and silver, and which had a valuation of $650,000, says the Salt Lake Tribune. On this basis the output of Utah during the year will be made to exceed $25,000,000. During the first half of the year several of the furnaces have been frequently interrupted. Notwithstanding this, the total output for 1903 to July 1 exceeded $11,000,000. The mines are prepared for a greater tonnage and there is to be added to the output of the last half of the year 1903 the product of at least two smelters that are being built.

BEAVER COUNTY.

The owners of the Cave mine, near Milford, will put in a pump on the tunnel level in order that sinking may be resumed on the vein.

BOX ELDER COUNTY.

The Utah-Nevada G. & C. Co., with main offices at Ogden, has been incorporated to operate a group of five claims in Newfoundland mining district, T. Cunningham, J. Chez, D. Jensen, E. P. Stone, E. A. Stratford, J. S. Dee and D. S. Tracy are directors.

CARBON COUNTY.

A. H. Tarbet of Salt Lake City says oil-drilling operations in Dairy Fork canyon, near Price, will he continued and the well completed.

GRAND COUNTY.

The Intermountain Asphalt Co. has been incorporated at Salt Lake City to operate in the carboniferous district of Grand county; W. H. Innes, N. Forsberg, R. W. Schuttler, T. Schenck, A. G. Mahan, R. M. Pope. W. H. Innes of Boise, Idaho, is president. The company has bought 480 acres of land near the headwaters of Willow creek, where is a deposit of asphaltum which can be mined at moderate cost. A 100-ton refinery will be erected. They claim that the entire cost of mining, refining, hauling and freight to Boston, Mass., will be $17.50 a ton, where the market price is $40 a ton.

IRON COUNTY.

Development work will be increased at the Venus mine, near Stateline, and additional machinery will be put in.

The Utah Iron & Coal Co. has been incorporated in Colorado by A. B. Lewis of Salt Lake City, W. A. Clark of Montana, C. C. Parsons of Denver, Colo., et al, and they have bought an aggregate of 5000 acres of iron ore land in Iron county. They propose to spend $25,000,000 to erect a complete steel plant, with railroads and other adjuncts. Purchases of coal lands have already been made. The iron lands bought are the Campbell estate and the Cullen, Ryan, McGarry, Corry, McGurrin and the Duffy holdings, as well as those of the Utah Iron Co., et al.

JUAB COUNTY.

The Illinois M. Co. has given an option on its holdings north of Eureka and adjoining the Raymond group to F. J. Westcott for $200,000.

It is reported the Tintic M. & Dev. Co., which owns the Sioux-Ajax tunnel, near Eureka, has been absorbed by a new incorporation, the Tintic Co., which also succeeds to the Bingham properties and the proposed new smelter, says the Tintic Miner.

The shipments of ores from Tintic district during month of June amounted to 537 carloads, the principal producers being: Bullion-Beck, 21 cars; Continental-Eureka, 138; Dragon iron mine, 91; Eureka Hill, 35; Grand Central, 50; Gemini, 50; Lower Mammoth, 38; Star Con., 24; Victor Con., 12; Yankee, 26.

PARK COUNTY.

E. L. White of Boston, Mass, president of the Bingham Con. M. Co. of Bingham, Utah, and a director of the Montana Coal & Coke Co., operating at Horr, says the No. 4 mine has a vein of coal 5 feet in width. The company has 260 coke ovens in operation.

PIUTE COUNTY.

A group of claims, 12 miles south of Marysvale, on Ten-mile creek, has been sold and the Mining & Water Power Co. incorporated, with J. Patton of New York as president and R. De Witt manager. A tract of land has been bought for water-right purposes on which will be built an electric power plant.

SALT LAKE COUNTY.

The Continental M. & S. Co, H M. Crowther of Salt Lake City managing director, has bought the Regulator, Grizzly, Lavina and Darlington mines at Alta, and will begin development this week. They contain ore bodies averaging $25 a ton in values. In the Lavina tunnel is a vein 30 feet wide, sampling 15 ounces of silver, 0.8% copper, 10% lead and $1 gold; in the Upper Grizzly tunnel a 40-foot vein averaging 4% copper, 9 ounces of silver and $1 in gold; on the 100-foot level of the Lavina an 18-inch vein averaging 16% lead, 80 ounces of silver and .04 ounce gold.

SUMMIT COUNTY.

The Park Record says in Park City district ten shafts have reached a depth of at least 1000 feet, six are down over 1800 feet, and one is 2000 feet deep. There are four drain tunnels, the longest one being the Ontario lower tunnel, which is 3 miles in length.

A compressor has been put in at the Naildriver mine, near Park City. The shaft is down 250 feet.

TOOELE COUNTY.

The Senate M. Co. of Salt Lake City has been incorporated by J. B. Black, C. Reich and W. M. Bradley. The company owns the Dolphin group and has an option on the Index, in the Erickson and Columbia districts.

WASHINGTON.

FERRY COUNTY.

It is reported work will be resumed next week on the California mine, near Republic, which is temporarily closed down. New plans for development are under consideration.

A survey is being made for a ditch from Bridge creek to the Gold Cord smelter site at Keller, where power will be developed for running the smelter machinery, an electric light plant and a sawmill.

Men are at work on the Oversight group, near Republic, and the tunnel is expected to cut the ledge by Aug. 1 at a depth of 150 feet. The work is ½ mile south of the Belcher lead. The mine is owned by Seattle men.

The Waneta G. M. Co. will sink a shaft on the Oregonian claim, one of their group, adjoining the Morning Glory on the north.

SNOHOMISH COUNTY.

It is reported negotiations are under way for the sale of the Everett smelter, owned by J. D. Rockefeller, to a company headed by C. Sweeney of Spokane. The smelter was built by Rockefeller to handle the ores of the Monte Cristo mines.

STEVENS COUNTY.

The I. X. L. group of iron properties in Clugston district, 12 miles east of Bossburg, will be reopened. The group is owned by F. B. Geotter of Colville. The ore is brown oxide of iron (limonite), which is said to average 46% iron, 40% silica, 2% alumina, .3% sulphur and .31% phosphorus. There is also some hematite. The development work consists of two tunnels, a winze and open cuts.

At the Walter Scott mine, near Northport, developments are progressing and additional machinery will he put in. The tunnel will be continued. G. E. Needy of Spokane is president.

WEST VIRGINIA.

PLEASANT COUNTY.

F. R. Anson of New York has bought the holdings of the Octo Oil Co. of Pittsburg, Pa., for $350,000, being a large area of shallow sand territory in St. Mary's district, and the Wolf Creek and Chester Hill districts in Washington and Morgan counties, Ohio. Anson secures the lease on 1500 acres of territory in which are seventy-seven producing wells, having a net aggregate production of 350 barrels a day.

FOREIGN.

AFRICA.

CONGO FREE STATE.

On the Tanganyika concessions Resident Engineer Buttgenbach at Lukonzolwa reports drive at Likasye mine contains 52 kilograms of silver per metric ton. The drive on the Likasye mine is being extended in the copper ore at depth of 100 feet.

TRANSVAAL.

The Middleburg Steam Coal & Coke Co., near Johannesburg, has commenced production.

The Van Ryn Gold Co., operating near Johannesburg, have fifty stamps dropping.

AUSTRALIA.

NEW SOUTH WALES.

In Bathurst district between twenty and thirty claims have been taken up at the junction of St. Anthony's creek with Winburndale creek on the Glanmire estate, 10 miles from Bathurst, near the site of the former Glanmire gold field. The working is alluvial, and wash dirt averages 6 feet and sinking from 16 to 60 feet. The Prospectors' claim runs 8 feet of wash and averages from 3 to 7 dwts. of gold to the load. At the junction of Cheshire's creek with Winburndale, near Dumara, numbers of men are working alluvial ground in shallow sinking.

Driving from the bottom of shaft 270 feet deep in search of alluvial lead, the Newstead M. Co. at Invereil cut a lode 6 feet wide, rich in tin ore. The manager states the lode appears to be nearly vertical, hearing northeast and is in granite.

QUEENSLAND.

The Bonnie Dundee Gold Co., at Charters Towers, report No 2 shaft down 1900 feet, work having resumed June 19th.

VICTORIA.

The value of the gold won during the half year ending June 1 at the Madame Berry West mine at Creswick was £16 340.

The New Dampsey G. M. Co. at Gaffneys during the past half year won gold of value of £15,289, and expended £2897 in getting it. In the northwest stopes the reef is 50 feet high; to the southwest it is smaller, but of better quality. The stone crushed totalled 1140 tons, which yielded 3866 ounces, while the nineteen tons of sand yielded 163 ounces additional.

WEST AUSTRALIA.

Lake View Consols mines near Kalgoorlie report May returns 7541 tons of ore treated, yielding 4840 ounces fine gold. Costs for the month: Stoping, 10s 10d. per ton; ore reduction, ("Diehl" treatment), 16s. 10d. per ton; general expenses, 3s. 3d.; total working expenses, 30s. 11d; total for month, £11,657. Expenditure on machinery and plant, £596; expenditure on mine development, £3685.

BRITISH COLUMBIA.

(Special Correspondence) — In Slocan mining division the American Boy mine at Sandon is shipping three cars of ore per week. More men have been taken on at the mine, but the tunnels are still too wet to allow the force to be increased as intended by Manager McGuigan. The Slocan Star has resumed shipments after a short cessation due to the bad condition of the wagon road. Machine drills have been put in. A new ore house is being built at Red Fox mine, near McGuigan. A ledge has been uncovered on the Erin, near Slocan City, 8 feet wide and extending into the Republic ground. The ore carries copper, with 100 ounces of silver per ton.

In Lardeau mining division a strike on the Guinea Gold mine shows the ore body which has been developed in the upper workings at a vertical depth of 200 feet. The ore will net $103 per ton in all values. The Horse Shoe mine at Trout Lake has been sold to Philadelphia, Pa., parties, says G. W. Stead, manager of the Ethel and Lucky Boy mines, for $16,000. A strike of 4 feet of shipping ore was made on the Lucky Boy last week, showing gray copper and carbonates, with silver values. The Oyster-Criterion dam is finished and the flume is being built. Grading for the compressor plant and stamp mill is under way. At the Eva a contract has been let for clearing the tram line and work on the dam was started last week. Grading of stamp mill site is completed.

Nelson, July 5.

When the coal miners at Ladysmith and Cumberland requested Dunsmuir to allow them to return to work last week they were asked to sign a contract, which they refused to do Dunsmuir says that unless the Ladysmith strikers accept his proposal and go back to work the Extension collieries will he reopened and worked by Asiatics and non-union men. The latest reports say that the Cumberland miners are still out and intend staying out. The mines, however, since the inception of the trouble have been worked by Asiatics exclusively, 1000 men being used. The Government intends to enforce the law passed at the last session of Parliament, which excludes the Chinese from the collieries, and accordingly the inspector of mines will leave for Cumberland next week to investigate and put them out.

Two hundred and twenty-four Nanaimo miners working on the Long Wall mine, operated by the Western Fuel Co. of San Francisco, Cal, laid down their tools and walked out on the 6th inst, because the company withdrew the extra wage allowance.

It is expected that the Lenora mine at Mount Sicker will resume work this month under control of Bellinger & Breen of the Northwest Smelting Co. The firm

takes over not only the mine, but the entire business connected with it, including machinery, the railway to Crofton, the rolling stock and the hotel. W. T. Tregear is manager.

The Crow's Nest Pass Coal Co., operating at Fernie, Morissey and Michel, report their June output at 75,000 tons. The Coal Creek mines are increasing their output.

At Erie, near Ymir, besides Finch & Campbell's Second Relief, where thirty-five men are working in the mine and mill, the Canadian King mine is being operated under lease by W. Connelly and B. Porter.

At the Arlington mine forty men are at work.

W. S. Keith has a lease and bond on the Ruby claim at Boundary Falls.

The zinc plant being built at the Payne mine at Sandon, in the Slocan, is expected to be ready for operation next week.

Superintendent W. Myers has resumed work at the Watson mine near Fort Steele. This is a silver-lead group on Victoria gulch, a tributary of Wild Horse creek.

It is reported operations are to be resumed on the Tiger-Poorman group of mines, on the divide between the North Fork of Wild Horse and Sheep creek near Fort Steele.

Shipments from Rossland camp for the week ending July 4 and for the year to date are as follows, says the Rossland Miner:

	Week. Tons.	Year. Tons.
Le Roi	1,920	92,345
Center Star	1,290	42,208
War Eagle	1,290	29,775
Kootenay	465	2,870
Le Roi No. 2	450	14,142
Velvet	50	3,076
Giant	120	575
I. X. L.	....	40
White Bear	....	297
O. K.	....	25
Homestake	....	90
Totals	5,585	185,422

CONCENTRATES SHIPPED.

War Eagle-Center Star	90	90

Total year's shipments to date.185,512

This makes a total of 36,360 tons for the month of June. It is expected the Le Roi will increase its output this month. The obtaining of an adequate coke supply at the Le Roi smelter in Northport, Wash., will bring a further increase in output. In addition, several new mines will be on the shipping list before the end of the year. The past week shipments were begun from the Jumbo mine, operations resumed at the Gold Hill group and the mechanical plant at the Spitzee mine finished and underground operations begun; also, the first shipment of concentrates from the War Eagle-Center Star concentrator was made.

Shipments from the Boundary district for the same period were:

	Week. Tons.	Year. Tons.
Granby	4,927	162,535
Mother Lode	2,697	49,735
Snowshoe	1,920	25,830
B. C.	1,020	16,435
Emma	210	9,416
Sunset	512	5,949
Providence	....	591
Athelstan	60	60
Totals	11,346	270,680

The Granby smelter treated 4205 tons for the week, making a total of 154,661 tons for the year.

COLOMBIA.

The Darien Gold M. Co. reports for May show: Crushed, 2272 tons and obtained 4295 ounces gold, value $84,500. Sinking continues in the Maisounabe shaft and in the Lodin shaft.

KLONDIKE.

J. J. Rutledge, operating placers near Dawson, will put in a dredger on Forty-Mile river to cost $140,000. Rutledge says if this dredger proves successful it will be followed by twenty more dredgers, which he will have in operation on Forty-Mile river within 5 years. It will handle 3000 cubic feet of gravel daily.

MEXICO.

COAHUILA.

A number of the coal mines around San Felipe and Hondo were flooded by the heavy rains last week, says the Enterprise. Most of the flooded mines are owned by the International Railroad.

CHIHUAHUA.

The San Francisco, Cal., men owning the McDermott - O'Callahan group at Santa Eulalia have started work. Diamond drilling machinery will be put in. G. B. Jacobs is general manager.

DURANGO.

The San Acacio M. Co., owning the San Acacio mines at San Juan de Guadalupe, is building a railroad to connect with the Mexican Central.

A. T. Grove, secretary of the American-Mexico M. & D. Co., operating at Velardena, says they are putting in additional machinery.

The Pittsburg Gold Co., operating tin mines at Jaltomates, report opening another vein of tin ore.

M. & R. de la Parra have obtained a concession to exploit a large sulphur deposit known as La Tenebrosa, in Sierrita section, near Mapimi, says the Chihuahua Enterprise.

HIDALGO.

The Santa Irene y Anexas M. Co. has denounced fourteen mining claims on veins carrying gold and silver at Arenal, district of Actopan.

J. Perez and M. Garcia will work the Sacavon de la Purisima mine at the Cerro Huexotitla, municipality of Mineral del Monte.

JALISCO.

Carral & Kratz are putting up a 20-ton plant at their mine, near Etzatlan, and it is expected to be running by September 15.

Ashestos has been found in the Real mountains. It is said to be of good commercial quality.

MEXICO.

It is reported that the Esperanza mine, in El Oro camp, has been bought jointly by the Guggenheim Exploration Co. of New York and the Venture Corporation of London, England, through J. H. Hammond, manager for the former, and E. A. Wiltse, manager for the Venture. The property is well equipped and operates a 120-stamp mill.

J. Henderson, president and manager of El Porvenir de Sonora M. Co., operating a gold mine near Poza, says he expects to have the mill, which was recently damaged by fire, repaired and running next week.

OAXACA.

La Compania Petrolifera del Pacifico, S. A., has been organized to bore for oil on the Pacific coast of Mexico. E. C. Creel, F. Pimentel y Fagoaga, J. Pimentel, P. Macedo, M. S. Macedo, R. Alcazar, P. Escandon y Barron, A. Escandon y Arango, J. D. Cassasus own an area of 12,000 hectares near Puerto Angel, jurisdiction of Pochutla. A drilling outfit will be taken in.

SAN LUIS POTOSI.

A coal field is reported found near Huesteca Polosina. Several beds of asphalt are also reported in the same section.

SONORA.

At La Bufa the pump and pipe line of the Bufa M. Co. are in operation. They convey water a distance of 4½ miles and raise it 900 feet. Work on the mill buildings, matte furnace and other machinery is progressing, says the Oasis. The air compressors and machine drills will be in operation next week.

It is reported the Gutierrez M. Co., which is developing the Gutierrez mine at La Barranca, has bonded the Nahulia group of mines, at San Javier, for $65,000 gold, and the Belene mine, at La Barranca, for $75,000.

Work is under way by the Vega M. Co. on the Gabilan mine at Gabilan, says C. H. Buffett, superintendent.

W. B. Jenkins, D. N. Clemens and J. A. Cummings of Colorado Springs, Colo., have a bond and lease on a group of claims, including the Tucabe mine, 65 miles from Magdalena.

ZACATECAS.

A 100-ton milling plant has been built at the Proano mines at Fresnillo, owned by F. Ortega.

Obituary.

T. BEYNON, a pioneer mining man of Tuolumne county, died in Jeffersonville, near Columbia, Cal., June 26, after a long illness. Deceased was a native of Wales.

H. M. DRISCOLL, a pioneer mining man of Lander county, Nev., died at Galena, Nev., June 20. Deceased was a native of Ireland, aged 73 years, and is survived by two sons and two daughters.

M. MACNAMARA, a pioneer miner of Esmeralda and Nye counties, Nev., died at Silver Peak, Nev., June 27th, of miners' consumption. Deceased owned several mines in these districts, and recently sold the MacNamara group at Tonopah. He was a native of Ireland, aged 65 years.

A. H. FOWLER, a pioneer mining and smelting man of Colorado, died on the 2nd inst. at Hyannisport, Mass., after a lingering illness. Deceased was born in Connecticut and was 52 years of age. He went to Colorado in 1877, settling first at Leadville, where he was manager of the Berdell & Wetherill smelter. Later on, he was connected with the Smuggler-Union mines at Telluride, Colo., and with the Viola mine at Camas, Idaho. He is survived by a widow and three children.

PERSONAL.

L. B. RAPP of Cincinnati, O., is at Chihuahua, Mex.

A. S WISE is manager of the Black Swan M. Co., near Sunshine, Colo.

W. M. STRONG is superintendent of the Banker mine, near Leadville, Colo.

P. L. FLANIGAN, interested in mines near Reno, Nev., is in San Francisco, Cal.

W. H. WILEY, mining engineer of Idaho Springs, Colo., is in Los Angeles, Cal.

J. NEVILL is superintendent of the Treadwell group of mines near Kingman, Ariz.

A. B. DEALTRY of London, England, a director of the Le Roi Two Co., is at Rossland, B. C.

G. R. HANCOCK is vice-president and manager of the Comstock M. Co., at Park City, Utah.

J. A. SHINN of Denver, Colo., is examining mining property in Montana for Wisconsin parties.

G. L. KEENER has resigned as manager of the Mary McKinney mine at Anaconda, Teller county, Colo.

W. W. WHITE is superintendent of the Bonnie mine, near Prescott, Ariz., vice J. J. Brooks, resigned.

MANAGER G. H. DERN of the Con. Mercur M. Co. at Mercur, Utah, is in Jersey City, N. J., on business.

R. C. VIDLER of Georgetown, Colo., is visiting New York and other Eastern cities on mining business.

J. PRICE has resigned as superintendent of the Mary McKinney mine at Anaconda, near Cripple Creek, Colo.

C. SCHIERMEISTER, a mining engineer of Berlin, Germany, is traveling through the mining camps of Mexico.

W. E LLOYD is manager of the Sioux Falls & Cripple Creek M. & D. Co., operating near Cripple Creek, Colo.

G. E. MCCLELLAND, manager of the Monarch tunnel, Idaho Springs, Colo., is in the East on mining business.

A. H. ELFTMAN of Minneapolis, Minn., manager of the Miller mine, Brownsville, Cal., is inspecting the property.

L. S. WOOD has returned to Denver, Colo., from Empire, Colo., where he has been examining mining properties.

G. LAND is superintendent of the Keystone Hydraulic M. Co., operating near Telluride, San Miguel county, Colo.

F. A. KEITH is superintendent Bamberger's De Lamar mines and mill at De Lamar, Nev., vice F. Janney, resigned.

G. KARTSCHOKE has resigned as superintendent of the Delhi mine of the St. Gothard M. Co., near Nevada City, Cal.

W. T. TREGEAR, former manager Le Roi mine at Rossland, B. C., is manager of the Lenora mine at Mount Sicker, B. C.

W. H. BATES, manager of the Oro Concentrating Co., is in San Francisco, Cal., from Prescott, Ariz., on mining business.

S. K. THORNTON, superintendent of the Shenandoah mine, near Plymouth, Cal., is in San Francisco, Cal., on mining business.

F. ESCHER has resigned as manager of the Americana mine at Terrazas, Chihuahua, Mex., and will take a trip to Europe.

A. K. COOMARASWAMY, F. G. S., has been appointed director and J. Parsons as assistant of the Mineral Survey of Ceylon.

N. WILLIAMS is superintendent of the Olsen mine, at Don Pedros Bar, 5 miles south of Chinese Camp, Tuolumne county, Cal.

WILLIAM VARDI of Nady-Halmagy, Hungary, a mining engineer for the Hungarian Government, is at Cripple Creek, Colo.

W. W. BYRNE, treasurer of the Polar Star M. Co., is at their mines, near Nevada City, Cal., from Salt Lake City, Utah.

W. SWANSON is superintendent of the Abe Lincoln mine, near Cripple Creek, Colo., being operated by the Tunnel M. & L. Co.

P. M. MCKINNEY is superintendent of the Santa Emilia and Dona Louisa mines, Michoacan, Mex., vice J. C. Collinson, resigned.

W. C. GREENE of New York, president of the Greene Con. C. Co., is visiting their mines and smelters at Cananea, Sonora, Mexico.

A. T. GROVE, secretary and treasurer of the American-Mexico M. & Dev. Co., is at the company's mines at Velardena, Mexico.

M. HIRSCH of New York, with S. Bamberger and J. D. Wood of Salt Lake City, Utah, are in Los Angeles, Cal., on mining business.

J. W. TAYLOR, manager of the Tuna Co.'s mines in Lemhi county, Idaho, returned to Salt Lake City, Utah, from a trip East.

C. L. DIGNOWITTY of Salt Lake City, Utah, is at Boulder, Colo., on mining business, from which place he will go to Deadwood, S. D.

M. E. PINNEY, superintendent of the Nigger Hill mines, near Jamestown, Cal., is in San Francisco, Cal., on business for his company.

E. J. BONSTELL, who recently returned to San Francisco, Cal., from Groveland, Cal., has gone to Sutter Creek, Cal., on mining business.

LINDSAY CLARK is manager of the Brisels Tin M. Co. mines, near Hobart, Tasmania, whose branch office is at Melbourne, Victoria.

T. F. MCGOVERN has resigned as superintendent of the Republican mine, near Jacksonville, Cal., to devote his time to his other interests.

DR. A. E. SAYOUS of Paris, France, is in California on a French Government mission relative to a study of mining conditions in that State.

W. J. DOOLY, manager of the Johnny mine of Stateline, Utah, returned to Salt Lake City, Utah, last week from a trip to Nevada and California.

MANAGER C. W. WHITLEY of the American S. & R. Co. returned to Salt Lake City, Utah, last week after an extended visit in the East.

HAVEN SAWYER, superintendent of the Dewey mine, Siskiyou county, Cal., is in San Francisco, Cal., returning from a business trip to Boston, Mass.

A. P. GRIFFITHS, A. R. S. M., late general manager of the Palmarejo & Mexican Goldfields, Ltd., has returned to London, England, from Mexico.

M. L. REQUA, president of the Pacific Steel & Wire Co. of San Francisco, Cal., has gone to Eureka, Nev., near which place he has large mining interests.

JUNSUKE JIGIMA of Tokio, Japan, manager of the Ahoe copper mines, is examining copper smelting methods in the principal Utah and Montana camps.

S. BAMBERGER AND J. D. WOOD of Salt Lake City, Utah, and M. Hirsch of New York, are in Los Angeles, Cal., from Salt Lake City on mining business.

J. P. EMPSON, formerly with the Dakota M. Co., is to be cyanide superintendent of the Reliance G. M. Co.'s plant, which will be built near Deadwood, S. D.

J. A. GROESBECK of Salt Lake City, Utah, has gone to Cerro de Pasco, Peru, as superintendent of a group of placer properties owned by the Cerro de Pasco M. Co.

W. C. THOMAS, former superintendent of the Highland Boy smelter at Bingham, Utah, is superintendent of the smelter of the Newhouse M. & S. Co., near Salt Lake City, Utah.

F. JANNEY has resigned as superintendent of Bamberger's De Lamar mines and mill at De Lamar, Nev., and accepted a similar position with the Utah C. Co. of Bingham, Utah.

C. F. V. JACKSON, an assistant geologist on the Queensland Geological Survey staff, has resigned, having been appointed first assistant geologist on the West Australian staff.

J. EDDIE, formerly superintendent of the Gold Tunnel mine, is superintendent of the Delhi mine of the St. Gothard M. Co., near Nevada City, Cal., vice G. Kartschoke, resigned.

T. HOOPER of Rockland, Lake Superior, Mich., has returned there from a trip through Sonora, Mexico. He also stopped at Idaho Springs, Colo., to examine mining property.

L. A. WOMBLE, M. E., of Berkeley, Cal., who has been connected with the Bunker Hill & Sullivan mines at Wardner, Idaho, leaves shortly to accept a position in South Africa.

Books Received.

"Earth Work and Its Cost" is the title of a neat volume of 244 pages, hy Halbert P. Gillette. It deals with tbe art of cost estimating; tbe handling of earth hy means of various devices; transporting the loosened earth hy means of wheelbarrows, carts, dump carts, scrapers, wagons, steam shovels, etc. It also goes into excavating by dredging, bydraulicking and by other means. The book Is illustrated and will prove of use to tbose engaged in tbe work of excavating on a small or large scale. $1.50; The Engineering News Publishing Co., New York City.

"Electrical Engineering," by E. Rosenberg, translated hy W. W. H. Dee and C. Kinzbrunner, is a new treatise on electricity designed as an elementary text book suitable for those employed in electrical and engineering pursuits. Besides tbe fundamental phenomena of the electric current, dynamos and motors for continuous, alternating and three-phase current, accumulators, measuring instruments and electric lighting are treated. Those desiring a knowledge of electricity, but who have no immediate connection with the profession, will he instructed in mucb useful and necessary knowledge by reading this volume. It is profusely illustrated; 8vo. XIII+267 pages. Cloth, net, $1 50; Jobn Wiley & Sons, 43 East Nineteenth street, New York City.

Catalogues Received.

"Colors and Specifications" is tbe title of a folder from tbe Joseph Dixon Crucible Co. of Jersey City, N. J., graphically illustrating paint specifications for steel and iron construction and maintenance work. James G. Allen, 304 Market street, San Francisco, Cal., is their Pacific coast agent.

Commercial Paragraphs.

A. LESCHEN & SONS' ROPE CO., St. Louis, Mo., manufacturers of wire rope and aerial wire rope tramways, have moved tbeir San Francisco, Cal., office to the Rialto building, corner New Montgomery and Mission streets. Tbeir other offices remain as heretofore, namely: 920–922 North First street, St. Louis, Mo.; 137 East Lake street, Chicago, Ill.; 92 Center street, New York, N. Y.; 1717–1723 Arapahoe street, Denver, Colo.

New Patents.

DEWEY, STRONG & CO.'S SCIENTIFIC PRESS PATENT AGENCY, 330 Market St., S. F., has official reports of the following U. S. patents issued to Pacific ccast inventors:

FOR THE WEEK ENDING JUNE 30, 1903.

732,508.—TUBE SHEET PROTECTOR—C. H. Boone, San Leandro, Cal.
732,263.—METALLURGICAL FURNACE—M. P. Boss, S. F.
732,264.—METALLURGICAL FURNACE—M. P. Boss, S. F.
732,265.—METALLURGICAL FURNACE—M. P. Boss, S. F.
732,266.—METALLURGICAL FURNACE—M. P. Boss, S. F.
732,267.—METALLURGICAL FURNACE—M. P. Boss, S. F.
732,268.—METALLURGICAL FURNACE—M. P. Boss, S. F.
732,269.—METALLURGICAL FURNACE—M. P. Boss, S. F.
732,510.—VEHICLE FRAME—G. R. Boulding, Wells, Nev.
732,172.—EXCAVATOR—W. Cole, Olympia, Wash.
732,173.—EXCAVATOR—W. Cole, Olympia, Wash.
732,278.—TIRE PROTECTOR—L. C. Cummings, Pasadena, Cal.
732,537.—PAPER CUTTER—C. J. I. Devlin, S. F.
732,626.—PLOW AND CULTIVATOR—W. H. Fox, Gilroy, Cal.
732,538.—DREDGER—W. H Fulcher, Oakland, Cal.
732,298.—WINDOW SASH—E. Hipolito, Los Angeles, Cal.
732,563.—DESSICATING FRUIT—W. S. Keyes, S. F.
732,304.—PIANO—F. W. Kringel, Los Angeles, Cal.
732,567.—GOVERNOR—G. F Lasher, Portland, Or.
732,305.—CUFF HOLDER—C. H. Leach, Orchards, Wash.
732,580.—INDICATOR—T. J. McGrath, Portland, Or.
732,581.—INDICATOR—T J. McGrath, Portland, Or.
732,649.—SAWMILL—H. S. Mitchell, Seattle, Wash.
732,653.—RAIL BRACE—D. D. Quenell, Riparia, Wash.
732,319.—CONCENTRATOR—Rogers & Hanson, S. F.
732,655.—JAR CLOSURE—J. H. Saunders, Olympia, Wash.
732,452.—BASIN PLUG—W. F. Schultheiss, San Diego, Cal.
732,592.—BOTTLE—H. V. Scott, S. F.
732,605.—LEACHING ORES—G. E Thede, Havilah, Cal.
732,650.—RACING HURDLE—R. P Traxler, S. F.
732,667.—BEEHIVE—H Vogeler, Newcastle, Cal.
732,477.—ELECTRIC SWITCH—I. G. Waterman, Santa Barbara, Cal.
732,608.—ELECTRIC FLOAT—I. G. Waterman, Santa Barbara, Cal.
732,148.—SAWMILL—A. J. West, Aberdeen, Wash.

Our Eastern Business Manager.

On the 1st inst. Mr. Wm. Starr Bullock assumed charge of the business interests of this journal as special Eastern representative, with offices at 720 Park Row Building, New York City. Mr. Bullock's business acquaintance and personality commend him favorahly to present and prospective patrons.

Notice of Recent Patents.

Among the patents recently obtained through Dewey, Strong & Co.'s SCIENTIFIC PRESS U. S. and Foreign Patent Agency, the following are worthy of special mention:

EXTRACTING GOLD OR SILVER FROM SLIMES.—No. 731,631. June 23, 1903. J. T. Perry, Jr., Altar, Mexico. One-half assigned to J. O. Treanor of same place. This invention is designed to extract precious metals from the slimes or other unleached material hy the aid of cyanide solutions. It consists in spraying the slimes or slime mixed with water and called "sludge" into tanks which are partly filled with the cyanide solution containing oxidizing agents, such as calcium hypochlorite, or other active chemical agents, such as hromo-cyanide, and without agitation allowing the same to settle, drawing off the clear solution, then discharging the sludge into similar tanks filled with solution or water, allowing the mass to settle, then drawing off the clear liquid as before.

PRINTING PRESS.—No. 12,124 (reissue). June 23, 1903. J. F. Ames, Portland, Or. This invention is especially designed for the purpose of securing printing types or characters upon a revolving cylinder so that they may he employed for printing hags, the wooden sides or parts of which boxes are constructed, and for like purposes. It consists in a novel construction of the cylinder and means for securing the type or characters thereon from which the impression is to he made, means in connection therewith hy which the type or printing surface is protected from undue pressure from the surface on which the printing takes place, means hy which the ink is prevented from being transferred to the protecting strips, and means wh rehy all the devices are securely locked to the cylinder hy a single operation.

Latest Market Reports.

SAN FRANCISCO, July 10, 1903.

METALS.

SILVER.—Per oz., Troy: London, 24⅜d (standard ounce, 925 fine); New York, bar silver, 52½c, refined (1000 fine); San Francisco, 52½c; Mexican dollars, 41c San Francisco, 41c New York.

COPPER.—New York: Standard, $14.25; Lake, 1 to 3 casks, $14.00@14 25; Electrolytic, 1 to 3 casks. $14.00@14 25; Casting, 1 to 3 casks, $13 50; San Francisco: $14.00. Mill copper plates, $17.00; bars, 18@24c. London: £57 5s spot per ton.

There has been a noticeable drop in copper the past ten days and tbe market is not all that sellers could wish. It is reported that copper has been sold for less than the quoted price. The large consumers are holding back, evidently waiting for a still lower price before making contracts for the ensuing year. It is not likely that Lake will go helow 14 cents for tbe present. Tbe price of tbe past few months—15 cents and thereabouts—has stimulated the output in no small degree, and tbe influence of tbis increased output is now being felt. In tbe latter part of June, Calumet & Hecla offered copper in New York at 14½ cents and tbus broke the price that had prevailed. A reduction of one-half cent per pound seems small, hut it means a large sum to heavy producers. The following tahle shows tbe montbly exports of copper for the first five months of tbe year, in pounds:

	1903.	1902.
May	23 254,334	35,498,848
April	26,321,400	34 372,011
March	31,515,468	38,679 965
February	21,813,242	32 814,949
January	24,552,687	32,085,041
Total pounds.	127,451,131	173,450,814

It is thougbt hy some tbat the enforced shut-down of tbe Anaconda Company for several months pending the completion of improvements in tbeir reduction works may have a direct effect on the market.

LEAD.—New York, $4.12½; Salt Lake City, $3.50; St. Louis, $4.00; San Francisco $4.50, carload lots; 4¾c 1000 to 4000 lbs.; plpe 5½, sheet 6, bar 5½c; plg, $4.75. London: £11 6s 3d per long ton=2.75c per lb.

SPELTER.—New York, $5.87½; St. Louis, $4.85; London, £20 17s 6d per ton; San Francisco, ton lots, 6½c; 100-lb lots, 7c.

ANTIMONY.—New York, Cookson's, 9¾c; Hallett's, 8½c; San Francisco, 1000-lb. lots, 10c; 300 to 500 lbs., 11c; 100-lb. lots, 13@15c.

TIN.—New York, plg, $27.15@27.40; San Francisco, ton lots, 29½c; 500 lbs., 30c; 200 lbs., 30½c; less, 31c; bar tln, ℔ lb, 32½c @35c. London, £123 17s 6d spot.

PLATINUM.—San Francisco, crude $18.00 ℔ oz.; New York, ingot, $19.00 per Troy oz. Platinum ware, 75@80c per gram.

QUICKSILVER.—New York, $44.50@46.00; large lots; London, £8 15s; San Francisco, local, $44.50 ℔ flask of 76½ lbs.; Denver, $49.50. Export, $43.50.

BABBITT METAL.—San Francisco No. 1, 10c; No. 2, 7c; No. 3, 6½c; extra, 17½c; genuine, 35c; Eclipse, 37½c.

ALUMINUM.—New York, No. 1, 99% pure lngots, 35c; No. 2, 90%, 30c to 34c.

SOLDER.—Half-and-half, 100-lb. lots, 19½c; San Francisco, Plumbers', 100-lb. lots, 16c.

NICKEL.—New York, 50@60c ℔ lb.; ton lots, 45@48c.

STRUCTURAL MATERIALS.

IRON.—Pittsburg, Bessemer plg, $19.50 @19.85; gray forge, $18 60; San Francisco, har, 3c ℔ lb., 3½c in small quantities.

STEEL.—Bessemer hillets, Pittsburg, $29 50@30.50; open hearth billets, $31.50; San Francisco, bar, 7c to 12c per lb.

No. 2** 30% carload lots, 9c; less than one ton, 11c. Black blasting powder in carload lots, minimum car 728 kegs, $1.50 per keg; less car lots, $2 per keg.

CAPS.—3x, $5.50 per 1000; 4x, $6.50; 5x, $8; Lion, $9, in lots not less than 1000.

FUSE.—Triple tape, $3.60 per 1000 feet; double tape, $3.00; single tape, $2.65; Hemp, $2.10; Cement No. 2, $3.00; Cement No. 1, $2.65, in lots of 3000 feet and up.

CANDLES.—Granite 6s, 16 oz., 40s., 10½c ℔ set; 14 oz., 40s., 9½c.

CHEMICALS.—Cyanide of potassium, 98%–99%, johbing, 24@25c ℔ lb.; carloads, 23@24½c; in tins, 35c; soda ash, $2.00 ℔ 100 lbs.; hyposulphite of soda, 2½@2¾c ℔ lb.; caustic soda, in drums, 3@3½c ℔ lb; Cal. s. soda, hbls., $1.25@1.50 ℔ 100 lbs.; sks., $1.05; chlorate of potash, 12@13c; nitrate of potash, bbls., 10c; caustic potash. 10c ln 40-lb tins; horax concentrated, 7@8c ℔ lb.; roll sulphur, 4@6c; powdered sulphur, 2@ 3c; flour sulphur, French, 2@3c; alum, $2.00@2.25; Californla refined, 2@2½c; sulphide of iron, 9c ℔ lb; copper sulphate, 5@7c; chloride of lime, spot, $2 50@2.75; sulphuric acid, in carboys, 66% B, 2½c ℔ lb.; nitric acid, in carboys, 8c ℔ lh.

OILS.—Linseed, hoiled, bbl., 51c; cs., 56c; raw, bbl., 49c; cs., 54c; Lucol oil, boiled, bhl., 48c; cs, 53c; raw, bbl., 46c; cs, 51c. Kerosene—Pearl, per gal., 20½c; Astral, 20½c; Star, 20½c; Extra Star, 24½c; Eocene, 23½c; Elalne, 26½c; Water White, in hulk, 14½c; Mineral Seal, iron bbls., 18½c; wooden bbls., 21c; cs, 24c; Mineral Sperm, cs, 26½c; Deodorized Stove Gasoline, bulk, 17c; do., cs., 23½c; 86° Gasoline, bulk, 21c; do., cs., 27½c; 63° Naphtha or Benzine, deodorized, ln bulk, per gal., 16c; do., ln cs., 22½ c; Lard Oil, E. W. S., hbl., $1.00; cs., $1.05; Neats-foot Oil, pure, bbl., 75c; cs., 80c; Sperm, crude, 70@60c; Natural Whlte, 65c; Bleached do, 50c; Whale Oil, cs, 50@55c.

WHITE LEAD.—Per lb., ln kegs: 500 lbs. and over at one purchase, per lb., 6c; less than 500 lbs., per lb., 6½c; ln 25-lb. tln pails, ½c per lb. above keg price; ln 1 and 5 lb. tin cans, 100 lbs. per case, ½c per lb. ahove keg price. Dry Lead—In bbls., 1 ton and over, 6c; do. in kegs, 6½c.

RED LEAD.—500 lbs. and over at one purchase, per lb., 6c; less than 500 lbs., 6½c.

LITHARGE.—Pure, in 25-lb. bags, 8 @9c per lb.

BONE ASH.—Extra No. 1, 5@6c per lb. No. 1, 4@5c.

BORAX.—Concentrated, 7@9c per lb powdered, 9@12c; fused, 25@30c.

BORAX.—Crystal, 7c; calcined, 25c.

MANGANESE.—Pure, ℔ lb., 60c.

MOLYBDENUM.—$2 per lb.

CHROMIUM.—(90% and over) per lb., $1.00.

BISMUTH.—Subnitrate, per lb., $1.60.

SODIUM.—Metal, ℔ lb., $1.00.

MERCURY.—Bichloride, ℔ lb., 90c.

PHOSPHORUS.—(American) ℔ lb., 75c.

SILVER.—Chlorlde, ℔ oz., 90c@$1.00; nitrate, 55c.

ALUMINUM.—No. 1, 99%, small lots, 37c ℔ lb.; 100 lbs., 35c; 1000 lbs., 34c; ton lots and over, 33c, Pittsburg. No. 2, 90%, small lots, 34c; ton lots and over, 31c, Pittsburg.

URANIUM.—Oxide, ℔ lb., $3.50.

ZINC.—Metallic, chemlcally pure, ℔ lb., 50c; dust, ℔ lb., 10c; sulphate, ℔ lb., .04c.

COAL.—San Francisco, coast, yard prices: Wellington, $8.00; Seattle, $6.50; Coos Bay, $5.50; Southfield, $8.00. Cargo lots, Eastern and forelgn: Walisend, $6.50 Brymbo, $7.50; Pennsylvania, hd., $14. 00 Scotch, $8; Cumberland, $12; Cannel, $9.00; Welsh Anthracite, $11.50; Rock Springs, $9.50, long ton; Colorado Anthracite, $14.00. Coke, $10.50 per ton in bulk, $13 in sacks; Sunnyslde, $8.50, long ton.

(These prices are wholesale, f. o. b. San Francisco, unless otherwise noted.)

SITUATIONS WANTED.

A YOUNG MAN WITH 12 YEARS' PRACTICAL mining experience wants position where the ahility to do things and doing them will lead to advancement. Can assay, survey, run engine or pumps, sharpen tools, or do anything about a mine. Have some mill experience. Referenoes given. Address R. J. S., care of this office.

ASSAYER AND CYANIDE MILLMAN DEsires position. References. Address "Assayer," care of Mining and Scientific Press.

CAPABLE ENGINEER OF GOOD STANDING and experience would like to purchase an interest in an established engineering business—mining or civil. Only a business capable of expansion and doing high grade work is desired. Address "Experience," care of Mining and Scientific Press.

CYANIDE CHEMIST AND ASSAYER, TEN years South African and Colorado experience; had also charge of cyanide and amalg mills; at present engaged in assay office, wants change of position. Excellent references. S.A.C., this office.

EXPERIENCED ANALYTICAL CHEMIST. Assayer and Millman desires position. Address H. T. S., this office.

FIRST-CLASS METALLURGICAL CHEMIST and Assayer desires position. Can furnish best of reference, etc. Address C. W. L., this office.

FIRST-CLASS MINING AND LAND SURveyor, Draughtsman, etc., desires position. Address H. W K., Box 74, Long Beach, Wash.

MECHANICAL ENGINEER—HAVE A UNIversity education and am an all around practical mechanic. Four years experience in steam and hydraulic engineering; have designed an up-to-date blast furnace; have been connected with large copper mine for two years; good references. Prefer large gold or copper mine; foreign country preferred. Address A. B. C., care Min. & Sci. Press.

MINE SUPERINTENDENT WANTS POSITION with a substantial company that has a mill on property. A qualified mining engineer who can run a mine or mill, cyanide plant, assaying and surveying. Address "Mining," this office.

HELP WANTED.

Required for Copper Mines in Arizona

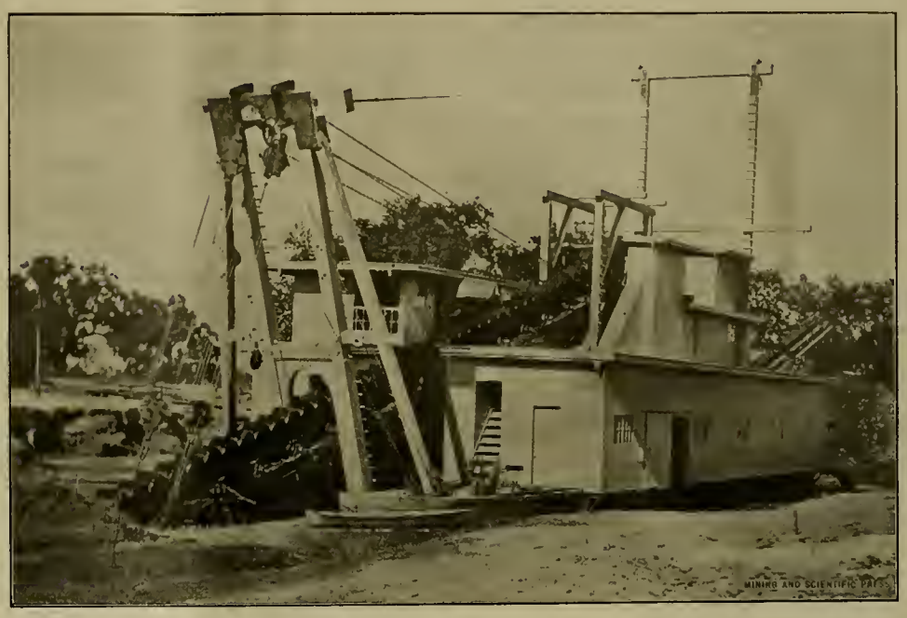
employing about 250 men, young mining engineer of good technical education and some experience in mining and mechanics, to act as assistant to superintendent. Address SHANNON COPPER CO., Clifton, Ariz.

MINING AND SCIENTIFIC PRESS.

Whole No. 2243.—VOLUME LXXXVII. Number 3. SAN FRANCISCO, CAL., SATURDAY, JULY 18, 1903. THREE DOLLARS PER ANNUM. Single Copies, Ten Cents.

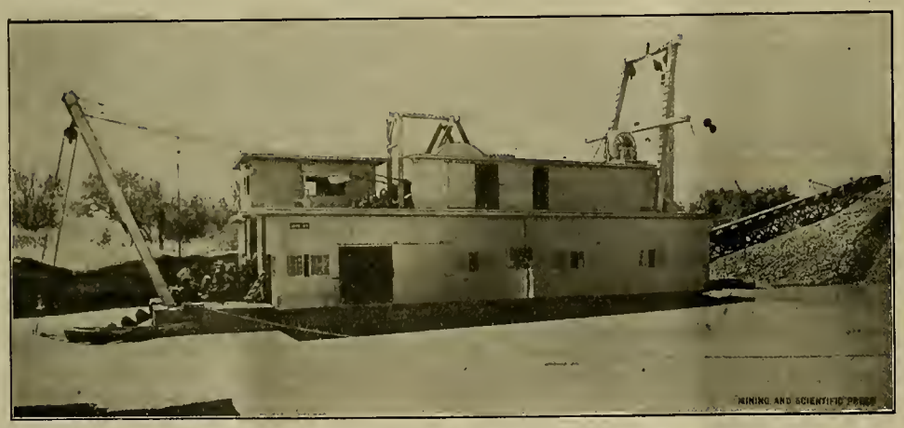
The Art of Diamond Cutting.

The cutting and polishing of diamonds is an art requiring great skill and sound judgment. It is accomplished by means of steel horizontal wheels or plates upon which there are small lines or grooves radiating from the center. On this is placed a paste of diamond dust and olive oil. The grinding is done by setting the diamond in cement, and fixing it in the proper position in contact with the wheel, which is run at about 4000 revolutions per minute. Polishing is effected in much the same manner, but with impalpable dust. It requires weeks and months to cut diamonds, and in some instances has required years to complete the task. All diamonds are not perfect as they come from the mines. Some are covered with a hard, dull coating which must be removed. Often the stones are unsymmetrical in form; discolorations, flaws and spots are frequently included, and it is the business of the lapidary to judge how any particular stone will cut to the best advantage. All diamonds have cleavage, and it is usually possible to split diamonds of distorted shape in such manner that one or more good sized stones and possibly several small ones may be obtained. When it is desired to split or cleave a stone the lapidary examines it closely, and experience tells him the proper plane upon which the delicate feat may be accomplished.



The cleaving of a valuable gem requires not only good judgment and skill, but also good nerve, for in some cases the reputation of the workman may be made or ruined by the result. The splitting is performed by embedding the diamond in cement up to a line about even with the plane upon which it is desired to remove a portion, the workman having previously scratched a line about the stone with another diamond, just where he desires to produce the fracture. He then places a steel knife blade against the diamond, holding it firmly at the proper angle, and strikes the blade a sharp blow with a light iron rod, and the work is done. The result, it is needless to say, is not always perfectly satisfactory. The art of diamond cutting has developed into a science, in which the workman must possess not only superior mechanical skill, but he must also thoroughly understand the theory of light, for the dispersion and refraction of light are of vital importance in cutting a diamond.

The aim is not to secure from the rough diamond the largest stone possible, but to get a gem which will reflect the rays of light entering it in the most intense and brilliant manner. The diamond is highly cleavable in a plane parallel with the pyramidal face. Taking advantage of this fact, lapidaries split a large diamond into thin plates at the time of the coronation of Queen Victoria, and beautiful miniatures of distinguished guests were presented to them, framed in gold and the picture covered with a sheet of diamond, instead of glass.



The diamond cutters of the fourteenth century contented themselves with merely polishing the natural faces of the stone, which in perfect crystals are octahedrons, usually with convex surfaces. Stones cut in this manner rarely show the true beauty which lies within. Several noted stones of great size have been cut repeatedly, losing largely in weight with each cutting, but always gaining in value by reason of increased brilliancy. The famous Koh-i-nur (mountain of light) is an example of this.

There is in diamond cutting, as in almost every other art, deceptions great and small. One of these is the filling out of a flat diamond with other inferior material, such as rock crystal or glass. A flat diamond is cut having a flat lower surface with the dome-like upper side cut in the usual triangular facets. A pyramidal section is then cut of quartz crystal or glass, to exactly fit the diamond cap, and the two bases are joined together with gum mastic, and the stone sold for genuine diamond.

In cutting diamonds the loss from the original weight of the crystal varies greatly—from one-third to three-fourths. It may be said to average about three-fifths. Diamonds occur in the mines in a great variety of size, color and form. The principal lapidaries are in Holland, London, Eng., and Boston, Mass. The United States is at present the largest buyer of diamonds.

The Value of Mineral Land.

When the mineral in a tract of land on the public domain is sufficiently valuable to entitle the tract to be classified as mineral land it is often a perplexing question in the mind of a would-be locator. The Federal statutes of July 26, 1866, provided for the acquisition of titles to "veins of quartz or other rock in place bearing gold, silver, cinnabar or copper." The placer law, passed July 9, 1870, extended this right to include placer deposits, under the laws governing the location of placers, which includes all forms of mineral deposit, except veins of quartz or other mineral-bearing rock in place. Later in 1872 the law was further amended, and provided for the appropriation of lands containing veins or lodes of quartz or other rock in place bearing gold, silver, cinnabar, lead, tin, copper or other valuable deposits. In the matters of determining the character of lands claimed by locators the Land Department is the sole judge of the character of the land, and its decision is final. That department, in a circular of instructions issued some time since, said substantially that what constitutes a valuable mineral deposit is, whatever is recognized as a mineral by standard authorities on the subject, where the same is found in quantities and quality to render the land sought to be patented more valuable on this account than for agriculture, shall be treated as mineral.

No court would sustain a claim based on the mere occurrence of mineral in small quantities. For instance, in many places, copper, lead and quicksilver ores occur in small quantities, and are considered more as a curiosity than as a valuable mineral deposit. Such as these would not be considered "valuable" in the sense of the law. On the other hand, a deposit so low grade in mineral contents that it could not be worked at a profit at the present time by reason of location, price of the product of the mine, or for other good and sufficient reason, in a year or two may become very valuable by a change in the conditions which to-day render it practically valueless. It is unlikely, however, that the courts and the Land Department would condemn a large mineral deposit because it was at the time being too low grade to pay, for the reasons above given. But indications or traces of mineral, such as copper stains, small bunches or flakes of cinnabar, or occasional colors of gold, would not be sufficient to render the land subject to classification as mineral. Nor will the recording of a certificate of location render it mineral land, for the claim must be susceptible to proof. A tract cannot be assumed to be more valuable for mineral for the reason that it is situated in a mineral region or belt, for in such regions there is usually much land wholly without mineral values. On the whole it may be said that land may be deemed sufficiently valuable to be classed as mineral when the deposit is actually mineral regardless of its present worth, and on the other hand, the occurrence of small bunches and streaks of mineral, in fact mere indications, would not stand the test of courts.

Cost of Mine Investment.

When a mine investment is contemplated there is much that must be given consideration. In the case of a mine so situated that a small or relatively inexpensive plant will be required, and where the property will not cost a very large amount, the risk may be said to be reduced to a minimum. Take, for instance, some of the telluride gold ore deposits which lie upon or near the surface of some of the ridges in Terry's peak region of the Black Hills of South Dakota, or one of the shallower zinc deposits of the Joplin district of Missouri. In one case practically no surface mining plant is required, and the ores may be shipped to custom works, or a plant may be built for the beneficiation of the ores. In the other instance the ore may be hoisted by means of a small inexpensive hoist, and sold to reduction works near at hand or be shipped outside of the district for treatment. In either case the investment is small, the returns prompt, and the entire operation should prove eminently satisfactory.

In comparison with these instances, consider the investment which requires the outlay of several hundred thousand dollars in the first cost of property, where from four to five years or more are required to sink a shaft from the surface to the vein, as is the case in all of the deepest levels of the Rand. No company operating on the Rand deep levels considers the outlay of $2,000,000, before the mine shall have been opened sufficiently to justify a mill, an excessive investment. Then the cost of a large mill, such as an extensive mine should have, must be provided, and, unless connection with other mine workings can be made, two shafts are necessary for proper ventilation of the property.

The large capital required for the purchase, equipment and development of mines of this class, however, seem to be no obstacle in the way of securing sufficient money to float enterprises of this character. The reason for this is that there is confidence in the producing capacity of the mines. The extensive development of the several reefs of the Rand has shown that these several reefs may be depended upon to average a given tonnage and value per stated surface area—taking into consideration, also, the change in dip from those workings near the surface as related to those opened at great depth. It has been found that while some mines are decidedly superior to others, by reason of a higher grade of ore, or because of material difference in character of the ground, yet, on the whole, these mines may be depended upon to average about $10 per ton of basket when a large area is considered. The capital outlay and interest on the investment represent in most cases nearly, or quite, one-half of the ore available in a given area—say, about 200 acres. This at once reduces an enterprise of this size to a $5 proposition. That is, before any actual profit can be realized, from $2,000,000 to $3,000,000, representing the original outlay in purchase, equipment and development of the property, together with many incidental expenses, must be recovered from the operation of the mine. Thereafter any profit resulting from mining operations is net, and it is to make this distant profit that such investments are made. In mining operations it is the net result, and not altogether the size of output, that makes a mining proposition attractive to the investor. Notwithstanding all of these drawbacks, mining is popular, for the reason that no other form of investment can offer such promise or assurance of "net result" on a stated investment as can be found in a proven mine—one in which the ore is in sight, and the values exposed show a stated profit above cost of extraction, reduction and certain fixed charges for investment, sinking fund, interest and other necessary charges.

Labor Conditions in the West.

The eight-hour law passed by the last Nevada Legislature has been declared unconstitutional by the court of that State, for the reason that the text of the law does not contain the words "wherein the life, health or limb is jeopardized," which would have rendered it a sanitary measure. It was the provisions of this bill that precipitated the strike at Searchlight, where the miners are still out. Recently the owners of the mines in southern Nevada and southern California formed a combination known as the Desert Mine Operators' Association, the object of which is stated to be to "protect, foster and develop the mining industry in all its branches in the district covered by the association," and that they will not discriminate between union and non-union miners. The association numbers in its membership all of the principal operators in California south of the Tehachapi mountains, and many of those of southern Nevada.

In British Columbia, after a strike of four months, the miners, by a majority vote, have agreed to return to work under practically the same conditions as those obtaining at the time the strike was declared.

In Colorado the smeltermen are out at Denver and Colorado City, and have practically tied up several plants. The courts have issued an injunction restraining the strikers from picketing or in any manner interfering with the business of the smelters of the American Smelting & Refining Co. The strike threatens to involve the entire smelting industry of the State, and if prolonged must also seriously affect the mines as well, whether the strike extends to them directly or not, for a large portion of the mining industry of Colorado is directly dependent upon the smelters.

In Tuolumne county, Cal., a number of important mines are closed, the miners, who are members of the Western Federation, having gone on strike because of a refusal of the operators to increase wages. In Yavapai county, Ariz., numerous mines are idle, due to strikes resulting from the trouble over the eight-hour legislative day which was enacted by the last Territorial Legislature.

Canadian Lead Bounty.

The Canadian Government has authorized a bounty on lead produced and smelted in the Province of British Columbia. The miners of that section have long bitterly complained that they were working under a disadvantage of location, and made a determined effort to secure governmental assistance in the development of the large resources of the Province. The bounty as announced is 75 cents per hundredweight, or three-quarters of a cent per pound, a substantial increase over the prevailing price. The maximum amount provided for, however, is $500,000. The subsidy will be operative during a period of five years, during which time it is thought the industry may be placed on a footing which will render it self-sustaining. Should the price of lead in London go above £12 10s per ton of 2240 pounds—about $2.80 per hundred pounds—the duty shall be reduced proportionately. The English colonies in no case receive as much for their lead as do the miners of the United States. There are large silver-lead mines in the Province of British Columbia, particularly in the Slocan and Kootenay sections.

THE regeneration of cyanide solutions by various means is a subject now attracting much attention among workers in that important branch of metallurgy. This has been successfully accomplished by means of sodium sulphide, and experiments are now being made to do this electrolytically. Heretofore there has been much loss of cyanide, particularly in weak solutions and wash waters, but recent discoveries indicate that the time is not far distant when a stock of cyanide will remain in circulation for a long time, like quicksilver in an amalgamating mill, without serious loss.

CONCENTRATES.

MURIATIC ACID—hydrochloric acid (HCl)—is obtained largely as a by-product in the manufacture of soda-ash (crude sodium carbonate) by the Le Blanc process.

♣

IT is not possible to even approximately "give the annual consumption of dynamite in the mines of the United States." The Alaska-Treadwell mines, Douglas Island, Alaska, are credited with an annual consumption of 1,000,000 pounds.

♣

PHOTOGRAPHS of veins, above and below ground, of streams of water or springs, and improvements in the way of flumes, ditches, etc., and of buildings attached to a mine, are valuable accessories to a mine report, and should accompany the same whenever convenient.

♣

IN the United States sapphires have been obtained with placer gold, in gravel deposits along the Missouri river, near Canyon Ferry, Mont., but the principal mines for which are in Yogo gulch, Fergus county, Mont. North Carolina and Georgia also produce sapphires.

♣

MICA SCHIST is sometimes gold-bearing, though such deposits are very irregular in shape and values scattered. When a mica schist or a mica slate becomes gold-bearing to any considerable extent, the rock is usually more siliceous than the normal rock. The mica then often disappears.

♣

IT IS erroneous to presume that the dipping needle, often employed in the search for hidden iron ore, will show its greatest deflection when directly over the greatest mass of the ore deposit. The magnetic attraction is always found to be greatest at a point to the northward of the south pole of the deposit. Another fact not to be neglected in the use of the dipping needle is that a small mass of iron near the surface may exercise as great an influence on the needle as a larger mass at a greater distance below the surface.

♣

"DIP" in mining parlance, in mining law and geology, means the departure of a vein in its downward course, from the vertical or the horizontal. It is usually measured in degrees of arc from the horizontal. Thus a vein said to dip 80° stands nearly vertical and not almost flat. The dip of a vein or of strata is at right angles to its strike. In a vein having a sinuous course both strike and dip will be variable in direction, but the angle of dip may be uniform. It is the privilege of a claim owner to follow this "dip" of the vein beyond the side lines of the claim that is known as the extralateral right.

♣

BLANKET CONCENTRATION in one form or another has long been practiced. Bullock and other hides were employed for this purpose before blankets. Mats, carpets and other fabrics were used for the same purpose. The employment of canvas in concentration of slimes is of comparatively recent origin. It has been in use in California for twenty years or more. Old canvas is said to concentrate slimes more satisfactorily than new, for the reason that the roughness of new canvas catches a larger amount of sand. With the operators of canvas plants it is always a question of loss by fine material passing over, or loss by catching too much sand.

♣

THE carat is the unit of weight in valuing gems, and is equal to 3.2 grains in New York and 3.7 in London, varying according to different authorities. The international carat is 3.168 grains. The term originated in the division of a gold mark (coin) into twenty-four equal parts. It is also used to denote the proportion of gold in an alloy. Thus eighteen carats fine means that the alloy contains eighteen parts gold and six parts other metal, usually silver or copper, or both. There is no difference between grains avoirdupois or grains troy, but there is a difference in the avoirdupois ounce and the troy ounce. The avoirdupois ounce contains 437½ grains and the troy ounce equals 480 grains. An avoirdupois pound contains 14 58 troy ounces.

♣

A WINDLASS for prospecting work should have the winding cylinder long enough or of sufficient diameter to accommodate all the rope required to sink to the desired depth, without overlapping on the drum. A shaft may be sunk with windlass to 100 feet deep and more by putting four men on the cranks, but it is doubtful if windlassing is profitable below 70 feet. For long lifts a geared windlass is sometimes employed. It is customary to substitute a whip or whim run by horse power for a windlass when the shaft becomes too deep for windlassing, and it is not desirable or expedient to put in a power hoist. The so-called "pig tail" hook is not a safe device for men to work under, nor is a loop in the rope passed through the ring in the bale of the bucket and secured by a stick more so. A safety hook is the best device where it is necessary to detach the rope from the bucket below or above ground.

♣

THE United States Statute, Section 2320, provides mining claims upon veins or lodes of quartz or other rock in place, bearing gold, silver, cinnabar, lead, tin, copper, or other valuable deposits, heretofore located, shall be governed as to length along the vein or lode by the customs, regulations and laws in force at the date of their location. A mining claim located after May 10, 1872, whether located by one or more persons, may equal, but shall not exceed, 1500 feet in length along the vein or lode, but no location of a mining claim shall be made until the discovery of the vein or lode within the limits of the claim located. No claim shall extend more than 300 feet on each side of the middle of the vein at the surface, nor shall any claim be limited to less than 25 feet on each side of the middle of the vein at the surface, except where adverse rights existing on May 10, 1872, render such limitation necessary. The end lines of each claim shall be parallel to each other.

♣

THE spitzkasten is a device of German origin employed to effect a separation of fine from coarse ore and gangue by hydraulic method. It consists usually of a rectangular, sometimes square box, having a pointed bottom. The material to be sized enters through a launder at the top and the coarse passes out at the bottom, the fine flowing out near the top. The spitzlutte, also a hydraulic classifying device, generally consists of two inverted cones, one within the other. The pulp to be sized enters the inner cone, the coarse passing out at the bottom, as in the spitzkasten; but an upward current of water causes the slimes to remain longer in suspension, and thus effects a more complete separation of fine from coarse material. The fine slimes pass upward in the space between the two cones and flow away through a launder. Both the spitzkasten and spitzlutte have a variety of forms, but the principles employed are similar throughout.

♣

BORNITE—eruhescite, "horseflesh ore," peacock copper—is a sulpide of copper and iron (Cu_3 FeS_3), brittle, hardness = 3, specific gravity = 5, metallic luster, color between copper-red and "pinchbeck brown" on fresh fracture, but quickly iridescent from tarnish. Analyses of massive varieties show 50% to 70% copper and 15% iron. It is distinguished by its peculiar reddish color on fresh break and by its brilliant tarnish. Chalcopyrite (Cu FeS_2) also often shows an iridescent tarnish, but on fresh fracture is brass-yellow. Bornite before the blowpipe becomes magnetic. Bournonite is a sulph-antimonate (Ph Cu SbS_3), carrying 25% antimony, 42% lead and 13% copper. It is brittle, with brilliant metallic luster, and steel-gray, inclining to blackish lead-gray color. It is also called "wheel ore," from the twining action, forming cruciform and wheel-shaped crystals. On charcoal, with blowpipe, the residue treated in reducing flame with soda gives a globule of copper.

♣

THE Great Basin is a large area of territory lying east of the crest of the Sierra Nevada mountains of California and high mountains in eastern Utah. It includes nearly all of the State of Nevada, three-fourths of northern and western Utah, a portion of southeast Oregon and southwest Idaho, a narrow strip along eastern California and a large portion of southern California, known as the Mojave and Colorado deserts, and extending into Lower California. This vast territory covers an area of about 210,000 square miles and does not drain into any ocean, the entire drainage being absorbed or evaporated. The average rainfall is stated to be about 7 inches per annum. It is estimated that the annual evaporation of the Great Salt lake in Utah is about 80 inches. If it were not for the rain and snow fall tributary to that body of water it would in the course of a few years cease to be a living lake and would appear as a dry lake. The Great Salt lake is merely a remnant of a once greater lake known to geologists as Lake Bonneville. It was at least five times as large as the present Great Salt lake.

♣

TURQUOISE is a hydrous phosphate of aluminum, colored by copper. It occurs in veinlets and bunches of irregular size and form, usually in lava rocks, particularly the trachytes, sometimes in altered clay slates. It is sky blue, greenish blue, or apple green in color, often greenish gray. The pure sky blue is the most highly prized. The fracture of this mineral is small conchoidal, hardness about 6, and is brittle. It has a somewhat waxy luster. Turquoise occurs in the Los Cerrillos mountains, near Santa Fe, and in the Burro mountains, Grant county, New Mexico, several localities in Arizona, California and Nevada. Chrysocolla, a silicate of copper, is sometimes mistaken for turquoise, which it resembles in color. It has a conchoidal fracture, but is much softer than turquoise, being 2 to 4, and is readily scratched with a knife. The streak is white when pure. Chrysocolla contains silica 34.3, copper oxide 45.2 and water 20.5, there being no aluminum. It is in some localities an important ore of copper. It often accompanies other ores of copper and is undoubtedly a product of the alteration of copper sulphides.

♣

CUPELS are made from bone ash generally, though other substances, notably magnesite, have been successfully employed in cupel making. Experience has proven that the bones of horses or sheep make the best bone ash for this purpose. This ash consists principally of calcium phosphate, with some carbonate and a little fluoride of calcium. It is prepared by burning the bones until they become white, though care should be taken not to overheat the bones. The bone ash must then be pulverized, sifted and washed several times with boiling distilled water, until all soluble salts are removed. The finest particles of the ash will remain longest in suspension in the wash waters. These must be allowed to settle separately, and may be used in giving a final coating to the cupel. The cupel mold is filled with the moistened ash and the pestle hammered down to compress the ash into a solid cake. The pestle is then turned around to smooth the surface of the cupel. The pestle is then removed and a small quantity of the fine ash sifted over it, and the pestle again hammered into the mold. Care must be taken, however, not to compress the cupel too tightly or it will to a great extent lose its absorbent power and become useless. Cupels should be thoroughly dried before using—at first under a low heat, which may later be increased, finishing, if need be, in the muffle of the furnace.

♣

THE great danger involved in a "missed hole" is in the men who put in the shot being tempted to go to it, if it does not go off after a certain time, and tinker with it, and the shot may not have actually missed, but be smoldering, and go off while they are near. It is always claimed by electrical men that an electrically fired shot is safe to approach, immediately after the attempt has been made and has failed, but from the reports of the mines inspectors this does not appear to be correct. Ore nor coal are not like a cannon, though the action of a shot, which properly performs its work, is exactly like the action of a charge of powder fired in a cannon, the only difference being that the force of the explosion is expended in shattering the coal or ore instead of in expelling the shot. When the shot fires, but does not shatter the coal, or the rock it is intended to bring down, the action is similar to the firing of a blank charge from a cannon, the shot hole forming the barrel of the gun. It sometimes occurs that the explosive has not the full power it is supposed to have, owing to proper materials not being used, or to its having deteriorated, and it also sometimes happens that there are cracks in the coal or rock, especially when the shot is not fired immediately, and the squeeze from the overlying strata has time to operate, and in those cases the shot may be blown out, or it may be expended uselessly, but with danger to the attendants, in the cracks, etc., and may be smoldering.

♣

WHERE land is located on the public domain as placer, known lodes or veins are excepted and cannot be included by the placer claimant. What constitutes a known vein or lode has been made clear by the Supreme Court of the United States, says "Lindley on Mines." Where a vein or lode location has been made under the law, and its boundaries have been specifically marked on the surface so as to be readily traced, and notice of the location is recorded in the usual books of record within the district, it may be safely said that the vein or lode is known to exist, although personal knowledge of the fact may not be possessed by the applicant for placer claim. The information which the law requires the locator to give the public must be deemed sufficient to acquaint the applicant with the existence of the vein or lode (Noyes vs. Mantle, 127 U. S., 348), but a valid lode location can only be predicated on a discovery of a vein of quartz or other rock in place carrying valuable deposits sufficient to justify the expenditure of time and money for its development, and such discovery must be shown before the location notice or its record will possess any force as against a placer claimant. * * * The knowledge of the existence of a lode is not presumed from the mere production of a recorded notice ante-dating the location of the placer." It is plainly the intent of the law not to include any lode or vein, the existence of which was previously known, but not considered worth locating. The mining law also gives claim holders the right to cut timber on their claims for their own domestic use, mining purposes, etc.

♣

MICA is usually not difficult of determination if the scales are large enough to be distinctly seen and handled by the point of a knife. There are several varieties of mica, some of which have commercial value when in merchantable condition. The most common is muscovite, or potash, mica. This is the ordinary mica of commerce. By transmitted light it is various shades of yellow, green and brown, wine color, etc. It is an essential constituent of gneiss and granite and is sometimes found in quartz-porphyry, but never in other eruptive rocks. Phlogophite is a magnesian mica having a pearly luster and is often sub-metallic on the cleavage faces; color yellowish brown and brownish red, with copper-like reflections. When a small candle flame is viewed through thin plates of this variety of mica it shows commonly a six-rayed star. Phlogophite occurs mostly in the older crystalline rocks, such as Archæan granular limestone. Margarite, or pearl mica, is tabular, scaly or massive, and, unlike other micas, is brittle. In color it is white, grayish, reddish, yellowish, sub-translucent. It is commonly found with corundum. It is a lime-alumina mica. Biotite is the black, brown or green, dark-colored iron-magnesia mica. It occurs commonly in many rocks—in diorite, some volcanic rocks, and more rarely in granite, not uncommon in grano-diorite. It is completely decomposed by sulphuric acid. It is more abundant in acid than in basic rocks. Margarodite, a talc-like mica, though not a magnesian mica, is scaly to granular, and has a bright, pearly, sub-metallic luster. It is a variety of muscovite. Sericite is a fine, scaly muscovite, united in fibrous aggregates, and is characterized by its silky luster. Lepidolite is lithia mica. It occurs in plates and granular masses, coarse or fine; luster pearly, color rose red, violet gray, lilac, yellowish white. It occurs in granite, gneiss, and particularly in granitic veins of coarse crystallization.

Approximate Data of Open Streams, Weirs, Pipes, Etc.

Written for the MINING AND SCIENTIFIC PRESS by F. S. BECKETT.

The conventional formula or table, while indispensable, is at best fragmentary, often requiring much labor and calculation to complete the story. This may not be a serious matter to the student with time and a reference library at his command but to the practical man in the field facts and conclusions receive an added value from the ease and promptness with which they can be secured. The accompanying graphic table is an attempt to give in a form suitable for ready reference the results and conclusions of the formulæ most often required in the line of work indicated by the title.

A good way to use the table, for one sufficiently interested, is to form a strong mental picture of the various curves and scales. It is then surprising with what ease problems can be solved off-hand and with fairly accurate results.

As it is only intended to give approximate results, small losses have not been taken into account. No allowance has been made for strong head winds, evaporation or leakage. Hydraulic riveted pipe, being used to such great extent, is alone considered and is supposed to be clean, free from short ourves and valves, and with a perfectly shaped taper and nozzle.

The following problems are given to show the scope and application of the table:

Example 1 (indicated by heavy dotted lines).—An open stream is found by measurement to have an area of 3 square feet. Chips dropped on the surface float at an average velocity of 96 feet per minute. It is proposed to conduct the water across a deep ravine through 900 feet of 14-inch riveted pipe; thence through a ditch 3 feet wide by 1 foot depth of stream, through good, solid earth to a penstock; thence down 160 feet through 700 feet of similar pipe to a wheel rated at 85% efficiency, which wheel is to be belted to a compressor rated at 40% efficiency.

1. What is a rough estimate of the quantity of water by means of the chips?

Start from 96 feet, "Velocity at Surface," thence down obliquely left to 80 feet, "Velocity Feet per Minute;" thence vertically up to 3 feet, "Area Stream;" thence horizontally left to 240 feet, "Quantity Cubic Feet per Minute," or 160 "Miner's Inches." Ans. 1.

2. If this quantity is correct, what should be the depth of stream of a quadrantal weir?

Start from 240 feet, "Quantity Cubic Feet per Minute," thence down obliquely right to 14 inches, "Depth Quadrantal Weir." Ans. 2.

3. What should be the depth of stream of a 26-inch rectangular weir with contraction suppressed?

Start from 240 feet, "Quantity Cubic Feet per Minute," thence horizontally right to a point vertically down from 26 inches, "Width Rectangular Weir, no Contraction," which point is on 8 inches "Depth Rectangular Weir." Ans. 3.

4. What should be the difference between the levels of the two streams?

Start from 240 feet, "Quantity Cubic Feet per Minute," thence horizontally right to 14-inch "Riveted Pipe;" thence vertically down to 900 feet, "Length Pipe;" thence horizontally left to 4½ feet, "Actual Head Open Pipe." Ans. 4.

5. Give the limits of the velocity in the ditch that would prevent a growth of vegetation and at the same time not erode the banks.

"Earth in Good Order — Limiting Velocities = 1 foot to 2½ feet." Ans. 5.

6. Give the proper grade for the proposed ditch.

Start from 160 "Miner's Inches," thence horizontally right to 3 feet "Area Stream;" thence vertically down to "Earth in Good Order;" thence horizontally left to "Area ÷ Wet Perimeter = .6" $\left(\text{or } \frac{3}{3+1+1} = .6\right)$; thence vertically down to 1⅛ inch, "Grade Inches per 100 Feet;" or ⅛+ inch, "Grade Inch per Rod." Ans. 6.

7. Give the corresponding average velocity.

Start from 1⅛ inch, "Grade Inches per 100 Feet;" thence vertically up to "Area ÷ Wet Perimeter = .6;" thence horizontally right to "Earth in Good Order;" thence vertically down to 80 feet, "Velocity Feet per Minute," or 1⅓ foot, "Velocity Feet per Second." Ans. 7.

8. What will be the friction head of the pipe leading to the wheel?

Start from 160 "Miner's Inches," thence horizontally right to 14-inch "Riveted Pipe;" thence vertically down to 700 feet, "Length Pipe;" thence horizontally right to junction; thence down obliquely left to 3½ feet, "Friction Head Closed Pipe." Ans. 8.

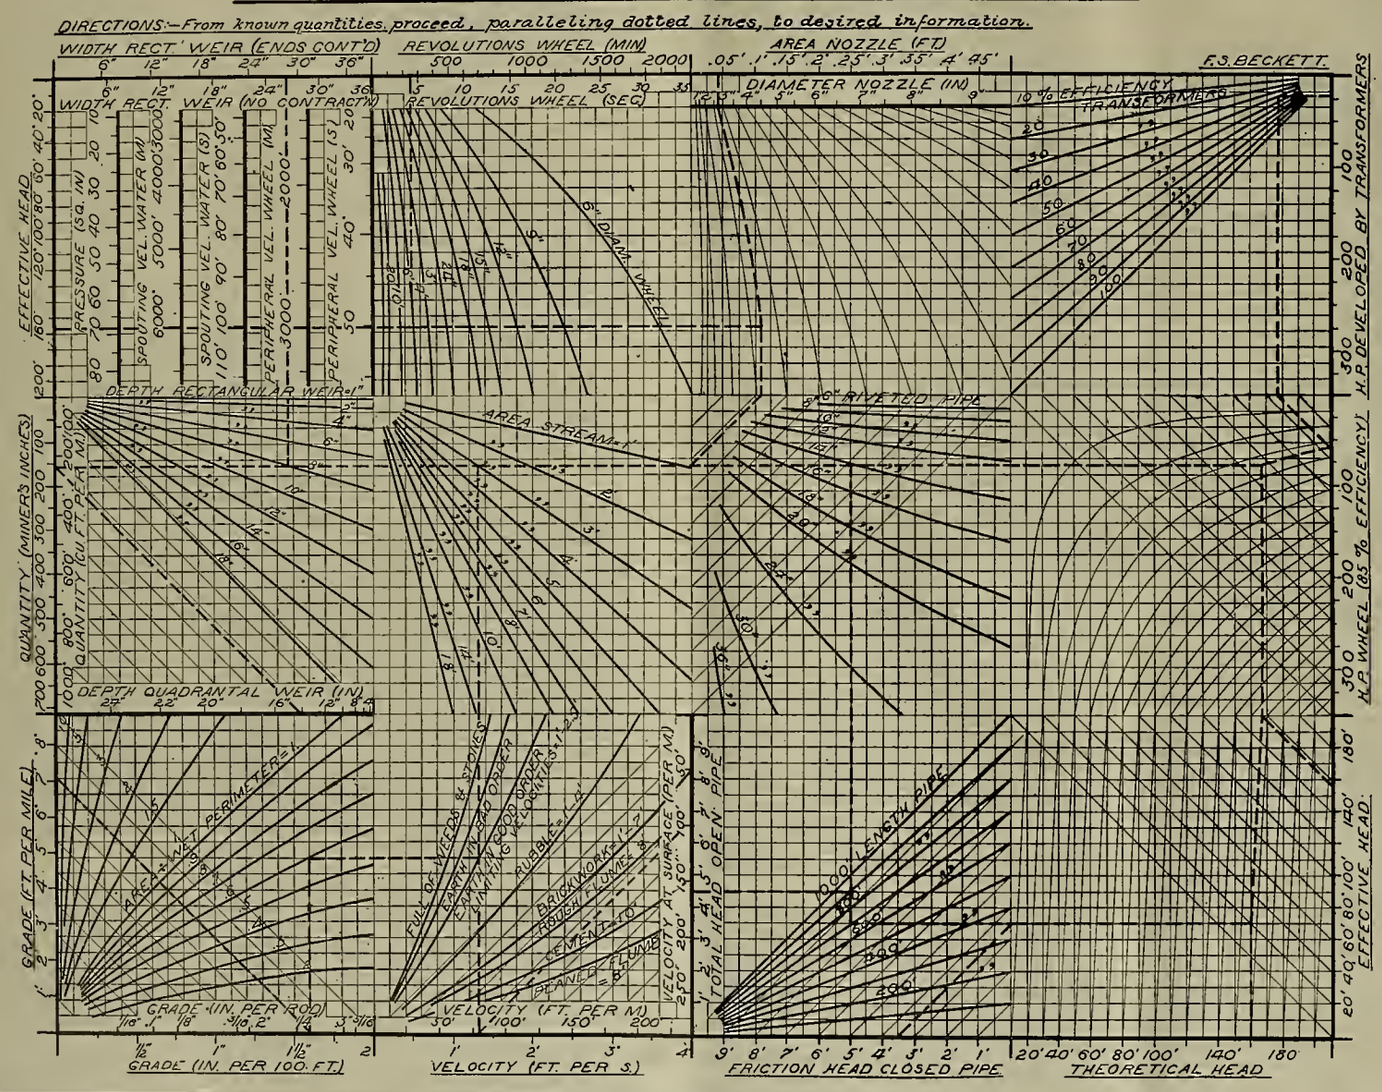
9. Give the effective head of the same pipe.

Start from 3½ feet, "Friction Head Closed Pipe," thence up obliquely right to junction; thence horizontally right to a point vertically up from 160 feet, "Theoretical Head;" thence up obliquely right to end of oblique section lines; thence down obliquely right to 156½ feet, "Effective Head." Ans. 9.

10. Give the H. P. developed by the water.

Start from 156½ feet, "Effective Head," thence up obliquely left to end of oblique section lines; thence vertically up to a point horizontally right from 160 "Miner's Inches;" thence up obliquely right parallel to curved section lines to 60 "H. P. Wheel." Ans. 10.

11. What should be the effective H. P. of the compressor?



Start from 60 "H. P. Wheel," thence up obliquely left to end of oblique section lines; thence vertically up to 40%, "Efficiency Power Transformers;" thence horizontally right to 24 "H. P. Developed by Transformers." Ans. 11.

12. What will be the pressure of water when the wheel is running?

Start from upper left corner at 156½ feet, "Effective Head," thence horizontally right to 68 pounds, "Pressure per Square Inch." Ans. 12.

13. What spouting velocity corresponds to that head?

Start from 156½ feet, "Effective Head," thence hori-

zontally right to 6000 feet, "Spouting Velocity Feet per Minute," or 100 feet, "Spouting Velocity Feet per Second." Ans. 13.

14. What should be the peripheral velocity of the wheel?

Start from 156½ feet "Effective Head," thence horizontally right to 3000 feet, "Peripheral Velocity Wheel Feet per Minute," or 50 feet, "Peripheral Velocity Wheel Feet per Second." Ans. 14.

15. What diameter wheel should be used to give 250 revolutions per minute?

Start at 156½ feet "Effective Head," thence horizontally right to a point vertically down from 250 "Revolutions Wheel per Minute," which point is on 4 feet "Diameter Wheel." Ans. 15.

16. What diameter nozzle ring should he used?

Start from 156½ feet, "Effective Head," thence horizontally right to a point horizontally right, then up obliquely right, then vertically up from 160 "Miner's Inches;" thence up obliquely left, parallel to curved section lines to 2⅝ inches, "Diameter Nozzle." Ans. 16.

Answers may be found to problems relating to open streams varying in sectional shape, size and character of bed.

Problem 2.—A rough plank flume 4 feet wide by 2 feet depth of stream is given a grade of 4.75 feet per mile. What will he the velocity?

Solution.—Start from 4¾ feet, "Grade Feet per Mile," thence down obliquely right to 1.1 inch, "Grade Inches per 100 Feet;" thence vertically up to "Area ÷ Wet Perimeter" = 1; thence horizontally right to "Unplaned Plank;" thence vertically down to 3.8 feet, "Velocity Feet per Second," or 228 feet, "Velocity Feet per Minute." Ans.

By extending curves and scales the range of the table may be increased by a rough guess.

Problem 3.—If, in problem 1, a 12-inch pipe is used, what will he the friction head?

Extend curve "12-inch Riveted Pipe" to a point horizontally right from 160 "Miner's Inches." Extend line "700 feet Length Pipe" to a point vertically down from point 1; thence horizontally left to beginning of oblique section lines; thence down obliquely left to 7½-feet, "Friction Head Closed Pipe." Ans.

The following formulæ and rules of proportion, taken for the most part from Kent's "Mechanical Engineering" and Randall's "Practical Hydraulics," include those used in the preparation of the table, with the addition of others which may he used to increase its range or seoure greater accuracy for extreme quantities:

Rectangular weir, no contraction:

$$q = 3.33\, l\, h^{\frac{3}{2}};$$

$$q : q_{,} = l : l_{,}.$$

Rsctangular weir, full contraction:

$$q = 3.33\,(l - .2h)\, h^{\frac{3}{2}};$$

$$q : q_{,} = l : l_{,}.$$

Quadrantal weir:

$$q = 2.6365\, h^{\frac{5}{2}}.$$

Friction water in pipe:

$$f = \frac{l\,(4\,v^2 + 5\,v - 2)}{1000\,D}; \qquad \text{(Cox.)}$$

$$f.\ f_{,} = l : l_{,} = v^2 : v_{,}^2 = q^2 : q_{,}^2;$$

$$q : q_{,} = a : a_{,} = d^2 : d_{,}^2;$$

$$h' = h - f;$$

$$q = v\,a.$$

Pressure water:

$$p = .434\,h;$$

$$h = 2.3\,p;$$

$$p : p_{,} = h : h_{,}.$$

Spouting velocity water:

$$v = \sqrt{2\,g\,h'} = 8.02\sqrt{h'};$$

$$v : v_{,} = \sqrt{h'} : \sqrt{h'_{,}}.$$

Perlpheral velocity wheel:

$$v = .5\,\sqrt{2\,g\,h'} = 4.01\,\sqrt{h'};$$

$$v : v_{,} = \sqrt{h'} : \sqrt{h'_{,}}.$$

Revolutions wheel:

$$r\,c = .5\sqrt{2\,g\,h'} = 4.01\sqrt{h'};$$

$$r : r_{,} = d_{,} : d.$$

Nozzle ring:

$$d = \sqrt{\frac{a}{.7854}};$$

$$a = d^2 \times .7854 = \frac{q}{\sqrt{2\,g\,h'}};$$

$$q = a\sqrt{2\,g\,h'} = 8\,02\,a\sqrt{h'};$$

$$q : q_{,} = a : a_{,} = d^2 : d_{,}^2 = D^2 : D_{,}^2.$$

Open streams:

$$v = \left\{ \frac{\frac{1.811}{n} + 41.6 + \frac{.00281}{s}}{1 + \left(41.6 + \frac{.00281}{s}\right)\frac{n}{R^{\frac{1}{2}}}} \right\} (R\,s)^{\frac{1}{2}}; \quad \text{(Kutter.)}$$

$$v = .83\,v'.$$

Horse power water:

$$\text{H. P.} = .284\,h'\,i\,e = .00189\,h'\,Q\,e = .000031\,H\,q\,e = \frac{62.5\,Q\,h'\,e}{33{,}000} = \frac{62.5\,q\,h'}{550};$$

$$\text{H. P.} : \text{H. P.}_{,} = h' : h'_{,} = q : q_{,} = Q : Q_{,}.$$

Horse power developed by power users:

H. P. = H. P. water × e power users.

Safe thickness iron riveted pipe:

$$t = \frac{p\,D}{5000 \text{ to } 8000}.$$

1 cubic foot water = 62 5 pounds = 7.48 gallons = ⅔ miner's inch.

1 miner's inch = 93.75 pounds = 11.22 gallons = 1½ cubic foot per minute.

Notation:

a = area—feet.
c = circumference—feet.
d = diameter—feet.
D = diameter—inches.
e = efficiency.
f = friction head—feet.
g = 32.16.
h = head—feet.
h′ = effective head—feet.
H. P. = horse power.
i = miner's inches.
l = length—feet.
n = coefficient of roughness of stream bed.
.009 = planed lumber, perfect order.
.010 = cement.
.012 = unplaned wooden flumes.
.013 = brickwork.
.015 = canvas lining.
.017 = rubble, also earth in highly regular cases.
.020 = coarse rubble, set dry in bad condition, very firm, regular gravel.
.0325 = dry, coarse rubble in bad order; earth canals and channels above average.
.025 = earth, canals and channels in good order.
.030 = earth, canals and channels in bad order.
.035 = rivers and canals in bad order, overgrown with vegetation and strewn with stones.
.070 = rivers in earth, with stones and weeds in great quantities.
p = pressure per square inch.
q = quantity—cubic feet per second.
Q = quantity—cubic feet per minute.
r = revolutions per second.
R = hydraulic mean depth = area / wet perimeter.
s = sine of slope.
t = thickness—inches.
v = average velocity—feet per second.
v′ = velocity at surface—feet per second.

Problem 4.—If, in problem 1, 50 revolutions were required, what should he the new diameter of the wheel?

Solution by proportion:

$$d : d_{,} = r_{,} : r \text{ or } d_{,} = \frac{dr}{r_{,}} = \frac{4 \times 250}{50} = 20 \text{ feet}$$

diameter. Ans.

Solution to problem 2 by formula:

$$v = \left\{ \frac{\frac{1.811}{n} + 41.6 + \frac{.00281}{s}}{1 + \left\{41.6 + \frac{.00281}{s}\right\}\frac{n}{R^{\frac{1}{2}}}} \right\} (R\,s)^{\frac{1}{2}}$$

$$= \left\{ \frac{\frac{1.811}{.012} + 41.6 + \frac{.00281}{.0009}}{1 + \left\{41.6 + \frac{.00281}{.0009}\right\}\frac{.012}{1^{\frac{1}{2}}}} \right\} (1 \times .0009)^{\frac{1}{2}} = 3.8$$

velocity feet per second. Ans.

Hand vs. Machine Drilling.

In the mines of the Rand the subject of machine vs. hand drilling has received much attention. The conclusion reached there is that where circumstances are favorable, machine drilling in the stopes is carried on with considerable success. In narrow stopes, however, time is wasted in the frequent shifting of the drill, and unless the hanging and footwalls are extremely hard, there is the drawback of the greater amount of waste country rock brought down by the heavier blasting charges used; and this, combined with the larger amount of fines produced, which cannot be sorted, has a detrimental effect on the milling returns. Where the stopes are fairly wide and the dip flat, however, a great saving can he effected by the use of machine drills.

Mining With Machine Drills.

NUMBER II—CONCLUDED.

Written for the MINING AND SCIENTIFIC PRESS by E. L. LE FEVRE.

Where a number of machines are running it is advisable to have an assortment of bars. One man may require one 3½ feet long for a horizontal set up; another may find a 9-foot support none too long for a vertical position.

The simple bar with a jackscrew in one end is preferable to the column of fixed dimensions set upon a jack block with double screws for all stoping work.

In filled stopes the tripod is an unmitigated nuisance. In square-setted stopes too wide for bars they can he tolerated. The use of an arm to the bar is seldom required for big machines in stopes, as they are powerful enough to drive a heavy bodied drill across hard rock diagonally after the hole is properly started, and the runner knows his business.

In setting up the machine the judgment of the runner is shown more than in any other work on a machine. Peculiarities of vein structure, direction of slips and contour of intrusions, must he carefully noted and advantage taken of all favorable conditions. All blocking should be of sound, tough timber, reasonably free from knots. Sawed wedges are preferable. They should he 1 foot long and of varying widths and thickness at butt end. Blocking faced on one side and rounded on other answers very well, the rounded side being placed next the bar shoe. Blocking should he confined to one end of the bar if possible, preferably to the jacking end, a wide wedge or 2-inch piece properly wedged answers nicely for the opposite end. The blocking and plank should fit squarely on the shoes; if necessary the bar should he deflected to meet this requirement. Wet, slimy surfaces should he scored with a moyle or pick to roughen the face so as to give holding power and prevent wedges slipping.

In filled stopes the vertical set-up is to he preferred for many reasons. The bar may be slanted to meet inequalities in the roof: cleavage planes in fissures are apt to parallel the walls; handling machine is facilitated by it. Great care should he taken to avoid extremely hard or soft masses at angles impossible to drill. A vertical set-up allows small latitude laterally to correct deflections of the drill, yet a careful inspection of the vein mass will usually admit of locating the machine so that small inconvenience therehy results and a six-round hole in an 8-foot breast may he readily drilled in a shift. In setting up on the edge of slanting declivities in the stope the hottom timbers used for blocking should be laid parallel with the walls of the vein. Where rock sustaining walls are built they must he carefully laid and each course filled in with fine stuff to prevent uneven settling. By using precautions in preparation a great many mishaps can he avoided and the annoyance of having a machine fall down rendered impossible. In "jacking up" the bar it is better to do it a little at a time, thus giving the ruhble end a chance to settle and avoid splitting the foot block by applying too much pressure at one time.

Having secured the machine in the proper position, about two ounces of oil may he poured into the hose, gaskets (those made of fuse are good) inserted and the hose tightly connected with the machine. The runner should then go carefully over the machine, inspecting every nut and holt. Nine out of ten breakages of crossheads, feed screws and shell rods are due to neglect in not tightening rods properly. In drilling a round of holes the ground to he broken should he carefully inspected, and the physical characteristics noted in minute detail. An observance of this rule will benefit any machine runner, no matter how long he has been at the business, as it gives one a good idea of the salient features of vein structure and affords a hasis for reasoning when locating the set-up.

By breasting is hy far the most desirable method of carrying a stope, and to keep it properly faced requires not a little judgment of angles and distance. Here again is where a vertical set-up has superior advantages in allowing the proper pitch to be given the holes and permit a correct vertical spacing. Where water is difficult to obtain this is a very important point. Again, all machines necessarily have some play in the shell; this is at a minimum where the edge of the guides hears the strain. In starting holes at angles there is always a tendency for the drill to deflect in some direction, generally with the slant of the face; the upright bar makes it easy to correct this tendency.

The holes on opposite sides of the vein should he pitched at different angles from a common plane. This minimizes the chance of one hole shooting out another. Each and every hole should have a correlative value to all the others.

It is a difficult matter to start a hole in hard rock where the face plane is not at a right angle with the drill bit; this may usually be overcome by lowering the machine on the bar and changing the pitch, drilling a few inches, then raising the machine and catching the edge of the hole thus started. In soft rock, holding the shank of a drill against the face, shorten-

ing the stroke and using the least possible power at first, will accomplish the desired end.

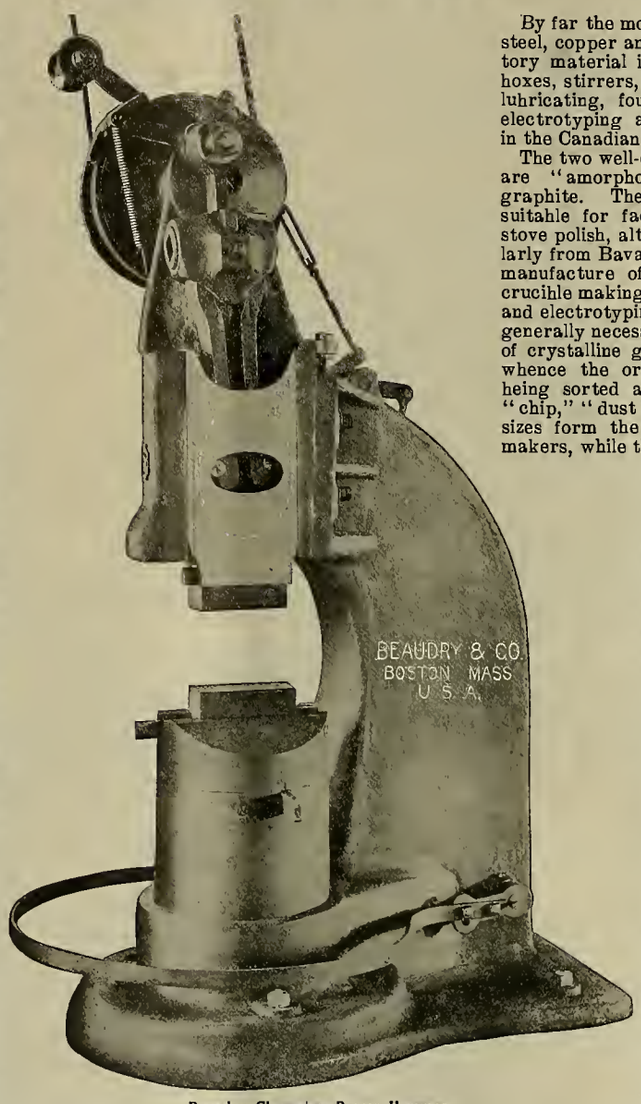
Having started a hole free from rifling, great care should be taken to keep it straight, deflections in any direction should he met by promptly changing the adjustment. Too much stress cannot he placed upon this feature of machine work, for therein lies a cardinal secret of successful machine operating. Many a "failure" may know all about a machine, and be posted on the tricks of drilling, yet never be able to put in a symmetrical round of holes because of negligence, laziness or ignorance of this vital point.

The first drill used should be sharp, with a hig full length harrel, and perfectly straight. By leaving the weld unswaged the joint of body and barrel steadies the drill after it once gets heyond the collar of the hole. Beware of using slender-hodied, nuhbitted drills in starting holes in hard rock where difficulties are to he expected. A tendency to rifle should he met at once hy changing the stroke length and increasing the power. If the drill is even slightly dulled put in a sharp one.

In case a hole runs off, the machine should he moved in the direction the drill deflects until the harrel rests on the side of the hole; this gives a long hearing and makes it possible to cut into a harder stratum of rock at an ohtuse angle. When a drill sticks in a hole and fails to clear itself when struck hy the chuck wrench, it should he taken out at once and the cause investigated. More machines are broken hy reckless pounding in trying to force a drill than hy any other thing. If a drill is used too long and the next length won't go to the hottom of the hole hy a few inches, it may he made to work hy inserting the shank into the chuck, cranking up close, turning on power without tightening the chuck nuts and driving it to the hottom of the hole, then taking back and driving the hit down on a different place; the third change will clear the hole. This running with a loose chuck makes it possihle when the drill is held fast; hy driving it up and turning it with the hands on the back stroke the slight depth is gained which is needed hy the reciprocating mechanism and piston to permit their working properly. The character of the rock and the percentage of moisture present has a marked influence on the proper angle at which a hole should he pitched; the stroke length is also a factor not to be ignored, as a machine having a long stroke will pull a drill out of a hole where a short-stroked drill won't hudge. A long barrel hehind the hit likewise plays a part in keeping the drill dirt stirred up and moving toward the mouth of the hole. A dry rock of even texture may he drilled practically flat whether it cuts coarse or fine. On the other hand, a close-grained rock cutting fine cannot he drilled horizontally if a small amount of moisture is present, an amount not noticeahle in coarse cutting, granular formations. Hard sulphide ores are treacherous. Stick a drill in a hole in a fine-cutting hlack sulphide of iron or galena and it stays there until shot out. The small iron rod mentioned in the outfit for the machine is an efficient tool for loosening a choked drill unless it is packed too tight.

Where the hole varies but little from horizontal and passes from a soft rock into a very hard one at an ohtuse angle, a few pieces of hard quartz the size of hickory huts placed in the hottom of the hole will generally cause the drill to "take" in the harder rock; in water holes a track spike or two will effect the same purpose. In drilling water holes in argillaceous rocks, the mudding of a hole is frequently very annoying. This can be ohviated by cranking the machine hack, pouring in a small can of water, then turning on about a quarter of a head of air and churning the stiff mud while running the machine up.

A shrewd ohserver soon learns his stope and can greatly simplify his work by being alert to notice changes in vein structure or variations from normal in hardness, moisture, etc. The judicious use of power greatly simplifies the handling of the machine in the various contingencies arising in putting in a difficult hole. This is a feature of machine running that requires much experience and sound judgment to thoroughly master.



When the round is successfully put in the holes must he thoroughly cleaned and loaded. Here is where knowledge is valuable. An ignorant or careless man can easily waste his salary hy a profligate use of powder. For machine holes a gelatine powder should always he used, as the explosive does away with the expensive annoyance of a burned out hole. The fuse used should he the hest obtainable. The great majority of miners know how to load holes, and failures result principally from defective or badly made fuse.

In hlasting ore, when very hard, an ahundance of explosive should be used, as the rock is shattered into small lumps and a lot of lahor saved, which costs more than powder. In stopes filled with waste it is best to shoot the ore first, letting the foot wall holes go first where the waste is taken from the hanging wall. This method puts the ore in one place and greatly facilitates cleaning up.

While hreast holes are recommended for hreaking ore, uppers or half uppers drilled very deep where the rock is friahle or brittle meet the requirements for filling. It is not necessary to load waste holes heavily, the least quantity of powder that will break the hole heing sufficient.

Beaudry Champion Power Hammer.

The Beaudry power hammer, illustrated herewith, claims favor for several things, among which are elasticity and control of the blow struck by it, these heing because of a new device, simple, direct acting and effective, allowing the ram freedom of throw, and causing it to rebound the instant the hlow is struck. The operator has constant control of the force of the hlow, which may be of any degree from very light to very heavy (according to the pressure on the foot treadle), and on widely varying thicknesses of stock without change of adjustment. The ram has no reaction or jump. The hammer requires but light power. The manufacturers say that its

Beaudry Champion Power Hammer.

simple design, the unusual strength of its parts and thorough workmanship insure permanent durability.

This hammer has no beam, no saddle, no ruhher cushions or leather straps, no coil springs, nor any form of spring and link connections of numerous wearing parts. The ram or head is of steel, and has an internal curved track of ( ) shape, shown hy dotted lines in the illustration. The two spring arms, with rolls at their lower extremities, operate within the ram upon this curved track, and serve to lift and throw the ram, which, with increased speed of the hammer, acquires increased travel and force of hlow. The simple, positive action of the spring arms controls the ram, and causes it to rebound the instant the hlow is struck, without reaction or jump or sudden undue strain on any of the hammer parts. The box pillar frame is rigid, occupying small floor space, and requiring a foundation of moderate size. The anvil is an independent casting having no connection to the frame, thus preventing crystallization of the hammer parts. The crankshaft, of large diameter, runs in hard hronze hushing chambered for oil. The crank pin is adjustable for varying lengths of stroke. The connecting rod runs on a bronze sleeve. The connecting rod, spring hox, and ram are steel castings. The spring arms are forged from Swedish steel, and have hardened tool steel rolls. The tension on the spring arms is adjusted hy two tension nuts in the spring box.

The heavy ram guides are cast solid with the frame and have an adjustahle wedge-shaped gib, by which the wear, if any, can he taken up to the one-hundredth part of an inch. The ram is adjustahle for varying heights ahove the dies. The full stroke can be had on a piece 4 inches square as readily as on a piece ½ inch in thickness, and no change in adjustment is required except for unusually heavy or special work. The anvil has an independent adjustable shoe die. Full length hars can he worked either way of the dies. The ram is counterhalanced by weight in the pulley. The positive hrake will stop the hammer almost instantly, and will hold the ram at any desired position of its stroke. The hammer is direct acting. It can he made to run at the will of the operator at a high speed, and deliver hlows from one pound to its full capacity. These hammers are huilt solely hy Beaudry & Co., 147 Milk street, Boston, Mass.

Graphite in Canada.

By far the most important use of graphite is in the steel, copper and copper-alloy industries as a refractory material in making crucihles, retorts, muffles, hoxes, stirrers, etc. Other important uses are for luhricating, foundry facings, stove polish, paints, electrotyping and pencils, writes H. P. H. Brumell in the Canadian Mining Review.

The two well-defined trade divisions of this mineral are "amorphous" graphite and "crystalline" graphite. The former is usually of lower grade and suitahle for facings, paint, pipe-joint grease and stove polish, although the hetter qualities, particularly from Bavaria and Mexico, are used also in the manufacture of pencils and electrotyping, while for crucihle making, luhrication, high-grade stove polish and electrotyping, the purer or crystalline variety is generally necessary. The principal source of supply of crystalline graphite is the Island of Ceylon, from whence the ore is shipped in its crude form, after heing sorted and sized, the grades heing "lump," "chip," "dust" and "sweepings." The first two sizes form the hulk of the output used by crucihle makers, while the "dust" and the "sweepings" are utilized for lubrication stock.

Amorphous graphite is found principally in Nova Scotia and New Brunswick, where it occurs as graphitic shale and clay. The most important deposits are those in the vicinity of St. John, N. B., others of lesser note occurring in Kings and Westmoreland counties, N. B., and at Lochaher, N. S. In Ontario several deposits of amorphous graphite have been found in Halihurton and Hastings counties, while in Brougham township, Renfrew Co., an extensive deposit occurs, having associated with it a considerahle proportion of flake or crystalline graphite. This property is heing operated hy the Ontario Graphite Co., which has lately installed a plant, and is now refining and shipping the product.

The largest known deposits of crystalline graphite are in the counties of Ottawa and Argenteuil, Quehec. Smaller deposits occur in Lanark, Leeds and Frontenac counties, Ontario. Of this quality there are two distinct classes of ore, "lump" and "disseminated," the former usually occurring in limestone, as nodules, or filling pockets and small veins. There are also many minor occurrences where the lump ore constitutes small veins in diorite or other igneous rocks. As yet no discovery of lump has warranted systematic mining. Disseminated graphite is practically a sillimanite or other gneiss carrying graphite in a flaky or crystalline form, and varying in graphite content from a trace to 35%. These bands of gneiss are found in the townships of Buckingham and Lochaher, Ottawa county, many heds having a thickness of over 20 feet, and assaying on an average ahout 20% graphite. A numher of heds have heen opened and ore extracted and treated at the different mills in the district.

The process of manufacture adopted hy the different producers has heen jealously guarded, the "secrets" being considered the individual property of the refiner. Irrespective of secret methods, the practice adopted may be divided into wet and dry processes. No mill confining its operations to the dry or air method has as yet heen commercially successful, hecause the similar gravity of the component minerals prevents a satisfactory separation. Several pneumatic separators lately put on the market have heen partially successful, although they have not been ahle to eliminate the mica.

The wet or water separation method has been successful and high-grade graphite is heing produced in this manner hy the North American Graphite Co. of Buckingham, which is, at present, the only company in operation in the Province of Quehec. It is expected that the plant of the Walker Mining Co. will soon he at work. In the process of concentration used by these companies the ore is crushed and stamped wet, and a coarse separation made by stationary huddles. The concentrates are then dried, ground hy buhrstones and screened. An improve-

ment, resulting in a saving in cost of about 25%, has lately been made by the use of the Brumell separator, which treats the ore after drying by flotation upon, rather than immersion beneath, the surface of the water. By the wet method a higher degree of concentration is obtained than by the dry process, and the ground and finished concentrates retain their size of particles. As a consequence, those companies which employ wet methods are enabled to put upon the market the largest sized and purest flake crucible and lubricating stock.

Analyses of picked samples of graphite made by the Geological Survey of Canada have shown the following results:

Locality.	Carbon, Per Cent.
Buckingham township, Quebec (foliated)	99.675
Buckingham township, Quebec (columnar)	97.626
Grenville township, Quebec (foliated)	99.815
Grenville township, Quebec (columnar)	99.757
Ticonderoga, N. Y. (foliated)	99.656
Ticonderoga, N. Y. (columnar)	97.422
Ceylon (foliated)	99.679
Ceylon (columnar)	99.792

Dredging and Valuing Dredging Ground in Oroville, Cal.*

NUMBER II.—CONCLUDED

Written by NEWTON BOOTH KNOX.

CALCULATING THE AVERAGE VALUE PER CUBIC YARD.—The value of each hole in cents per cubic yard is multiplied by its depth in feet, and the sum of the products divided by the sum of the depth. The quotient is the average value in cents per cubic yard. Thus we have a block of dredging ground drilled with one hole to every 10 acres.

The sum of the products obtained by multiplying each depth by its corresponding value = 14.046. The sum of the depths is 660 feet. Dividing the first by the second gives 21.28 cents per cubic yard = average value of this ground. The average depth is 33 feet, or 11 yards.

FINAL CALCULATIONS.—At an average of 11 yards deep this ground will contain 53,240 cubic yards to the acre, and allowing 3240 cubic yards for ridges and "corners" left in dredging, we have 50,000 cubic yards per acre, or 10,000,000 cubic yards in the 200-acre tract under consideration. This at 21.28 cents per cubic yard gives a total content of $2,218,000.

Assuming the price is $150,000, cost of a 5-foot bucket dredger $65,000, working capital $10,000, the total cost is $225,000.

A 5-foot bucket dredger is rated at treating 65,000 to 70,000 cubic yards per month, but up to the present time the best these dredgers have been able to do has been about 70% of the possible running time. It may be added that the new dredgers now building hope to better this, and will doubtless bring up the running time to 80%. In fact, a new dredger, the Butte, which has been running but three months, has during that time averaged 75%, and the last month of their run they have averaged 86% of the time. Assuming 70% running time, a 5-foot dredger will work out this ground at the rate of an acre per month, or, in all, about seventeen years for the tract. Assuming a working expense of the dredger as high as $3500 per month, or $42,000 per year, and that 1 cent per cubic yard is left in the tailings, we have:

Total value in ground	$2,218,000
Total value in tailings	100,000
To be recovered	$2,118,000
Total cost of treatment	714,000
Net gain in ground	$1,314,000
Net annual gain for seventeen years	77,300
Net annual gain, 34 3%, or, allowing a sinking fund—seventeen years' life, annual contribution to sinking fund—to be at 3%	10,300
To be applied to dividends	$ 67,000
Gain per cent per year on investment, with sinking fund	30

COST OF DRILLINGS.—The running expenses of a driller per day is:

Labor—One driller		$ 3 50
One fireman		2 50
One teamster and team		3 50
Chinese rockerman		1 50
Total for labor		$11 00
Wood, half cord, at $6		3 00
Repairs, say		5 00
Drill hire		5 00
Total expenses per day		$24 00

Drilling about 10 feet a day gives a cost of $2 40 a foot. Drilling contracts at Oroville are let for $2.50 per foot, and considering delays, breakdowns, repairs, road cutting and moving from hole to hole, this figure is reasonable enough. The number of feet drilled per day varies greatly, and depends on the character of ground and the season. In soft ground 20 feet to 30 feet a day can be drilled, with a corresponding reduction in cost per foot. In winter and spring, when the top soil is wet and soft, the problem of moving the machine from hole to hole, and of bringing wood and water, becomes a serious one. Just to show the extra difficulties, delays and stoppages a driller must contend with, I quote in full the log of Mr. Radford for December, 1902:

1st—Started hole No. 12, but did not do much owing to lack of good driving cap and scarcity of water. Made 14 feet.

2nd—Drilling on hole No. 12 all day. Made 7 feet.

3rd—Started about 7:30 A. M. Broke sand pump about 8:15. Had to take it to town and get it repaired. Finished hole No. 12 at noon. Commenced pulling casing 12:30. Finished and moved to hole No. 18—1320 feet. Set up and started drilling.

4th—Worked all day on hole No. 18. Made 20 feet.

5th—Wet; did not work.

6th—Started work on No. 18 after lunch. Made 7 feet.

7th—Wet; did not work.

8th—Worked on hole No. 18. Made 11 feet. Started pulling up casing.

9th—Finished pulling up casing from hole No. 18; moved to hole No. 20—about 900 feet. Ground very soft; had to raise drilling machine with jackscrews and to keep it up by means of wood placed under the wheels. Made 14 feet in hole No. 20.

10th—Wet; did not work.

11th—Wet; did not work.

12th—Worked on hole No. 20.

13th—Finished hole No. 20—34 feet deep. Pulled up casing and started moving to hole No. 14; ground very soft.

14th—Moved to hole No. 14 and set up machine. Ground very bad in places. Distances from No. 20 to No. 14, 1320 feet.

15th—Working on hole No. 14. Made 17½ feet.

16th—Working on hole No. 14. Reached depth of 28 feet. Broke bolt in driving blocks. Got new one from machine shop in town. Lost two hours.

17th—Finished hole No. 14—29½ feet deep. Pulled up casing and moved machine a short distance towards hole No. 16.

18th—Moved machine about 100 yards. Got into soft mud and stayed there all day.

19th—Raised machine out of the mud. Took off gear ring on account of broken teeth, and took it into town and got it repaired.

20th—Got gear ring about noon, put it back on machine and started; ran short distance towards hole No. 16.

21st—Moving machine to hole No. 16. Road very bad in places.

22nd—Moving to hole No. 16—1320 feet from hole No. 14. Set up machine and started drilling. Struck old drifted ground. Made 21 feet.

23rd—Finished hole No. 16—29 feet deep. Pulled up casing and moved toward hole No. 10.

24th—Finished moving to hole No. 10—1320 feet. Set up machine and drilled 4 feet.

25th—Worked on hole No. 10. Reached depth of 19½ feet.

26th—Wet; did not work.

27th—Ground too soft to haul wood and water.

28th—Working on hole No. 10; reached depth of 31 feet.

29th—Working on hole No. 10; reached depth of 41 feet. Stopped.

30th—Finished pulling casing from hole No. 10 soon after lunch. Started moving to hole No. 8.

31st—Finished moving to hole No. 8—1320 feet. Set up machine and started drilling. Broke walking-beam arm. Had to send to town for a new one. Lost three hours. Made 13 feet.

Although the crew worked a ten-hour shift during this month, only seven holes were finished, giving a total depth of 212.5 feet, or an average of 6.8 feet a day.

I quote this, not as an example of average work, but merely, as I have said, to show the difficulties, particularly in winter.

VALUE OF THESE TESTS.—Three years' drilling, followed by subsequent dredging of the drilled tract, has proven that these tests are but fairly indicative of the values in the tract. For instance, one company, in order to prove the efficiency of these tests, drilled an acre of ground with twenty-three drill holes, which afterwards dredged within 95% of the calculated value. On the other hand, I have heard that a company with a recently finished modern dredger has already dredged about 6 acres, which produced 35% of the drilled values—two holes to the acre. It is unfortunate that more exact data regarding the value of these tests are not at hand. Engineers will recognize the ever-present liability of error and consequent dissatisfaction arising from all work where the value of the large is calculated up from the value of the small. So the chief value of this method of testing ground lies not so much in proving the total possible yield of a piece of ground, or its values in sight, but in indicating the presence and occurrence of the pay channels, depth of bedrock, water level, etc. It is now the custom to keep a driller well in advance of the dredger, the results of the drilled holes serving as a guide for its future movements.

The accompanying engravings show modern type bucket dredgers, in construction and in operation.

Jeffrey Grab Buckets.

Few more interesting and important problems from an economical standpoint have attracted the attention and called forth the best efforts of our brightest engineers than those involved in the unloading and subsequent disposition of ore and coal from vessel to furnace or consumer, with the necessary stocking and reclaiming because of the difficulty in securing cars to handle the enormous cargoes as rapidly as they are taken from the holds. Among the devices more or less successful, the automatic grab bucket or clam shell has proven itself adapted to the work, its manufacturers say, and to such an extent is this recognized that older vessels are being altered and new ones are building, so that these buckets can take out from 95% to 98% of the entire cargo.

The Jeffrey Manufacturing Co. claims to have brought out a bucket which combines with simplicity

Jeffrey Grab Bucket.

and power, great capacity per unit of mass in motion, the weight of the moving mechanism being reduced to the minimum per unit of ore handled—a bucket whose life under the rough usage to which these devices are subjected while strenuous will prove a long and useful one.

These buckets have a remarkable spread, the one having a capacity of three tons of ore being 11 feet over all when open, while the five-ton bucket opens to 15 feet. The closing path is most efficient and in opening the load is cleanly and entirely discharged. An important feature is the small head room required. It permits reaching under the decks and keeps down height of tower. These buckets will handle ore, coal, including run of mine, bituminous sand, limestone, and may be used for dredging and excavating. These are also proving an economical means of handling coal and ashes in power plants, also for transporting coal long distances from and to the stock piles.

The Jeffrey Co., Columbus, Ohio, are prepared to furnish suggestions as to methods, also plans and estimates for installations for unloading and handling material in bulk in any quantity.

Cost of Electric Drilling.

John B. Hobson, M. E., general manager of the Consolidated Cariboo Hydraulic M. Co. at Bullion, B. C., in his annual report gives some interesting figures of costs of operating an installation of Gardner electric drills, says the Canadian Mining Review. The plant, which was an experimental one, included four Gardner No. 15 drills with 2 H. P. 110-volt direct current portable motors, one Gardner "B" drill, with 1½ H. P. 110 volt direct portable motor, all complete, with 7-foot flexible shafts, adjustable tripods, the necessary flexible cables, working tools and five sets of drills of suitable lengths to drill holes, varying from 2 to 8 feet deep. Mr. Hobson states that these drills proved a decided success, for they were run at low expense and proved more efficient than expected:

STEAM POWER.

One cord of cedar wood, delivered	$2 25	
One electric engineer	4 00	
Lubricants for engine and generator	35	
		$6 60

OPERATING THREE DRILLS.

Three power drill men at $4 each	$12 00	
Three helpers at $2 each	6 00	
One blacksmith	4 00	
One helper	2 00	
Three bushels of charcoal at 25 cents	75	
Lubricants	20	
		$24 95
Total cost of running three drills ten hours		$31 55

The duty attained by the Gardner drills used during the season, in advancing and lowering the bedrock cut, averaged 312 feet of holes per ten-hour shift.

The duty attained by two miners drilling by hand, with ⅞-inch steel and eight-pound hammers, averaged about $14\frac{5}{10}$ feet per ten-hour shift, and made

the cost of drilling 312 feet of holes in bedrock by hand as follows:

Forty-two miners at $2 per day	$84 00
One blacksmith at $4 per day	4 00
One helper at $2 per day	2 00
Four bushels of charcoal at 25 cents	1 00
Total cost of drilling 312 feet of holes by hand	$91 00
Saving made in favor of power drills per ten-hour shift	50 45

Mining in Broken Hill, New South Wales.*

Written by EDWIN K. BEAUMONT.

The impressions of a new arrival on coming to the Barrier are anything but pleasant or reassuring, for when, after spending a whole night in rattling over 300 miles of almost desert country, one seeing the line of lode, about 1½ mile in length, with its long chain of chimney stacks, poppet heads, engine houses, concentrating mills, and immense mullock and tailings

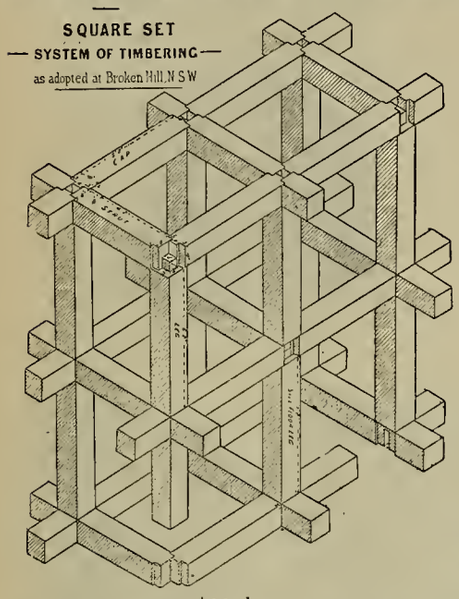


FIG. 1.

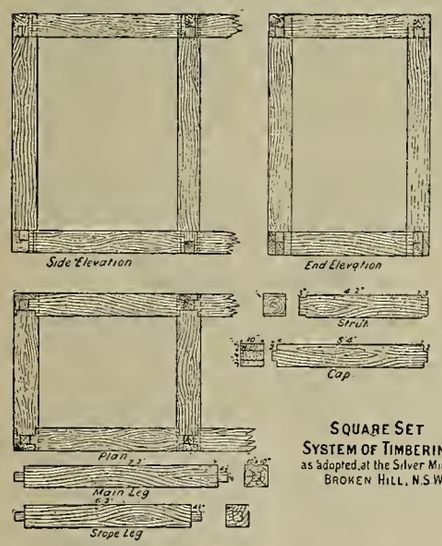

FIG. 2.

dumps, etc., finds it hard to imagine that this is the famed Barrier Range or Broken Hill, unless a mining man who has been on similar fields. The original Broken Hill is now a thing of the past, having been entirely removed by the large open cuts, from which the oxidized ore is being extracted down to about 200 to 250 feet.

EARLY MINING.—The story of the finding of silver by the stockman on Mount Gipps station and of Rasp's shaft (Rasp himself being a station hand at the time), and of the mining of earlier years, are familiar, when only the oxidized ores of the upper levels of the lode were worked down to 300 or 400 feet, and, as on new fields, the methods adopted were crude until, with great advance of output and rush of population, more modern and advanced systems were adopted; and the arrival of American mining managers and engineers with the "square set" system of timbering, as carried out in ore mines of America and elsewhere.

SQUARE SET SYSTEM.—Fig. 1 is an isometric drawing of the square set system showing sizes of timbers and all joints. Fig. 2 shows the construction in detail. All timbers are 10x10 inches, the vertical ones called legs and the horizontal ones caps and struts; they are all cut to the required size in the sawmills. Some of the mines have their own sawmills, and buy their timbers in long lengths from the Port, and cut all timbers to templates. They are sent underground ready for the miners and timbermen to frame up in the stopes. When the ore is hard and compact (and it is hard sometimes, especially in the class of ore containing rhodonite), I have frequently seen five drills blunted to bore a hole less than 1 inch; but when the ore is friable it is then timbered close up to the working face (as shown in Fig. 3) on the upper floors. You will notice that in this system the miners are always working close to the face or hack, which they can easily examine to make sure of its safety. One disadvantage of keeping the timbers so close to the face is that frequently a heavy shot will "throw," and thus knock down several sets and shake others, thereby causing delay and rendering the working face unsafe until the timbers are re-erected. You can readily imagine the difficulty in securing them all as firmly as they were originally. Lagging of 10x2-inch Oregon pine are laid on each floor as the stope rises upwards to the next level, and chutes for conveying the broken ore to the sills and thence to the trucks are provided at convenient intervals, and slides placed to run the ore to the chutes from the working face, as shown on the plan and section showing the stope (Fig. 3). It will also be noticed that the end sets of each floor are wedged firmly to the foot and hanging walls of the ore body, and frequently notches or hitches cut to secure a solid bed. In theory, as a system by itself, these seem admirable, but in practice (without being filled with waste as they now are) they fail, for after the ore has been extracted, any movement or pressure of the walls of the lode causes a collapse of the sets. They have gained the weird name of "creeps," and a more complete state of chaos can hardly be imagined than a creep, that is, broken and splintered timbers, and masses of ore and mullock in one almost unapproachable mass, often rendering the further working of that portion of the lode impossible, and thereby losing large quantities of ore in the debris; but it is a noticeable fact that in those mines where the managers did not rely on the timbers alone, but judiciously filled in the sets with mullock from wall to wall (leaving only the necessary openings for chutes, gangways, etc.), when any movement came in the walls of the lode the timbers and surrounding filling stood the burden, and the mines were singularly free from "creeps." Some idea of the pressure on these timbers may be imagined, when I state that I have seen a piece of 10x10-inch Oregon pine compressed to barely 3 inches; have also seen a 10x10-inch vertical leg driven 4½ inches into the horizontal cap and sill at its ends, without bending the leg, and have frequently noticed, when there has been any lateral pressure, the 10-inch piece of Oregon splintered like a piece of willow on the convex side, and on the concave side, though bent 1 foot, was still unbroken.

FIG. 3.

LIFE OF TIMBERS.—The life of timbers underground depends a great deal on location. In some mines I have noticed Oregon pine that had been in approximately ten years almost sound, while in others the same class of timbers, if put in a badly ventilated stope, in about three or four years had completely decayed by a kind of moldy dry rot. In the upper portions of one mine I noticed a lot of joggled logs of blue gum, from 6 inches to 9 inches diameter (brought from the river in early days), and they were worm-eaten and quite rotten, while the mulga and black oak, both hard native timbers, were quite sound; but as these latter are usually only about 4 inches to 8 inches in diameter they are almost useless for underground timbering, except as laths, or for latticing the sides of square sets and enclosing the mullock fillings, for which they are sometimes used. I omitted to mention when describing the mullock filling of the square sets that 10x2-inch planks are used by some mines, but other mines having their own sawmills, rip the 10x2-inch lath in halves and use the 5x2-inch lath, thus effecting a small saving in the amount of timber used; but I have noticed also that these lighter laths frequently give way when any great pressure from the mullock is thrown on them.

Other great detractions to the square set system are the great cost of timber and the liability to fires.

COST OF TIMBER.—When considering the amount of timber required to timber up a lode the total feet is enormous, and at, approximately, $38 per 1000 feet, the cost greatly reduces the profits. We have in the Central a width of over 270 feet from foot wall to hanging wall at the 600-foot level, the greatest width on the Barrier, taken out in blocks about 50 feet wide right across from one level to another, viz., 100 feet.

FIRES.—There is the liability to fires, of which the fire in Block 11, of about 7 years ago, and the fire in Block 12, of four years, both of which are still burning, are examples. These cause great expense in extinguishing and greatly hamper the working of the upper portions of the lode. So much timber of inflammable nature is a great menace, especially when the stopes are well ventilated by winzes from the upper workings. These winzes serve as vents or chimneys, and spread the gases throughout the mine, and the result is loss of life, as it was on both occasions referred to, when men went below to locate and attempt to overcome the fire.

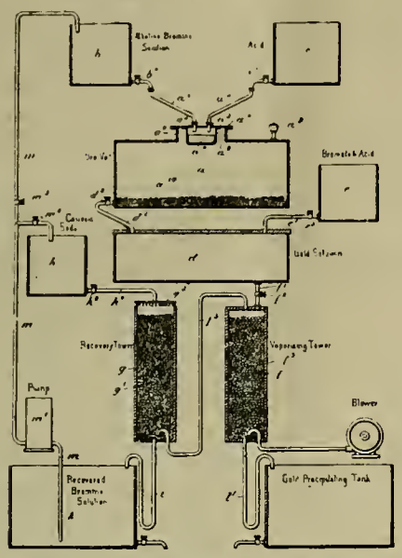
It will be seen that the deduction to be drawn is that this system is an admirable one when combined with filling; but it is also an expensive one.

LATER SYSTEMS. — Owing to the sulphide ore requiring more costly and tedious treatment and preparation before smelting than oxidized ores, and the many and varied expenses incidental to the mining, due to the hardness and the work of extraction and handling, it was necessary that managers and others interested should devise some safer and cheaper methods, which would also be more suitable to the class of ore to be mined and treated, and thus, born of actual experiment and necessity, these later methods have gradually evolved into their present forms; and their almost universal adoption on several mines on the line of lode—with sundry modification to suit individual cases—proves their efficiency. The square-set system is far from annihilated, as it is still used where applicable, especially on the sill floors where gangways are required, also chutes, outlets, etc. Here the sets are on solid bottoms; being well wedged against the hanging and foot walls or the sides of the stopes, they are firm and permanent, and with the 10x3-inch planking to carry the mullock filling they form convenient passages about the workings. So it is still used in conjunction with these later systems, as a valuable and necessary adjunct.

(TO BE CONTINUED.)

RECENTLY a French patent was issued to A. Tar and, S. Mathiea and H. Lasne for a process of utilizing burnt pyrites, in order to recover from them the cobalt and other metals which they contain. A solution is formed in the usual way, and the copper is precipitated by means of metallic iron. The iron sul-

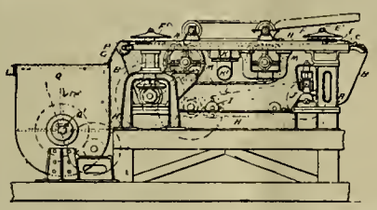
*Trans. Aus. Inst. Min. Eng. (condensed).



phate thus formed is then crystallized out and the liquor is evaporated to dryness. The residue thus obtained is calcined at a dull red heat. It is then digested with acidulated water, whereby cobalt, nickel, zinc and manganese pass into solution, together with some iron, while the residue enacted upon furnishes a salable paint. The iron is then precipitated by powdered chalk and a current of air. After that the cobalt and nickel are removed by chloride of lime, or any other oxidizing agent, and carbonate of lime, and the zinc by lime, while the manganese remains in solution.

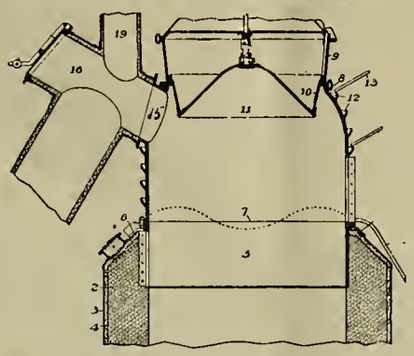
Mining and Metallurgical Patents.

PATENTS ISSUED JULY 7, 1903.



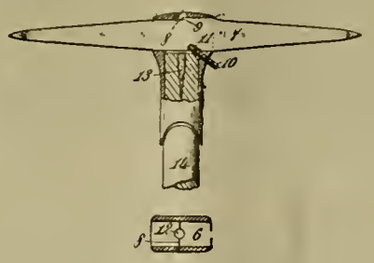
Specially Reported and Illustrated for the MINING AND SCIENTIFIC PRESS.

PROCESS OF EXTRACTING GOLD FROM ORES.—No. 732,708; H. R. Cassel, New York, N. Y.



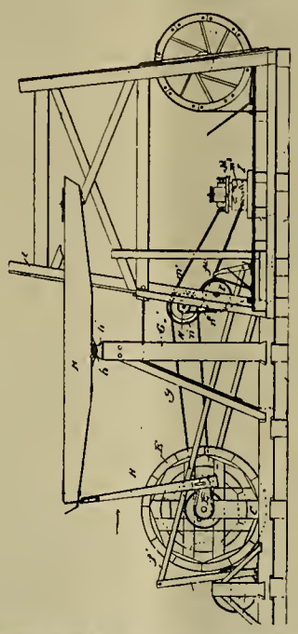
Process extracting gold from ore treating ore with bromine solution form dissolved gold and bromides, mixing bromate with acid, and causing mixture to act upon dissolved gold and bromides to set free bromine of bromides and bromate.

APPARATUS FOR SEPARATING LIQUIDS FROM SOLIDS.—No. 732,720; H. Duncan and R. R. Sherriff, Glasgow, Scotland.



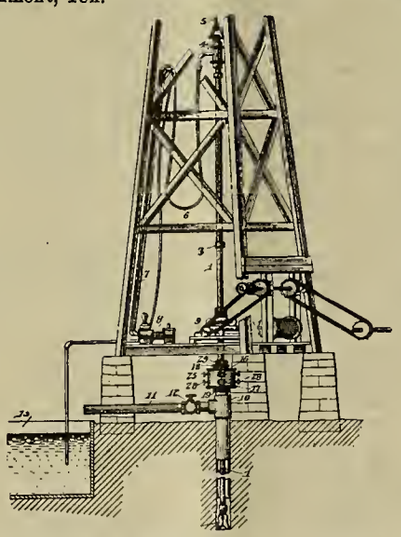
Machine for separating liquids from solids comprising framing and gear carrying and traversing endless band filter cloth, automatic clip devices securing band, vacuum box on under surface of band and interposed endless band wire cloth or gauze arranged support and travel with filter band.

BLAST FURNACE TOP.—No. 733,196; G. K. Hamfeldt, Munhall, and T. A. Tesch, Swissvale, Pa.



Blast furnace having annular metal shell projecting above masonry and having contracted upper portion, hopper supported on contracted portion, and outer annular cooling device for shell.

MINER'S PICK.—No. 733,449; A. Walker, Whatcheer, Iowa

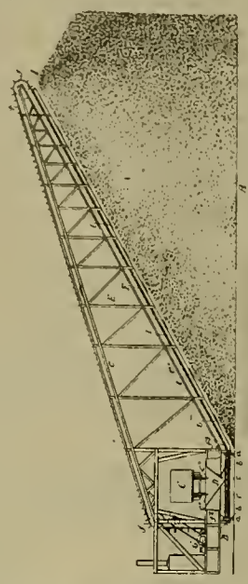


Socket having eye combined with blade removably extending through eye, provided with single shoulder centrally of its length, eye having interiorly coacting and single shoulder located centrally thereof, and means for holding shoulder of blade against that of eye.

COMBINED CABLE AND ROTARY RIG FOR DRILLING DEEP WELLS.—No. 732,785; L. C. Sands, Jr., Pittsburg, Pa.

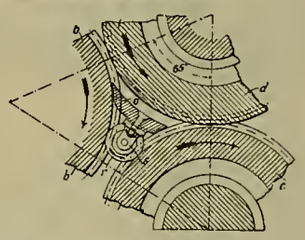
In combined cable and rotary rig for sinking wells, combination with derrick of hoisting drum, rotary table movable to and from well opening of derrick, and driving mechanism adapted to actuate rotary table, or hoisting drum.

OIL WELL DRILL.—No. 732,925; H. R. Decker, Beaumont, Tex.



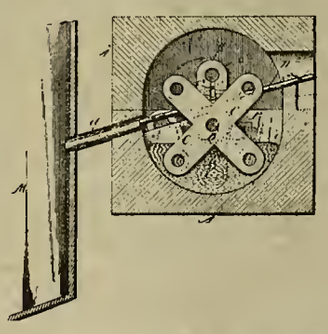
In apparatus of class described, combination with rotary drill pipe, and well casing receiving drill pipe and closed at top provided with lateral outlet, of locking device comprising stop connected with well casing, and means carried by drill pipe for engaging stop, whereby drill pipe be prevented from being blown out of well casing.

PROCESS OF LEACHING ORES.—No. 732,605; G. E. Thede, Havilah, Cal.



Process leaching ores which consists mixing with ore metallic oxide, treating mixture in cyanide solution containing oxide capable of reducing metallic oxide.

STORAGE APPARATUS.—No. 733,355; J. M. Dodge, Philadelphia, Pa.



In apparatus for piling material, movable frame, hopper carried by frame, guides on frame for means of feeding hopper, and conveyor on apparatus arranged to receive material from hopper.

THREE ROLL CRUSHING MILL.—No. 733,125; J. J. E. Bekker, Amsterdam, Netherlands.

In crushing mill, frame, plurality pressing rollers mounted to revolve in frame, interengaging grooves in rollers, returner bar in proximity to one of rollers, returner bar being provided with teeth that register with grooves of roller, and wheels on returner bar that turn in grooves of roller and in grooves of next succeeding roller.

QUICKSILVER FEED FOR AMALGAMATORS.—No. 733,301; J. W. Swearingen, Gaston, Cal.

Automatic feed for quicksilver, comprising case forming reservoir, shaft bearing rotating arms having buckets in ends, and inclined trough having spout at one end, handle at other and blade or lip adapted to be juxtaposed to arms.

THE Canadian government has decided to give a bounty of $2.70 on steel from July, 1903, to June, 1904, $2.25 to June, 1905, $1.65 to June, 1906, and $1.05 to June, 1907. Also a bounty of $6 a ton on wire rods sold to manufacturers of wire. On large steel plates now admitted at a low duty there will be a bounty of $2.70 a ton on such made in Canada. The same bounty is proposed for structural steel. On steel ingots, puddled bars and pig iron it is proposed to give the same bounty as last year, the gradual reduction which began last year being suspended for this year. Under the gradual reduction the bounty will be off in 1907. Last year the Dominion Iron & Steel Co. earned $350,000 on the bounties in force, and it is estimated with the additional bounty the company will show earnings considerably in excess of $1,000,000 on its finished product, pig iron and steel.

Mining Summary.

Specially compiled and reported for the MINING AND SCIENTIFIC PRESS.

ALASKA.

(Special Correspondence)—The influx of people, machinery, capital, etc., is beyond all expectations, and a prosperous season is assured. So far, nearly 5000 people arrived on the first fleet of boats, and all accommodations for passage were taken up. Also, about 60,000 tons of freight have reached the camp, including an outfit for a railroad from Solomon to Council, a distance of 50 miles.

On many creeks work has started, the snow having disappeared in this one hot wave we are experiencing at present. For the last ten days we have had 90° every day—weather as hot as in the year 1900.

From all indications, we should be able to produce at least $10,000,000 of gold this season, and then only a small portion of the section will be worked. The output last winter is estimated at $1,250,000, the Snowflake mine alone, on Dexter, producing $250,000.

Nome, June 24.

A strike is reported made 20 miles from Sunrise in the Cook Inlet country on Juneau creek, tributary of Six Mile creek, by L. Laurison, J. Renner and R. Michaelson, and the pay goes from 25 cents to $2 to the pan on bedrock.

ARIZONA.

COCHISE COUNTY.

The Swisshelms group of forty-four claims, in the Swisshelm mountains, has been sold to J. L. Wood and S. S. Wood of Pittsburg, Pa. A steam hoist will be put in. Assays show the ore to run well in copper.

The new pumps in the Lowell shaft of the Copper Queen mine at Bisbee are controlling the water. The shaft is being straightened preparatory to resuming sinking. It is proposed to put in two additional boilers, which will give them power for heavier hoisting work.

GILA COUNTY.

J. B. Newman has bought for $5000 a one-third interest in eight patented mining claims and a 10-stamp mill, north of Payson, in Green Valley mining district, says the Globe Silver Belt. The claims do not adjoin and they include the Oxhow, Golden Wreath, Delaware, Summit and American.

MOHAVE COUNTY.

(Special Correspondence).—The Enterprise mine in Wallapai mountains, 15 miles east of Kingman, operated by the Enterprise M. Co., W. A. Mensch superintendent, at Kingman, is sinking a shaft which is down over 300 feet on a vein of lead ore carrying thirty-seven ounces silver and values in gold. The ore is worth about $60 per ton. At the 300 level the crosscut has tapped a parallel ledge of milling ore.

J. P. Wallace, manager of the Monmouth M. & D. Co. on Burro creek, has completed 7 miles of wagon road to Peach Springs and the milling plant is being built. The gold is in a vein of soft, red oxides.

The Arnold mine at Cedar has been cleaned out and work resumed, keeping the 20-ton mill in operation.

The Penn Yan mine at Layne Springs, owned by G. W. Bowers of Kingman, is producing good gold rock. The vein and gangue matter are 2 feet wide, all being saved for shipment.

Ore shipments from Stockton hill are better than for some years past, the Earl and Treasure Hill mines shipping the largest quantities.

The Portales de Oro M. Co. are having their claims at Union Pass surveyed for patent. The ores are low grade and the company will build a concentrating mill.

Several new bodies of gold ore have recently been opened up in Cerbat district, near Stockton hill, one of them by J. Dixon, the vein averaging 10 inches of eight-ounce gold ore.

Chloride, July 13.

W. J. Tarr of Los Angeles, Cal., president of the Southwest Turquoise Co., says final payments have been made on the Mineral Park group and operations will begin this month. C. E. Sherman of Mineral Park is vice-president and superintendent. Their lapidary shop is at Los Angeles, Cal.

J. P. Wallace, general manager of the Monmouth D. Co., operating near the Burro mines, near Kingman, says arrangements will be made for the installation of a reduction plant on Burro creek. The ores are free milling.

The 40-stamp mill of the Mohawk G. M. Co., 7 miles northeast of Needles, Cal., on the other side of the Colorado river, is ready for operations. It will crush ores from the Leland-Mitchell group. The stamps will not begin dropping until the Mohave & Milltown Railway is completed, which is 17 miles in length and reaches from the company's mines to the bank of the Colorado river, opposite Needles, passing the mill midway, says the Eye. A cable ferry will be built across the river.

L. Hoffman, president and manager of the Chloride G. M. Co., operating the Samoa and 4th of March mines at Chloride, is preparing to make ore shipments by pack train, and will send out a carload per month.

SANTA CRUZ COUNTY.

The 50-ton concentrating plant of the Arizona G. & C. M. Co. is in operation. The company's mines are in Salero district of the Santa Rita mountains, but its office and smelter are at Patagonia. The ores to be treated carry copper, silver and lead values.

YAVAPAI COUNTY.

The Lucky Verde M. Co. have started work on their mine near Jerome.——Work on the Apex group, near Jerome, has been temporarily suspended pending settlement of the estate of the late J. G. McBride, who was interested in the company.

J. B. Tomlinson, superintendent of the Yeager Canyon C. Co., near Jerome, says he has machinery on the ground, including two 80 H. P. boilers and a ten-drill air compressor, which he expects to have in operation by August 1. The building for the mill is going up.

J. H. Wood of Prescott, manager of the Wood Mines Co., reports work going ahead at the Roosevelt group, owned by his company. The shaft has been enlarged and retimbered, a hoist put up and preparations made for extracting ore. At depth of 60 feet they have 20 inches of free-milling ore averaging $34 per ton. He is arranging to build a 5-stamp mill.

YUMA COUNTY.

Machinery is being put in at the Las Trigos placer fields, 10 miles northeast of Ehrenberg, by a company of New York and Chicago men, who intend to work the gold-bearing gravel by the dry process. J. E. Smith is manager.

Bullard's Cunningham Pass group in Cunningham Pass, near Yuma, has been bonded to W. H. Bates. The property consists of five claims, and two shafts have been sunk below water level at 200 feet down. Ore shipments of the first-class ore to the smelter gave 16% copper and one ounce of gold.

The G. H. Ward group, at Harrisburg, covering a peak and ridge adjoining the Socorro, has been bonded to G. W. Middleton of Prescott and work started this week.

CALIFORNIA.

AMADOR COUNTY.

W. E. Stewart says work has been started on the Butte basin gravel claim, near Jackson. It is intended to sink the shaft 40 feet deeper and prospect the gravel at that depth.

At the Sand Pile mine, near Forest Home, D. Fricot is putting up a cyanide plant to treat the accumulations of tailings from the Plymouth Con. mills. It is said assays show $2 per ton in gold.

Ore shipments are being made from the Grand Prize mine, in Pioneer district, adjoining the Horn mine, owned by G. S. Andrews.

The framework of the hoist at the Fremont Con. shaft, near Amador City, is in position and work on the mill progressing. It is expected the mill will be ready to run by September 1.

At the Kennedy mine at Jackson the cleanup for June is reported at $40,000, the product of seventy stamps.

CALAVERAS COUNTY.

At the Rooney mine, in Chili gulch, near Mokelumne Hill, they are timbering the main gangways, north and south, and finishing up the north and south stations. Grading for the 3-stamp mill is in progress. This mill will be run by electricity. The pump and mill machinery are on the ground.

Superintendent J. A. Sommers of the Woodhouse mine at West Point has closed the property down pending the putting in of heavier machinery to handle the water which is coming in.

EL DORADO COUNTY.

A tunnel is being run at the Vandalia mine, near Shingle Springs, under the old workings.

The water in the Mt. Pleasant mine at Grizzly Flat has been lowered below the 500-foot level, and they have started to run a drift south from this level.

The unwatering of the Havilah mine at Nashville is completed and operations resumed.

KERN COUNTY.

The Kern Trading & Oil Co. has been organized in New York, with J. Kruttschnitt of San Francisco, Cal., J. Wallace, W. A. Worthington, J. L. Willcutt and J. E. Foulds as directors. They have taken over the holdings of the San Joaquin Oil Co. and the Reed Crude Oil Co., both of which were controlled by the Associated Oil Co. The Associated is one of the most important independent oil companies in California. Besides the San Joaquin and Reed, the constituent companies of the Associated include the Canfield Oil Co., Green & Whittier, Wolverine Oil Co. and other smaller concerns. They own 60% of the Kern river district, near Bakersfield, and 90% of the McKittrick district—in all 200 wells. It controls 5490 acres and has a daily output of 12,500 barrels.

It is stated the stream of oil through the Standard Oil Co.'s Bakersfield-Richmond pipe line will reach Point Richmond next week and the officers of the company claim the capacity of the line will be 10,000 barrels a day. The reports of the line being a failure are denied, and it is thought it will hardly be necessary to construct more than four additional pumping stations.

MARIPOSA COUNTY.

The Exchequer M. Co. is opening up the O'Brien claims on the Merced river, near Mariposa, and has fifteen men on three shifts. A shaft is being sunk to connect with the tunnel, which is also being driven.

NEVADA COUNTY.

(Special Correspondence)—The Blue Tent G. M. Co., operating a group of gravel properties north of Nevada City, is making preparations to put up a 20-stamp gravel mill. Construction work will begin this month. C. L. Canfield is president.

On Shady creek, a 1200-foot bedrock flume has been started by the Shady Creek M. Co. They are putting in a hydraulic elevator and a mile of pipe. Full operations are expected to be under way August 1.

Nevada City, July 14.

The Centennial mine, 3½ miles from Grass Valley, will be reopened this week, says G. W. Root, manager of the Grass Valley Con. M. Co., which owns it.

The Zeihright M. Co., F. Zeitler of Nevada City, president and superintendent, has begun operations at the Zeibright mine, south of Grass Valley.

L. H. Mitchell has bonded the Wright & Bailey group, adjoining the Boss mine, 2 miles from North San Juan, and has men at work on development.

The Kentucky Ridge mine, near Grass Valley, has been sold to an Eastern company, of which A. Helsey is local manager. There are two tunnels driven, each showing a vein which contains milling ore. The lower tunnel is in 400 feet and the upper tunnel 200 feet.

PLACER COUNTY.

At the Nissen mine, being operated by A. Russell of San Francisco, men are at work making cuts and building flumes. A hydraulic plant will be put in. Russell proposes to buy the Rising Sun mine, a free milling proposition, near Colfax, says the Herald.

Near Ophir the Boulder mine is being unwatered, says Manager Ayers of San Francisco.

The International M. & S. Co. of New York has begun operations at the Southern Cross mine at Humbug canyon, near Towle. They will build a 20-stamp mill, says E. J. Trimble, superintendent.

SAN DIEGO COUNTY.

Work is progressing at the Stonewall mine, near Cuyamaca, says the Julian Miner. Their sawmill is turning out 1000 feet of lumber a day, which is being used at the mine and in improving and enlarging buildings. Manager Lucas has twenty men at work. The mine will be unwatered.

At the Owens mine, near Julian, the work of pumping out the water is progressing. It is the intention of the Phelps-Dodge Co. to sink 50 feet from the lowest level and drift 50 feet after unwatering.

SISKIYOU COUNTY.

At J. Quigley's quartz mine at French Gulch, on Indian creek, rock averaging $5 per ton is being opened up and he proposes to build a mill. The Tyrer & Co. mine at Klamath river, below Klamathon, reports work progressing and the 10-stamp mill running steadily.

TUOLUMNE COUNTY.

It is reported a partial reorganization of the Golden Gate M. & S. Co., near Sonora, will be made. It is planned to increase the capacity of the mill as to batteries, crushers and concentrators; sink the shaft 500 feet deeper, says the Banner.

J. Vincent of San Francisco has bought the Realization quartz mine, east of the Tuolumne river, near Groveland.——B. Jennings of San Jose has an option on 120 acres of gravel land on Table Mountain, near Sonora, for $5000.——J. E. Williams of Stockton has bought a half interest in the Fraction quartz mine, on Knight's creek, adjoining the Sunset mine, and B. M. Hohenshell of Stockton has bought a fourth interest in same.——P. Rowe has bought a third interest in the Bell quartz mine, near Tuttletown.

At the John Royal mine, near Columbia, stoping is going on in the east drifts at the 100-foot and 200-foot levels; five stamps are dropping in the mill and shipments of concentrates are being made, says Superintendent W. A. Holmes.

At Soulsbyville, at the Soulshy mine, operations have been resumed by W. Sharwood, part owner.

Work has been resumed at the Mack mine, near Groveland.

Superintendent Stayton of the Willieta mine, near Sonora, says a tunnel has been run in on the vein and the depth gives them about 150 feet of backs on both shoots. It is proposed to put in electric power and a concentrating plant

COLORADO.

BOULDER COUNTY.

A 2-foot vein of shipping ore has been opened up in the Copper Glance mine, near Ward, one of the mines of Sunset district, says Superintendent W. J. Barrett. Shipments are being made to the smelter.

The Blue Grass M. Co., operating at Phœnix, is taking out high-grade ore and have started building a mill to handle their own ores.

The Boulder & Denver Water Power Co. has been organized, having bought the Barker property near Nederland, and will build an electric power plant and mill for treating low-grade ores. The directors are W. S. Boynton, F. R. Jeffery, R. W. Norrington, A. Remley and A. C. Patton. W. S. Boynton of Colorado Springs is president. The company proposes not only to deliver power for a mill it intends to erect on Four-mile, but for sale of it for mining, smelting, manufacturing and other purposes.

W. Capp of Denver, manager of the Eagle Rock M. Co., operating on Boulder creek, 9 miles west of Boulder, says near the Cochrane mill he is driving a crosscut tunnel in Sugar Loaf mountain. The Milan mine is on the course of the tunnel. The first of the company veins to be cut is the Independence, then the Post Boy. The tunnel is in 800 feet and they have 50 feet to drive to cut the Independence, which has a shaft 214 feet deep, and showing $20 ore.

CLEAR CREEK COUNTY.

T. M. Fisher of Colorado Springs reports making final payment on the New Year mine, 1 mile from Idaho Springs, on the Virginia canyon road. It has been developed by a shaft 120 feet in depth and the drifts extended. Some lead ore has been opened up.

The Gold Medal group, near Idaho Springs, resumed operations last week with S. B. Swink as superintendent.

J. A. Wright of Denver, manager of the Lucania tunnel, near Idaho Springs, says their operating plant was started up this week. They have put in a 14x16 compressor to operate five drills. Their boiler capacity is 100 H. P.

Work on the Vidler tunnel of the Transcontinental Co., near Georgetown, is going ahead. The grading for the compressor plant was started last week and the road started to connect with the county road. The road to the sawmill site is finished and the machinery is being taken in.

W. S. Liehrick, manager of the Little Mattie M. & M. Co. of Colorado Springs, operating near Idaho Springs, says developments are progressing in the fourth and fifth levels. In the former workings Lessee Parker is developing a shoot yielding high-grade ore for a distance of 250 feet, and he has 100 feet in depth on it, being between the 300 and 400-foot levels. The company is driving the fifth level. It is proposed to put in a 50-ton cyaniding plant, which will be increased to 100 tons later. The mill is running full time. The jig concentrates are running $118 a ton and $55 a ton from the tables. It is reported the Little Mattie will construct an aerial tramway from the mine to their mill, which is on Chicago creek. This would save a haul of 1 mile.

CUSTER COUNTY.

It is reported that a company is being organized at Pueblo to develop the Clara claim at Rosita. This claim is near the Humboldt mine. The shaft of the Clara mine is down 40 feet and ore samples show silver, lead and gold values. Machinery is on the ground and the shaft will be continued down 100 feet more and stopes carried toward the Humboldt vein.

DENVER COUNTY.

(Special Correspondence).—It was the intention of the union to place pickets at each of the plants of the American S. &

R. Co. and to boycott the smelter should the company attempt to open up with non-union men. The trust has secured an injunction against the Federation from boycotting, picketing or interfering in any way with the smelters or its employes. The Globe plant is resuming under police protection. The Grant plant will remain closed indefinitely. No serious trouble is anticipated. At the Standard mill at Colorado City the men have gone out, but it is thought the trouble will not extend as far as at first supposed.

Denver, July 13.

DOLORES COUNTY.

The concentrating plant at the Group tunnel, near Rico, is expected to be in operation before Aug. 1, says Superintendent C. D. Hooper.

GILPIN COUNTY.

J. R. Anderson of Pittsburg, Pa., president of the Pittsburg Con. M., M. & T. Co., says they have bought the Gold Dirt mines at Perigo. He states there are 3000 feet of the west end of the property that is practically undeveloped. A new cage shaft will be sunk on the vein, and as the lode is nearly vertical it will be started 200 feet above Gamble gulch. A concentrating and stamp mill of 100 tons daily capacity will be built between the shaft and the gulch. A good wagon road connects the mines and mill with Rollinsville, 1½ mile. The Pittsburg Co. also owns the Dover and Brighton mines in Idaho Springs and Freeland districts, in Clear Creek county, says the Post. W. H. Knowles of Denver is manager.

GUNNISON COUNTY.

The Moro mill of twenty tons capacity is being remodeled hy J. M. Gardner of Pittsburg. Pa. The mill is near the mouth of Jones gulch, 4 miles above Ohio City. It is intended to increase the capacity, says the Times.

On Cinnamon and Baldy mountains on Crystal river, near Elko, H. C. Clark of Leadville, manager of the Gregor G. M., L. & M. Co., says they are doing development work. Another tunnel has been started 200 feet below the previous workings. Their ore carries gold, silver, copper, lead and zinc.

D. C. Tohin & Co. are operating the Erie & Eureka-Nest Egg group, near White Pine, under lease. These lie under the David H. and join the Akron holding. The Akron Co. have started work of remodeling the concentrating mill for treating concentrating ores from neighboring mines, as well as their own. Another property in operation is the Alwilda group of ten claims on Granite mountain, and owned by Fuller & Riley, who are working them. A tunnel has been driven 850 feet, with 200 feet of drifting, showing 1½ foot of concentrating ore between walls of granite that runs 12% lead, 12 ounces silver and $2 in gold per ton, says the Times.

The East Rock M. & M. Co. resumed operations last week on the Hercules and Ajax mines, near Elko, says Manager S. E. Day. The principal work to be done at present will be development. A vein has been opened, 3 feet wide, running $2 in gold, 20 ounces silver and 4% copper.

LAKE COUNTY.

The Republic S. & R. Co. will build a duplicate of the Salida plant in Leadville, work to begin this month, says Manager Goodwin. For the present two lead furnaces will be installed, with a capacity of 200 tons each, and a matting furnace later, but it is expected to add two more. The completed plant will have a capacity of 1000 tons a day.

LA PLATA COUNTY.

The Neglected mine, near La Plata, is shipping high-grade ore to the Durango smelter and will ship concentrates also from the mill. Seventy-five men are employed.

MINERAL COUNTY.

(Special Correspondence). — Mining around Creede is improving. On the list of shippers are the Big Kanawha, Delmonte, New York and Chance, Commodore and Bachelor mines. The Bachelor is being operated hy lessees. The camp is shipping 6000 tons per month. The Corsair and Alpha each ship 15 tons daily. The East Willow M. Co. is operating the Solomon, Ethel and Moses. They have a concentrating mill which handles 60 tons daily. They are putting in more tables and jigs.——The Humphrey mill is handling 5000 tons of ore per month from the United Mines and making 45 tons of concentrates per day. The mill has been operated by water power, but they are adding a steam plant to furnish power for winter operating. They have plenty of water this summer. L. H. Norton is superintendent and J. D. Hawkins manager.

Creede, July 13.

RIO GRANDE COUNTY.

(Special Correspondence)—The Kansas City Tunnel Site M. Co., 6 miles east of Jasper, have their tunnel in 800 feet. They intend building a reduction plant. L. K. Kramer, Monte Vista, is manager. The ore carries gold, silver, lead, copper and zinc.

Jasper, July 12.

SAN JUAN COUNTY.

A 14-inch pipe line is being built to supply water power for the Highland Mary mine and mill near Silverton. The line will be ½ mile in length with a 950-foot fall.

G. Howard is reopening the Creole Belle mine, near the Sunnyside mine, near Silverton.

M. Heiser of Eureka has resumed work on the Montezuma (Tucson) mine in South Eureka gulch, near Eureka.

The Dewoy claim in Horseshoe basin, on the edge of Burrows Park, near Silverton, has eleven men at work. Shipments will be started next week.

The tramway line extending from the American tunnel to the Gold King mill at Gladstone is being overhauled to the extent of placing a new stationary cable of 1½-inch size and the attachment of additional buckets to increase the transportation of ores to 200 tons daily capacity, says the Silverton Standard.

SUMMIT COUNTY.

The French Gulch Placer Co., near Breckenridge, is using five giants. In order to double the output of gold, a dredge will be built, which they expect to have floated before the present season is over, says the Journal.

At Argentine, the Rothschild Co. has driven its tunnel into Cooper mountain a distance of 2400 feet. Heavier machinery will be put in, including an air compressor capable of driving eight drills.

The Uthoff mine, at Kokomo, is being worked again, says Manager Uthoff, the owner.

TELLER COUNTY.

Operations are resumed on the Mayhelle group, on Lawrence town site, below Victor, and it is intended to continue sinking to 500 feet. An air compressor, electrically driven, will be used to furnish the power.

According to estimates made by the surveyors, the Cripple Creek drainage tunnel will be completed by August 15, says S. Aldrich, chairman of the Cripple Creek drainage committee. The tunnel was driven 665 feet in June, being at the rate of 22½ feet a day; only four headings were worked, as a good flow of water is being developed in the fifth, northeast of the shaft. There remained 1032 feet to he run July 1. It is now seen the tunnel will unwater the Cripple Creek basin, as the northeast breast is getting a flow of 300 gallons a minute; so that further work in that heading is unsafe until the tunnel is opened to that portal.

President K. Macdermid of the C. K. & N. Co. says that as soon as the Cripple Creek drainage tunnel is completed to the El Paso shaft and unwaters that area, Lessee Granfield & Co. will run a crosscut from the shaft at 550 feet to connect with the El Paso workings. This crosscut will constitute a lateral of the drainage tunnel and will serve as an outlet from the C. K. & N. mine, as Granfield proposes to put a pump in the bottom of his shaft and lift the water to the crosscut, whence it will flow out of the tunnel. This will be but a short lift for the water.

The Isabella directors at Colorado Springs have given a three years' lease to T. Murphy and C. C. Hamlin for the entire holdings of 100 acres near Cripple Creek.

The Ajax G. M. Co, operating on Battle mountain, near Cripple Creek, are preparing to set up a heavier pump on the 1100-foot level.

The Kimball Investment Co. of Denver has bought of the Legal M. & M. Co. the Saturday lode claim on Rosebud hill and the Colnage lode claim on Tenderfoot hill, Cripple Creek.

The payrolls of Cripple Creek district for month of June were distributed last week to a total of 6286 men, and aggregated $654,778. The leasing of the Stratton estate mines and the completion of the drainage tunnel will cause still further increases in the number of men needed in and about the mines.

The mines on Bull hill, Cripple Creek, owned by the Empire State Con. G. M. Co., have been taken over by W. H. Spurgeon, H. C. Cassidy, et al. Included in the claims held by the Empire State Co. were those formerly owned by the Arrow G. M. Co. and Orphan G. M. Co.

The Merrimac Leasing Co, operating the Merrimac mine, near Cripple Creek, are putting in a steam plant of machinery. They will sink the shaft another 100 feet.

The El Paso Co. at Cripple Creek has granted a lease on the dump of the old shaft to D. Bernard, who has put in a steam washer and has started work washing the rock. The washing machine will treat 100 tons of rock per day.

The executors of the Stratton estate have granted several additional leases on their ground at Cripple Creek including: J. A. Himebaugh of Colorado Springs on the Geneva; A. J. Francis of Cripple Creek on the Monitor; G. Johnson and J. Lund on the Geneva; C. Lund and A. Nelson on the Nada. The property on which Himebaugh has a lease has a shaft 600 feet in depth.

A three-drill compressor has been set up on the Climax No. 1 and a crosscut from the tunnel of the Climax No. 2 will be driven by H. P. Wilkins et al. of Boston, Mass., who have a lease on the ground from the Little Puck Co., which is on Squaw mountain, near Cripple Creek. The crosscut is expected to cut the Ocean Wave vein.

Manager T. Cornish of Stratton's Independence at Cripple Creek says a cyanide plant is being built.

The Independence Con. Co. at Cripple Creek resumed work last week on company account above the first level (300 feet in depth). The company will work in the two veins that were opened up in crosscutting. One vein contains smelting grade, while the other is of milling ore Pumps will be put in on the 1250-foot level and the shaft will be sunk an additional 100 feet. Additional boiler capacity is to be installed. This work will be independent of the work being done by the Cripple Creek M. Co., which has a lease from the first level down to depth of 1250 feet. W. P. Dunham is manager.

Oastler, Tomlinson & Pender Bros. have built a cyanide plant to work the Ingham dump, owned by the Doctor-Jack Pot Co. at Cripple Creek. It is estimated in the dump there are 5000 tons, assaying $4 in gold. A crusher, a pair of rolls and four tanks are in place. The cyanide plant at the Van Fleet sampler, near Goldfields, is reported doing satisfactory work. All the ore for this mill comes from the Ironclad claim that is under lease to Rice & Temple.

The Gold King claim, near Cripple Creek, of the Savage G. & C. M. Co. of Colorado Springs has been leased to H. S. Rankin for two years at graded royalties. He will develop through the Good Will tunnel, which cuts the property between 500 and 600 feet.

IDAHO.

BLAINE COUNTY.

The Rosetta District D. Co. has been incorporated at Hailey hy C. C. Ruthrauff, C. Hernsheim and J. H. Miller of New York to operate in Rosetta district on the Little Smoky river, 35 miles from Hailey.

The Rosetta M. Co. has been incorporated hy C. C. Ruthrauff and B. F. Jackson of New York City, G. D. B. Hasbrouck of Kingston, N. Y., and L. Thompson of Westfield, N. J., to operate in the same district.

The Little Smoky M. Co. has also been organized hy the same parties.

BOISE COUNTY.

R. L. Hordern, working a group of claims at the head of Little Bull Dog creek, 2 miles west of Pen Basin road and 16 miles from Alpha, reports opening up free gold ore assaying $20. The ledges are 3 feet wide between a granite and a porphyry contact.

CUSTER COUNTY.

Manager Czizek of the Lost Packer mine in Loon Creek district, near Custer, says it is proposed to build a mill this summer. Work will begin this month.

IDAHO COUNTY.

R. S. Law reports making second payment on the Kimberly and Jewell groups of claims in Marshall Lake district, which is under bond to Law, Hill & Co. of New York City for $65,000. A Chilian mill of 40-ton capacity will be put up this summer and will be run by water power. There is a 160-foot tunnel in on the Jewell and an exploration shaft and some tunneling on the Kimberly. They propose to build a wagon road from Goff, a station on the stage road, to Lewiston, 40 miles from the Meadows.

F. S. Myers, part owner of the Silver King mine at Warren, has sixteen miners at work at the Silver King and the Keystone mines, having resumed last week. An engine and hoist have been placed on the Keystone. The ore will be taken to the Silver King mill. It is the intention of the Silver King M. Co. to increase development work.

OWYHEE COUNTY.

Additional equipments are being put in hy the McKinnon G. M. Co., near Silver City, and Superintendent McKinnon has started the crosscut tunnel to open their group of claims.

A motor and blower were put in at the Addie mine tunnel, near Silver City, last week. Stoping has begun.

SHOSHONE COUNTY.

The St. Louis & Idaho M. & M. Co. has been incorporated to develop three claims on Canyon creek, between the Hercules and the Tiger-Poorman mines, near Burke. Galena, carrying 25% lead and some silver, is shown in the croppings. A 300-foot tunnel is being run. R. F. Collins of Wallace, D. D. Barbee of St. Louis, Mo, G. D. Collins of Jerico, Mo, and I. S. Collins of Lewiston are incorporators.

The Tiger-Poorman mine resumed operations last week after being closed down since May 19, when the hoist and crusher buildings were destroyed by fire. These have been rebuilt.

The Springfield M. Co., operating near Mullan, is shipping ore to the smelter, which assays 16% copper and $5 in gold.

KANSAS.

CHAUTAUQUA COUNTY.

R. R. Pitkin, A. E. Stilwell, J. C. Richardson and T. Morgan of Joplin, Mo., are prospecting a number of gas and oil leases near Niotaze on which they have two drill rigs in operation. They report having a large flow of gas in one drill hole, which is down 900 feet. The other drill hole is down 400 feet.

MONTGOMERY COUNTY.

J. M. Parker of Independence reports the Bank's well completed and flowing. The opening of this well shows the presence of oil under the Walker mound where the well is located. One-half mile east of this well is the Fellows' well, which produces twenty barrels daily.

MICHIGAN.

HOUGHTON COUNTY.

The Lake Superior concentrating works on the Franklin sands, near Hancock, resumed operations last week, after a long shutdown because of the explosion which wrecked the cylinder of the engine.

At the Rhode Island mine, near Calumet, they are sinking winzes below the eighth level at a depth of 1000 feet. On that level the crosscut is being driven west and has opened up a good lode. The winze is sinking from a point on this drift 25 feet south of the crosscut.

The St. Mary's Mineral Land Co., near Winona, is diamond drilling for the lode operated at the Winona mine.

KEWEENAW COUNTY.

Near Allouez the company has men at work on the Miswabik property test pitting east and west from a common starting point. Test pits 4x5 are being sunk 8 feet. The overburden is light. The Kearsarge lode has not yet been struck.

ONTONAGON COUNTY.

The mill of the Mass Con. C. Co. of Mass City in June stamped 8469 tons of rock, producing eighty-eight tons of mineral. The remainder of the month's product of 172 tons was eighty-four tons of mass copper. The management has adopted the filling system in use at the Baltic mine and hoisting of waste rock will in future be avoided. By September they expect to send 500 tons of rock daily to the mill.

MISSOURI.

JASPER COUNTY.

An increase of $391,432 is shown in the value of the output of the zinc and lead ores of Joplin district for the first six months of 1903 over the same period of 1902. This gain was made, too, with a decrease of 13,662 tons in the zinc shipment and 1576 tons of lead shipment. The average price of zinc was $34 per ton, against an average for the same period of 1902 of $28 48. The average price of lead was $54.30, against $43, says the Joplin News-Herald.

The Rex M & S. Co., near Joplin, are doing considerable prospecting. They have a lease on 400 acres of land east of the original 1000-acre tract, and have two drills prospecting. The pumps are at work on the mines that were recently flooded.

The Florence G. M. Co. has been incorporated at Joplin by J. D Bowersock, H. L. Moore, H. S. Clarke, I. Hill of Lawrence, Kan., A. G. Cummings, B. T. Love, N. H. Wright, J. H. Legg of Joplin.

The Barr None M. Co., operating on the Modoc lease south of Joplin, has put in a boiler and engine and a steam hoist. A drift has been started and they are taking out pay dirt.

At Carterville the Missouri Blanket Vein M. Co. has sold its mill and all its machinery and has quit mining, says the Carterville Record.

F. Nicholson of Joplin has bought a prospect on the Eleventh Hour lease for $30,000. The property consists of four lots on the Eleventh Hour ground with a shaft down showing a 20-foot face of ore, says the News-Herald.

LAWRENCE COUNTY.

At Stotts City the Keystone mine has its mill in full operation and the mine has been unwatered.

The Mt. Vernon M. Co., which has a lease on 200 acres of mining land in Stotts

Clty dlstrlct, is preparing to sub-lease on tracts of five acres.

NEWTON COUNTY.

The pumpling machinery at the Buckham mlne at Granby is in operation.

STONE COUNTY.

At Baxter sprlngs it is reported that a mlli will be built at the Sunny Slde mine and work will be started this month.

At the Tom Clark mine drifting has begun on the lead ore. The ore in the bin is lump ore only, as the fine dirt has not been cleaned.

MONTANA.

CHOTEAU COUNTY.

J. Torgenson, superintendent of the Mission Peak M. Co., operating near Landusky, says their 10-stamp mill is running steadlly. Tbe ore averages $7 per ton in gold. He proposes putting in a cyanide plant. They ship some high grade ore.

FERGUS COUNTY.

The pay rolls of the Gold Reef Co., at Glit Edge, show sixty men on the works, says tbe Argus. Of these, twenty men are prospectlng in the mlnes, and others are working on the construction of the roasters. It is expected the roasters will be put in operation August 1st.

FLATHEAD COUNTY.

The Snowshoe mine, near Libby, has begun shipments of ore and concentrates. The concentrator is running full time.

J. H. Geiger, manager of tbe Illinois & Montana M. Co., says work will be resumed on thelr group in West Fisher dlstrlct, near Libby, and that, in addition to development tbis summer, the company will build a mill.

It is reported that work at the Banner & Bangle mine, 6 miles south of Troy, operated by Larson & Greenougb, under a bond, is progressing and shipments of ore will be started this month, says the Western News. They have decided to bulid a concentrator at the mine.

JEFFERSON COUNTY.

Machlnery is being put in at the Evening Star mlne, in Cataract district, near Basln.

Muivahill & Ely, lessees of the Daly group at Wlckes, are making shipments to smelters of their first-class ores, and have enlarged their concentrator to 100 tons per day capacity. Tbey have started slnklng 200 feet from the 600 level.

LEWIS AND CLARKE COUNTY.

The Mlssouri & Montana Co., owning the Sure Thing mine in Ontario district, near Helena, is increasing development work. Canol & Martin of Helena, the principal holders, expect to place a smelter on the group this summer.

The Lee Mountaln M. Co., operating at Rlmini, has increased its shipments since the completion of tbe three-rail gravity tramway from tbe mine to tbe railroad. The mine hss been shipping 800 tons of ore a month to the smelters and concentrator, which will be increased to 2000 tons.——J. Kuykendall of Helena bas leased the Tathem group of claims ln Rimini district.

It is reported the Montana Co., Ltd., has taken a lease and bond on the property of the Cruse Mountain Con. M. Co. and also the South Drum Lummon M. Co., near Marysvllie, says the Mountaineer, and operations are to be begun this week.

MADISON COUNTY.

(Speclal Correspondence).—The three dredgers near Virginia Clty are operating with great success tbis summer. The one operated by the Chicago M. & D. Co., W. W. Parker superintendent, will cease operations next fall, upon expiration of time lease from Conroy Placer M. Co.

Virginia Clty, July 13.

The Kearsarge mine, near Virginia Clty, started last week to sink a three-compartment shaft for 500 feet; the only stop to be made is at the 130 foot level, where a station will be cut to connect the new shaft with the present workings, says the Inter-Mountain.

Manager Godfrey of the Montana & St. Paul M. Co., operating near Twin Bridges, says operations have begun on their claims on Wisconsin creek at Old Baldy mountain. They have uncovered three shoots of shipping ore.

POWELL COUNTY.

Manager G. J. Kirby of the Montana United M. Co. has bought the Elroy, the Poorman and the Hemlock mining claims, near Emery. These claims are north of the Emery mine, and the first two adjoin tbe Sunday.

NEVADA.

ELKO COUNTY.

G. E. Gavin of Boise, Idaho, developing the Riddie mine, near Elko, reports tbe tunnel being driven ahead. The mine has a 20-stamp mill which is run by electric power. The Bull Run is opened up, and has a 10-stamp mill.

LINCOLN COUNTY.

The Ione M. Co. is preparing to start development work on tbe Pompeii, American Girl and Independence - Golden Garter groups, near Searchlight, which it has under bond. These are north of the Blossom group, being operated by tbe Southern Nevada Co. F. J. Spare is manager, and he will put in an air compressor and two macbine drills. Two shafts will be sunk.

WHITE PINE COUNTY.

A group of fourteen claims north of and adjoining the New York & Nevada C. Co., near Ely, bave been taken under a three months' bond by W. C. Rose for Eastern men.

NEW MEXICO.

GRANT COUNTY.

Near Bromide, tbe Strawberry mine, which has been idle for several months, resumed work last week with eleven men, says Superintendent R. Cole. Work will consist for the present of sinking the sbaft and crosscutting at the 100-foot level. The Strawberry has steam machinery and air drills.——Work on the Continental has been delayed for the past six weeks because of water in the shaft. ——At the Sardine mine work will be resumed, says Superintendent Roberts.——Work will be begun on the property of the Cunningham Guich M. Co. this month. The company owns several claims near the War Eagle, Continental and Tampa mines, says the New Mexican.

LINCOLN COUNTY.

(Speclal Correspondence).—The plant of the American Placer Co. at Jlcarilla will soon be ready for operation again. The machinery is all on the ground. It is about a year now since the company first attempted to operate these placers, and when tbeir dredger equipment resulted unsatisfactorily, it looked as if they would have to abandon the project. But they have had their plant remodeled and expect to handle 400 yards of dirt a day, yielding an average of $125 gold per day. Fifteen men will be required to run the whole plant, or five men per sbift of eight hours. H. L. Payne of Cleveland, Ohio, is engineer in charge of the work.

Jacarilla, July 14.

OREGON.

BAKER COUNTY.

The Gold Hill quartz mine of the Burnt River G. M. Co., near Baker City, bas been sold to C. H. McNicholas of Portland for $200,000.

J. Michaels of Minneapolis, Minn., president of the Turnagain Arm M. Co., operating in Cracker Creek district, near Sumpter, says that at the Cracker Jack, one of their group, they are preparing to put up a sinking plant with capacity of 500 feet depth. A shaft will be sunk on the Snowflake claim and tunnelling done on the Uneeda. Work on the concentrating plant at the California is going ahead and it is expected the mill will be running by August 1.

Work has been started on the Martha Washington group of five claims, in Cable Cove district, near Sumpter, by C. Warren, F. W. Northup and T. C. Gray, owners.

Work was started last week on the mines of the Cracker-Highland G. M. Co., in Cracker Creek district, near Sumpter. The company has been reorganized and H. Cummings, W. G. Perkins, J. C. Davies and A. P. Goss elected as officers, with C. H. Fenner of Sumpter consulting engineer. Tbe group is on the Minneapolis ledge. They will continue the tunnel on tbe ledge to tap the ore shoot uncovered on the Minneapolis and also sink a 200-foot shaft.

GRANT COUNTY.

Near Alamo, F. A. Wheeler, G. A. and R. E. Hills of Chicago, Ill., F. H. Hills of Northeast, Pa., H. W. Maxwell and G. H. Bowers have bought the Democrat and Earl claims, adjoining the Red Boy mine, and the Helenora M. Co. organized for development of the group. The same parties bought the Bryan mine and the Colorado & Oregon group, adjoining the St. Anthony group, near Alamo. This was for the St. Anthony Co., in which tbey are interested, and gives a total of twenty-four claims between the Alamo mine and the Black Jack and Oregon Monarch.

The Don Juan and Quebec mines, in the Greenhorn and Alamo districts, respectively, are reported sold to T. W. Davidson and A. B. Browne of Sumpter. The Don Juan is equipped with a 10-stamp mill and concentrating tables. Development consists of a tunnel on the vein and a shaft sunk 200 feet below this tunnel. The Quebec mine is near Alamo, near the south end of Quebec mountain.

There are twenty men at work at the Dixie Meadows mine, says H. P. Belknap of Sumpter, part owner. Tbe lower level is in 750 feet, but most of the work is in the upper levels. Preparations are being made to build a mill. The Dixie Meadows mine is 12 miles north of Prairie City and is on a tributary of the Middle Fork of the John Day river.

J. W. Larkin and D. R. Evans of Spokane, Wash., principal owners of tbe Cougar mine, near Granite, report operations resuming. The Cougar is equipped with a 250-ton a day dry crushing and cyaniding plant.

JOSEPHINE COUNTY.

At the Greenback mine, on Grave creek, at Greenback, Superintendent C. W. Thompson says work is progressing. The machinery for the 100-ton cyanide plant is in place and ten more stamps are being added to the mill, making a total of forty stamps. The ledges of the Greenback mine lie in Browning mountain and three drifts have been cut through the hill. The old mill, with its ten stamps, sits on one side of the mountain and the new mill, with thirty stamps, is 450 feet lower and on the opposite side of the mountain. The cyanide plant is near the 30-stamp mill. The new equipment is below the ninth level of the mine. The mine is electric lighted throughout and there are 7500 feet of tunnels, drifts and upraises, says the Ashland Record.

Tbe Golconda quartz mine, near Provolt, under development by D. J. Lawton et al., has a double shift at work, drifting on a 6-foot vein at a depth of 200 feet. The ore carries free gold and sulphurets.

At the Lucky Cuss mine, near Murphy, owned by Schrimpf Bros., Superintendent W. T. Cope reports work going ahead.

SOUTH DAKOTA.

LAWRENCE COUNTY.

The Columbus Con. G. M. Co. has an option on the Mueller-Hanley water right on False Bottom creek, near Lead, for $5000. It is intended to raise the water and convey it down Blacktail guich. Another find of ore has been made on the ground of the Columbus Con., north of the main shaft. It is free milling. The Columbus is continuing its westerly crosscut from the drift on the 200-foot level. Tbis crosscut has passed through 247 feet of ore. The vein passed through is the Pierce vein. The crosscut is being run for the purpose of cutting the Erin vein, which lies west of the Pierce.

The Echo G. M. Co., operating on False-bottom creek, ½ mile above Maitland, have done several hundred feet of tunnelling. The next work will be driving a working tunnel into the side of Echo hill. Values in gold and silver are obtained. It is intended to drive the tunnel to tap the slate porphyry contact at 400 feet below the surface.

PENNINGTON COUNTY.

Superintendent J. B. Safford of the Golden Slipper mine, near Hill Clty, says bis company will build a cyanide annex to the stamp mill, which is working on Slipper ore. Work will begin on the plant this month.

UTAH.

BEAVER COUNTY.

The Lincoln mine (the Rollins), near Minersville, was sold at sheriff's sale last week for $58,747 to F. Frour, of Lincoln, Logan county, Ill.

IRON COUNTY.

It is reported work will be resumed on the Venus mine, near the Johnny mine, at Stateline. The Venus carries gold ore.

JUAB COUNTY.

Of the seventy-five men employed at the Mammotb mine of the Mammoth M. Co., at Mammoth, sixty were discharged on the 12th inst., says the News, partly due to a disagreement between the company and the smelters. The fifteen men retained will keep the mine open.

PIUTE COUNTY.

The Mount Baldy M., M. & Water Power Co., of Marysvale, has been incorporated, with J. Patten, president; R. De Witt, vice-president, and C. P. Barnson, secretary and treasurer.

Superintendent A. D. McLean of the Madsen M. & M. Co., operating on Gold mountain, near Kimberley, says the Trapper's Pride is being reopened and development work started.

SALT LAKE COUNTY.

The Mono mill in Dry canyon, near Bingham, is in operation again, says President G. A. Land, the plant having had an overhauling.

SUMMIT COUNTY.

Manager W. I. Snyder of the California M. Co. mine and mill, near Park City, says the zinc tailings are to be concentrated for their zinc values. On the dump there are 2000 tons of these tailings, which will yield $10 per ton. The concentrator was started last week and will also treat some crude ore. The shaft being sunk to tbe 500-foot level is down 270 feet.

The Majestic M. Co. has incorporated to operate at Park City, a group of twelve claims in the eastern part of the camp and southwest of the Liberty group. C. S. Rolpb, J. and J. Nelson, F. Aubrey, E. Ryan, M. Ferguson, J. McDonald and J. Powell.

TOOELE COUNTY.

Manager Bothwell of the Sacramento mine, at Mercur, says tbey are retorting 3000 pounds of ore, deriving 450 pounds of quicksilver daily. The ore also carries gold. The ore body shows an average width of 7 feet. Tbeir gold ores also show the presence of quicksilver.

UTAH COUNTY.

The Murray M. Co. of Salt Lake Clty has been incorporated with N. Treweek, J. H. Moyle and W. H. Irvine as officers. The company owns eight lode claims in American Fork and Snake Creek mining districts.

WASATCH COUNTY.

The Ontario-Ingersol M. Co. of Salt Lake City has been incorporated to operate in Blue Ledge mining district, M. Cullen president. T. Jordan and J. Moritz are officers.

WASHINGTON.

FERRY COUNTY.

Tbe Commissioner of the General Land Office at Washington has affirmed a decision of Register Ludden of the Spokane Land Office to the effect that the Republic M. & I. Co. is entitled to tbe Wake Up Joe, Joe Dandy, Wasp, Josie, Trail and Big Bug claims at Republic. When the company applied for its patent on the claims, P. McPherson et al. filed a protest on the ground that the land was not mineral in character, says the Spokesman-Review.

Tbe Golden Eagle M. Co has started a shaft on the Peacemaker Fraction claim, near Republic, with two compartments. Manager M. R. Staight intends to sink this sbaft 500 feet, at which depth it is expected to strike the extension southward of tbe Quilp veln. The Golden Eagle Co. has two claims, the Peacemaker Fraction and Eureka Fraction, which adjoin the Quilp on the south.

The Belcher M. Co. is preparing to build a fifty-ton smelter on Lambert creek, near Republic, for the treatment of Belcher and Hawkeye ores, says the News-Miner. The first furnace put in will be designed as a unit of a 250-ton plant, to be completed later. Belcher ore carries a high percentage of sulphur and the Hawkeye ore contains sufficient silica to flux the ore of both mines mixed.

W. L. Curry says he has resumed work on the Crown Point and Summit group in Empire camp, near Republic.

OKANOGAN COUNTY.

S. E. Barron, president of the Q S. M. Co., near Conconully, says operations have begun on the Q. S. mine and they are driving an upper tunnel, which is in 840 feet.

STEVENS COUNTY.

W. S. Rogers of Spokane of the Lawrence M. Co., says they are developing a group of iron mines, near Valley, adjoining the group owned by the Hill interests. More men are to be put on.

WYOMING.

CARBON COUNTY.

Work is again under way at the Doane-Rambler copper mine, near Battle Lake, says Consulting Engineer R. G. Legg. Shipments of ore will be resumed. J. L. Powell is superintendent. The mine has fifty men at work.

FOREIGN.

AUSTRALIA.

QUEENSLAND.

Manager A. Gibb of the Mount Perry Copper Co., near Bundaberg, says the company's new furnace is in operation, with the result that 50% more ore than formerly is being treated. The total quantity of ore smelted per month is 1100 tons. The present bottom levels of the mines are showing up well. It is proposed to connect tbe George's workings at the 700-foot levels with the Kennedy mine, and thereafter all work will be carried on from tbe latter. On their outlying properties, the New Moonta and Great Freehold mines, work is progressing.

Dredging for tin in Santhorpe district during May and the first half of June was retarded both by drouth conditions and the difficulty of providing appliances for effectively saving the tin, says the Government Journal. There is at present an ample supply of water, and in one case at least the other drawback has been overcome. Tbe Border Post says the Wylie creek dredger is running steadily and there is every indication the dredger will be able to save a good percentage of the tin. So far it has been working in clay and is making its way into the main water course. One feature of the dredger is the revolving screen, which takes off all of

the large stones, nothing passing throu h but the fine sand, from which it is easy to extract the tin in the sluice box.

From January 1 to June 15 the Mungana M. Co. at Chillagoe has sent 3582 tons of ore to the smelters, which was treated for a return of 255.0 tons of copper and 18,749 ounces silver.

The Great Northern Freehold Tin Co. at Herberton reports having struck tin at the 700-foot level.

WEST AUSTRALIA.

The W. A. Journal says, at Kalgoorlie heavy additions are to be made to the surface plants of several of the Golden Mile properties. At the Golden Horseshoe a belt conveyor is being put in to carry the mill residues on to one of the Golden Treasure blocks, owned by the Horseshoe Co. The Ivanhoe management is sponding £40,000 in extra rock drill, electric light and hoisting machinery, while the Associated Co., in addition to electric light and sulphide mill alterations, propose to build a 20-head battery for the treatment of their deposits of low-grade ore.

The experimental plant at the Lake View Consols mine at Kalgoorlie to determine the capabilities of the Elmore oil process is in operation. The plant in its present form is capable of treating fifty tons daily, and is run by electricity. At the 1200-foot level the lode struck in the crosscut driven west of the main drive, 600 feet north of the shaft, has proved to be 30 feet in width. Only the western side of the body is payable. The main drive has been turned westward at point 800 feet north of the shaft. On the 1400-foot level they have cut a lode in the diagonal crosscut west from the main shaft, width 290 feet, assay value 15 dwts. per ton, which is thought to be the Perseverance lode.

TASMANIA.

A provisional agreement for the amalgamation of the Mount Lyell M. Co. and North Mount Lyell M. Co. at Mount Lyell has been signed and a new company will be organized in London.

BRITISH COLUMBIA.

The Cariboo Gold Fields Co., operating near Barkerville, has suspended operations. —— The Consolidated Cariboo is making extensive preparations to sink a shaft on Lightning creek, 2 miles below Stanley.

The Perry Creek M. & Hydraulic Co., near Fort Steele, are building a ditch and flume 3½ miles in length. A syphon 1200 feet in length has been built across a ravine 175 feet deep. The sawmill is cutting 10,000 feet of lumber daily. Thirty men are at work, and several teams are excavating the ditch. —— Development work has been resumed on the Roaring King group of claims at the head of Perry creek, with F. Williams as superintendent.

It is reported work will be resumed on the Badger and Red Mountain group of claims, near Fort Steele. It is a free-gold proposition under bond to an Eastern company. A 10-stamp mill will be put in, says the Fort Steele Prospector.

The Kootenay Perry Creek M. Co., near Fort Steele, are sinking a shaft to bedrock to test their ground. Manager A. Banks says he will put in a stacker and washer. Operations with the steam dredge have ceased temporarily pending their arrival.

The strike at the Extension coal mines has been settled, and work begun. The proposal made by owner, James Dunsmuir, in answer to the request of the miners, was finally accepted, says the Rossland Miner. The conditions are practically the same as those in force at the time the mine closed. Dunsmuir expects to have at least 500 men working by next week. Any further increase in the number of miners will depend on demand for coal. It is thought the settlement at Ladysmith will lead to an adjustment of the troubles at Cumberland also. A Nanaimo report says the decision was hastened by the fact that a number of Chinese had been put in No. 1 mine.

Development work has been started on the Crackshot group of four claims on Macdonald creek, near Ferguson, by the owners, J. B. Manross and G. Peterson, says the Eagle.——S. Shannon, local manager for the Black Warrior M. Syndicate, says work is again under way on their group near Ferguson. M. B. Webber of Winona, Minn., is managing director.

At Nanaimo preparations are being made to unwater the Harewood mine, which has been closed down since the New Vancouver Coal Co. ceased operations there last year. President Howard of the Western Fuel Co. says when the old company stopped work faults had been reached, which were near bore holes which indicated coal. They propose to drive through the faults to the coal.

The Crow's Nest Pass Coal Co. is increasing coke shipments to the smelters in the Boundary district, thus relieving the fuel situation. A. I. Goodell, manager of the Boundary Falls smelter, says he is running two stacks and will build a third. The Granby smelter is also increasing its furnaces near Greenwood. The Mother Lode mine is working 75 men at its mine and 100 in the smelter; the Sunset has 20 men in the mine and 80 in the smelter: in the Providence 40 men are at work, 15 in the Elkhorn, 40 in the B. C. mine and 12 in the Oro Denoro.

Hydraulic mining is in full operation in Cariboo district, of which Barkerville is the center, says the News-Advertisor. The Cariboo Gold Fields, Ltd., is running two shifts, the bucket machinery being in operation. Superintendent Bailey reports progress with the boring machine at the Eleven of England.

Customs returns, says the News-Advertiser, are stated to show that as a result of the Vancouver Island colliery troubles, 13,733 tons of coal, worth $62,657, have been imported from Japan.

W. Blakmore of Montreal, consulting engineer, has started development on coal lands of the British Columbia Coal Co. on the north fork of the Kettle river, 60 miles north of Grand Forks. As soon as he completes preliminary work, including the opening up of the 5-foot seam on the Wiseman claim, a diamond drill plant will be set up.

The No. 7 M. Co., Ltd., owning a group of claims near Greenwood, will further develop the No. 7 mine and build a concentrating plant. The group includes the No. 7 mine and five adjoining claims. On the No. 7 a shaft has been sunk 320 feet, from which drifts and crosscuts have been run. The ore is quartz, carrying gold, silver, lead and zinc. The mine is equipped with a 5-drill compressor and hoist. F. Keffer is manager.

Near Rossland the Gold Hill mine, adjoining the Jumbo on the north, and under bond to J. S. Bedier, is being reopened.

The Badger and Red Mountain groups of claims on Perry creek near Fort Steele have been given under option to F. Byron, of Frank, Alberta. The properties are the Badger, Red Mountain, Perry Creek and Custer mineral claims. There are 300 feet of tunnels and drifts. The ledge has average width of 6 feet; assay returns of $20 in gold.

CANADA.

ONTARIO.

Consul M. J. Burke, writing from St. Thomas, says the bureau of mines of the Ontario Government gives the output of metalliferous mines and works of Ontario for the first three months of 1903, as follows:

Product.	Quantity.	Value.
Gold ore treated, tons....	9,688	.....
Gold product, ounces.....	2,692	$ 45,218
Nickel copper ore raised, tons.....	52,866	.....
Ore smelted, tons.....	47,880	.....
Nickel in matte product, tons.....	1,059	567,211
Copper in matte product, tons.....	780	112,676
Copper ore raised, tons.	9,940	.....
Concentrates produced, tons.....	236	10,388
Iron ore raised, tons.....	78,789	116,620
Ontario ore smelted, tons.	7,392	.....
Foreign ore smelted, tons.	18,349	.....
Pig iron produced, tons..	14,357	165,656
Steel produced, tons.....	1,340	29,480
Arsenic produced, lbs....	216,000	6,264

As compared with the first three months of 1902, the total value of production shows a decrease from $1,256,685 to $1,043,513. This is chiefly accounted for by the falling off in the output of pig iron from $397,838 to $165,656, due to shutting down at the furnaces for repairs. Nickel rose in quantity from 1485 tons to 1659 tons, and in value from $546,356 to $567,211.——The Canadian Corundum Co., which has been treating twenty tons of rock daily at its plant at Craigmont, South Renfrew, is preparing to increase its capacity to 200 tons daily. They have seventy-five men at work. Extensions are also proposed at the Belmont gold mine in Hastings. The water-power plant of 1000 H. P. will be increased, the sorting plant—large enough for 120 stamps—will be set up and the hoisting capacity increased. At present they have thirty stamps and the power is conveyed 2½ miles by means of compressed air.——The importance of the fuel question has led the bureau of mines to take a special interest in peat, lignite and other kinds of fuel found in Ontario.

GERMANY.

Consul-General O. J. Hughes, writing from Coburg, says it appears from a report in the Berg und Huettenmaennische Zeitung, the northern boundary of the Rhenish-Westphalian coal fields is being pushed forward from year to year. One company proposes pushing its derricks eastward toward Oelde. During the past three years thirty bore holes have been sunk outside the worked area on both sides of the Lippe and have all struck the carboniferous layers, mostly at considerable depth. The deepest bore holes in the Lippe region are near Schermbeck (2999 feet), Spellen (3035 feet), Huemxe (3077 feet), and Beckum (3320 feet). Several concessions have been secured in this part and five of these have started sinking shafts. All the bore holes sunk near Metz have proved the presence of anthracite coal. The Banay boring was completed at depth of 1542 feet in the coal formation; the Ravilie boring, 2369 feet depth, went deep into the coal formation; and the boring at Lerquigny went to 2231 feet, the coal stratum having been struck at the same depth as in the others. The carboniferous stratum dips under the younger formations in the direction of France and confirms a hypothesis that the Sarbruck coal measures extend toward Pont-a-Mousson. On the frontier it occurs deeper than 2297 feet from the surface.

MEXICO.

MEXICO.

The Bossie M. Co. has been organized to operate mines at El Oro and Tlalpujahua by R. Hilman, H. Bloom, P. Requena, H. Scherer Jr., J. B. McManus and R. H. Drennan. The company owns the Bessie claim of 80 pertenencias in the Tlalpujahua and El Oro mineral belt, being near Tlalpujahua. Machinery for development work is being put up. They will sink a main shaft. The Bessie adjoins the Aldibaran and San Patricio minesa nd is near the Reforma.

SONORA.

There are at least eight mills and smelters in course of erection in the State of Sonora, says the Chihuahua Enterprise. The Sonora Development Co. of Kansas City, Mo., is building a 10-stamp mill in Moctezuma district; the Yaqui S. & R. Co., composed of Toledo, O., men, a smelter at Toledo, on the Yaqui river; the Zehuite, near Tonis, a 40-stamp mill; the Reina de Oro M. Co., at El Tivo, in Altar district, has started its 5-ton Huntington mill.

PERU.

The Caylloma silver mines report the May production at 18,250 ounces fine silver in export ores and 17,000 ounces fine silver in bullion.

RUSSIA.

At Riga the imports of coal, which were mainly from England and Westphalia and which two years ago aggregated 33,000,000 poods (532,500 tons), have decreased by 193,546 tons. By order of the Government, coal is now derived exclusively from Russian mines. The local works and factories require 483,871 tons of coal and 8065 tons of coke per annum. Petroleum residuals are expensive in Riga and are only used experimentally on some locomotives on local lines. Wood fuel is also unable to compete with coal, but is used on the small branch lines. Peat, although its deposits cover hundreds of square miles near Riga, finds no application whatever because of its being comparatively expensive and inconvenient to handle, says O. J. Hughes, Consul-General at Coburg, Germany.

SPAIN.

The Pena Copper Mines, Ltd., operating at Pena near Huelva, in Andalusia province, report output of ore during May at 15,844 tons; shipments of ore, 14,788 tons; precipitate containing 61 tons of fine copper was produced. Their annual report shows 92,057 tons of ore shipped during 1902, made up of cupriferous ore, 19,927 tons; washed ore, 62,982 tons; and crude sulphur ore, 9148 tons. The chief exports of ore in the future will consist of washed ore and also some crude sulphur ore.

Commercial Paragraphs.

THE Risdon Iron Works of San Francisco, Cal., report they are preparing for shipment to Nevada Co., Cal., a 20-stamp gravel mill and accessories for the Blue Tent G. M. Co.

THE Ohmen Engine Works of San Francisco, Cal., have issued an illustrated circular of their vertical, high-speed, self-contained, center-crank engine. The illustrations show the open frame type, direct connected to electric generators.

THE Mine & Smelter Supply Co. of Denver, Colo., have shipped a Dimmick classifier and Wilfley tables to the El Cubo M. & M. Co., Guanajuato, Mexico. They received an order for two 500 H. P. De Remer water wheels and pipe line for the Rock Creek Power Co., Baker City, Or., and a 10-stamp concentrating mill for the Alamo Con. M. Co. of Spokane, Wash., the mill to be erected at Alamo, Or.

PERSONAL.

F. S. HARRIS is examining mines in Sonora, Mexico.

EMERSON GEE of Los Angeles, Cal., is in Denver, Colo.

R. COLE is superintendent of the Strawberry mine, near Bromide, N. M.

W. A. BATEMAN, of Michigan, is examining mines near Bisbee, Arizona.

R. W. HOLLIS has returned to Silverton, Colo., from a business trip to Denver, Colo.

C. NEWMAN, of Durango, Colo., has returned from a business trip to Denver, Colo.

S. B. SWINK is superintendent of the Gold Medal mine, near Idaho Springs, Colo.

J. H. KINKEAD, of Virginia City, Nev., is in San Francisco, Cal., on mining business.

E. S. KELLEY, interested in mines near Tonopah, Nev., is in San Francisco, Cal., on business.

J. W. ADAMS of Chattanooga, Tenn., is at Durango, Colo., looking after his mining interests.

A. HELSEY, of South Carolina, is manager of the Kentucky Ridge mine, near Grass Valley, Cal.

G. E. GAVIN returned to Boise, Idaho, last week from examining mining interests in Elko county, Nev.

E. GODBE, metallurgist, returned to Salt Lake City, Utah, last week from Mojave, Kern county, Cal.

J. T. TERRY, superintendent Sunnyside mines, Eureka, Colo., has returned there from Denver, Colo.

R. F. TURNBULL is superintendent of the mines of the Gold Reef M. Co. at Gilt Edge, Fergus county, Mont.

L. H. CARVER, E. M., of San Francisco, Cal., has gone to Sierra and Plumas counties, Cal., on mining business.

A. D. MCDONALD is superintendent of the Madsen M. & M. Co., operating near Kimberly, Piute county, Utah.

W. J. NELSON, interested in mines near San Andreas, Calaveras county, Cal., is in San Francisco, Cal., on business.

J. H. WARD of Bristol, Conn., is in Durango, Colo., looking after his mining interests in the Oro Fino district.

W. A. WHEELAND of Kansas City, Mo., is spending some time in Colorado looking after his mining interests.

D. BUCKLES is acting superintendent of the Mary McKinney M. Co. at Cripple Creek, Colo., vice G. Keener, resigned.

JNO. W. NESMITH, president of the Colorado Iron Works Co., has returned to Denver, Colo., from San Francisco, Cal.

J. L. POWELL, of Salt Lake City, Utah, is superintendent of the Doane-Rambler mine, near Battle Lake, Wyo.

P. M. COLLINS has resigned as superintendent of the Portland mill of the Portland G. M. Co., near Crippie Creek, Colo.

H. Z. OSBORNE of Los Angeles, Cal., is at the Dorleska mine, in Trinity county, Cal., of which he is president and manager.

E. H. LUNKEN, president of the Lunkenheimer Co., Cincinnati, Ohio, has returned to Denver, Colo., from Cincinnati, Ohio.

F. E. WILSON, of the Friday mines and mill, near Baker City, Or., has returned from a business trip to Salt Lake City, Utah.

WM. SHARWOOD, part owner of the Soulshy mine at Soulsbyville, Tuolumne county, Cal., has returned from a business trip East.

F. ZEITLER of Nevada City, Cal., is president and superintendent of the Zeilbright M. Co., operating near Grass Valley, Cal.

E. H. LUNKEN of Denver, Colo., has returned there from La Plata City, Colo., where he was inspecting his mining interests.

V. B. SHERROD, who has been examining the Bolanitos mine at Guanajuato, Mex., returned to Salt Lake City, Utah, last week.

MANAGER A BANKS of the Kootenay-Perry Creek M. Co. has returned to Fort

Steele, B. C., from a business trip to Montreal, Quebec.

ROSS E. BROWNE, E. M., of San Francisco, Cal., has been appointed a trustee of the California State Mining Bureau.

S. W. TRAYLOR, New York representative of the Colorado Iron Works Co., has returned there from a visit to Nevada and California.

G. R. LEHMAN has resigned as smelter superintendent of the Fernando M. Co., at San Fernando, Durango, Mexico, and is in Berkeley, Cal.

R. G. LEGG, of Salt Lake City, Utab, has gone to Wyoming as consulting engineer for the Doane-Rambler mine, near Battle Lake, Wyo.

W. H. TAYLOR is manager of the Republic Con. G. M. & M. Co. of Boston, Mass., operating near Dumont, Colo., vice F. H. Collins, resigned.

F. H. COLLINS has resigned as treasurer and manager of the Republic Con. G. M. & M. Co. of Boston, Mass., operating near Dumont, Colo.

C. D. HOOPER, former mill superintendent of the Liberty Bell at Pandora, Colo., is superintendent of the Group mill near Rico, Dolores Co., Colo.

B. F. GRAHAM, of Bisbee, Ariz, president of the Lucky Tiger Co. and of the Bisbee Queen Dev. Co., is in Kansas City, Mo., on mining business.

W. G. SCOTT, formerly superintendent Queen Bess mine, near Sandon, B. C., is now superintendent of the Continental-Alta mines, Alta, Utah.

S. E. PHELPS, secretary and treasurer of the Gold Coin M. Co, returned to Grand Encampment, Wyo., last week, from Idaho City, Idaho.

W. WESTON, M. E., of Denver, Colo., is in Grand county, Colo., looking after the mining interests of the Denver, Northwestern & Pacific Railway.

S. E. BARRON, president of the Q S. G. M. & S. Co., returned to Conconully, Okanogan county, Wash., last week from a business trip to Chicago, Ill.

A. A. ROSS, superintendent of the Southern Nevada mine at Searchlight, Lincoln county, Nev., returned last week from a visit to Placeritas, Ariz.

L. G. EAKINS, superintendent of the Philadelphia plant of the American S. & R. Co., has been promoted to be assistant general manager, with headquarters in Denver, Colo.

T. A. MOSMAN, who has been superintendent of the Eilers plant of the American S. & R. Co., has been changed to their plant at Leadville, Colo., and G. A. Marsh is superintendent of the Eilers plant.

H. H. NICHOLSON of Denver, Colo., has gone to Breckenridge, Summit county, Colo., to inspect working of placer operations there. From there he goes to the gold districts of Oregon in the interest of Eastern investors.

W. F. POPE of East Machias, Me., was in Silverton, Colo., last week, accompanied by F. Gifford, F. J. Robinson, A. Smith, G. Pierce, G. Boynton, W. S. Brown, E. Bunker, J. W. Dorlan, F. Johnson, E. Bruster, C. C. Chalfant, J. F. Shafer, also of Maine, and J. J. Muenger of Pittsburg, Pa., who are interested in mining in the San Juan.

Obituary.

C. BOGAN, a pioneer miner of Colorado and California, died July 8 at San Rafael, Cal. Deceased was a native of County Tyrone, Ireland, and 74 years of age. He is survived by a wife and daughter.

A. F. STOCKMAN, a student from the Minnesota State University mining school, was killed in a cave-in on the 370-foot level below tunnel No. 3 of the Bully Hill C. M. & S. Co., Shasta Co., Cal., July 7th. Deceased was 22 years of age.

M. L. DAWSON of Lynchburg, Va., assistant superintendent of the Minas Prietas mines in Sonora, Mexico, was murdered by Mexicans while on a prospecting trip near Acampo, Chihuahua, Mexico, about July 1. Robbery was the motive. Two of the three Mexicans have been captured.

DANA HARMON, mining engineer and author, died at his home in Oakland, Cal., July 9, from heart failure, after an illness of but a few hours. Mr. Harmon was born in New Orleans, La., in 1849, and went to California in 1854. After completing his education in an Eastern college he returned to California and engaged in mining, and made a success of his chosen profession. He was a keen judge of a mine and an equally good judge of men. He was a close observer of all that passed before him, and in his practical work as a miner and mine manager he was always a student, and he turned to useful account the knowledge gained by his personal experience. He was an experimenter and an investigator, and while no department of mining was strange or unfamiliar to him, he gave particular attention to the milling of gold ores, and he has left behind him as an evidence of his genius and his thoroughly practical methods, his splendid contributions to metallurgical science, the "Stamp Milling and Amalgamation of Free Gold Ores." He had a wide circle of acquaintance within and without the mining world, and his loss will be severely felt by all who knew him. Mr. Harmon leaves a widow and four children.

Our Middle West Business Manager.

On the 15th inst. Mr. Lester A. Greene assumed charge of the business interests of this journal as special Middle West representative, with offices at 1115 Monadnock Building, Chicago, Ill. Mr. Greene's business acquaintance and personality commend him favorably to present and prospective patrons.

New Patents.

DEWEY, STRONG & CO.'S SCIENTIFIC PRESS PATENT AGENCY, 330 Market St., S. F., has official reports of the following U. S. patents issued to Pacific coast inventors:

FOR WEEK ENDING JULY 7, 1903.

732,915.—TRANSMITTER GUARD—S. J. Ballard, Los Angeles, Cal.

732,818.—MOTOR—W. Ballerstedt, Los Angeles, Cal.

732,916.—WOOD CUTTING MACHINE—A. A. Bartlett, Eureka, Cal.

732,825.—TRUCK—E. J. Bryan, Riverside Cal.

733,001.—SHOE FASTENING—G. Bryant, S. F.

733,138.—PIPE WRENCH—F. D. Bullard, Los Angeles, Cal.

733,007.—LOG HAULING ATTACHMENT—S. H. Chase, San Jose, Cal.

733,009.—WINDMILL—J. Coates, Hemet, Cal.

732,831.—DISTILLING APPARATUS—J. M. Coffman, Montalvo, Cal.

732,736.—CHAIR—A. Gruenwald, Salem, Or.

733,193.—SPEED MECHANISM—R. B. Hain, Los Angeles, Cal.

733,198.—PNEUMATIC TIRE—R. A. Harris, Tucson, Ariz.

733,323.—SCREEN—E. Hipolito, Los Angeles, Cal.

733,041.—DOOR HANGER—G. W. Holly, Palo Alto, Cal.

733,208.—GATE LATCH—J. J. Hynding, Ferndale, Cal.

732,863.—BLACKBOARD—F. D. Jones, Los Angeles, Cal.

733,324.—MATTRESS STUFFER—A. R. Kezer, Los Angeles, Cal.

733,338.—ELEVATOR—D. R. Macpherson, S. F.

733,239.—TACKLE BLOCK—T. E. Maddux, Goldhar, Wash.

733,060.—WALNUT HULLER—G. F. Maiers, Goleta, Cal.

733,065.—PIPE JOINT—J. C. Martin, Jr., S. F.

733,074.—STAMP AFFIXER—W. E. Newton, Oakland, Cal.

733,361.—KEYBOARD—G. L. Noe, Wieland, Nev.

733,082.—ABRADING COMPOUND—K. Sakurai, S. F.

733,292.—CAMERA—W. R. Smith, Napa, Cal.

733,301.—AMALGAMATOR—J. W. Swearington, Gaston, Cal.

733,097.—ELECTROMAGNET—I. G. Waterman, Santa Barbara, Cal.

733,705.—ELECTROMAGNET—I. G. Waterman, Santa Barbara, Cal.

Notice of Recent Patents.

Among the patents recently obtained through Dewey, Strong & Co.'s SCIENTIFIC PRESS U. S. and Foreign Patent Agency, the following are worthy of special mention:

COMPOUND FOR ABRADING TOOLS.—No. 733,082. July 7, 1903. Keizo Sakurai, San Francisco, Cal. This invention relates to the production of an artificial compound for use as a substitute for emery, carborundum and the like in the manufacture of grinding wheels and other abrading or polishing tools. Its object is to provide an abrasive compound possessing the following qualities: One which will possess great hardness and durability and which will not suffer deterioration through the generation of heat by friction, which will be homogeneous throughout and will not become worn unevenly, which will have an enhanced cutting power and which will not be liable to glaze or to have the pores clogged by the dust from the article being operated upon.

LOG OR LUMBER HAULING ATTACHMENT.—No. 733,007. July 7, 1903. Stephen H. Chase, San Jose, Cal. The object of this invention is to provide a mechanism which is driven from a shaft moving continuously in one direction, and which mechanism is reversible in all its parts by the use of belts and binder pulleys with automatically acting weights and levers and connections by which either of them may be thrown into or out of action, and is designed to provide an apparatus by which the hauling cable is operated to transport the load, and a return cable, which is connected with the main hauling cable, can be actuated to draw the main cable back to the collecting point after the load has been discharged, both operations and reversely the whole apparatus being effected by means of weighted binder pulleys, levers and connections by which the power derived from a shaft running continuously in one direction may be properly reversed.

STAMP AFFIXING MACHINE.—No. 733,074. July 7, 1903. Willis Earl Newton, Oakland, Cal. This invention relates to improvements in devices for automatically affixing stamps upon envelopes and of pasting labels upon packages, boxes and the like. Its object is to provide a simple, light, durable and efficient machine in which the stamps are drawn successively into a chamber beneath a vertically reciprocating plunger adapted to sever the stamps and affix the latter upon the previously wetted surface of the envelope.

Latest Market Reports.

SAN FRANCISCO, July 17, 1903.

METALS.

SILVER.—Per oz., Troy: London, 24¾d (standard ounce, 925 fine); New York, bar silver, 53¾c, refined (1000 fine); San Francisco, 53¾c; Mexican dollars, 41c San Francisco, 42½c New York.

COPPER.—New York: Standard, $13.62½; Lake, 1 to 3 casks, $13.62½@13 75; Electrolytic, 1 to 3 casks, $13.62½@13 75; Casting, 1 to 3 casks, $13.25@13 37½; San Francisco: $14.00. Mill copper plates, $17.00; bars, 18@24c. London: £57 5s spot per ton.

LEAD.—New York, $4.12½; Salt Lake City, $3.50; St. Louis, $4.00; San Francisco $4.50, carload lots; 4¼c 1000 to 4000 lbs.; pipe 5½, sheet 6, bar 5½c; pig, $4.75. London: £11 8s 9d per long ton=2.75c per lb.

SPELTER.—New York, $6.12½; St. Louis, $4.85; London, £20 15s per ton; San Francisco, ton lots, 6½c; 100-lb lots, 7c.

ANTIMONY.—New York, Cookson's, 9¾c; Hallett's, 8½c; San Francisco, 1000-lb. lots, 10c; 300 to 500 lbs., 11c; 100-lb. lots. 13@15c.

TIN.—New York, pig, $26.90@27.15; San Francisco, ton lots, 29½c; 500 lbs., 30c; 200 lbs., 30½c; less, 31c; bar tin, ℔, 32½c @35c. London, £123 spot.

PLATINUM.—San Francisco, crude, $18.00 ℔ oz.; New York, ingot, $19.00 per Troy oz. Platinum ware, 75@80c per gram.

QUICKSILVER.—New York, $44.50@46.00; large lots; London, £8 15s; San Francisco, local, $44.50 ℔ flask of 76½ lbs.; Denver, $49.50. Export, $43.50.

BABBITT METAL.—San Francisco, No. 1, 10c; No. 2, 7c; No. 3, 6½c; extra, 17½c; genuine, 35c; Eclipse, 37½c.

ALUMINUM.—New York, No. 1, 99% pure ingots, 35c; No. 2, 90%, 30c to 34c.

SOLDER.—Half-and-half, 100-lb. lots, 19½c; San Francisco, Plumbers', 100-lb. lots, 16c.

NICKEL.—New York, 50@60c ℔ lb.; ton lots, 45@48c.

STRUCTURAL MATERIALS.

IRON.—Pittsburg, Bessemer pig, $19.50 @19.85; gray forge, $18.60; San Francisco, bar, 3c ℔ lb., 3½c in small quantities.

STEEL.—Bessemer billets, Pittsburg, $29 50@30.50; open hearth billets, $31.50; San Francisco, bar, 7c to 12c per lb.

CHICAGO CURRENT QUOTATIONS.

LUMBER.—(Retail): Pine, ordinary sizes, $20.00@22.00; extra sizes higher; redwood, $22.00@23.00; lath, 4 feet, $4.25 @4.50; pickets, $19.50; shingles, $2.35 for No. 1 and $2.00 for No. 2; shakes, $13.50 for split and $14.50 for sawed; rustic, $26.00 @32.00.

NAILS.—Per keg (list prices): No. 20d to 60d, Wire, $3.25; Cut, $3.35; 10d to 16d, Wire, $3.35; Cut, $3.35; 8d, Wire, $3.40; Cut, $3.40; 6d and 7d, Wire, $3.50; Cut, $3.50; 4d and 5d, Wire, $3.60; Cut, $3.60; 3d, Wire, $3.75; Cut, $3.75; 2d, Wire, $4.00; Cut, $4.00. Special rates for carload lots.

LIME.—Santa Cruz, $2.25; Roche Harbor, $2.25 per hbl.

CEMENT.—Germania, $2.50 @ 2.75; Hewmoor, $2.90; Trowell, $2.90; Portland, $2.50@2.75 per bbl.

GENERAL SUPPLIES.

POWDER.—F. o. h. San Francisco: No 1, 70% nitro-glycerine, per lb., in carload lots, 15½c; less than one ton, 17½c. No. 1*, 60%, carload lots, 13½c; less than one ton, 15½c. No. 1** 50%, carload lots, 11½c; less than one ton, 13½c. No. 2, 40%, carload lots, 10c; less than one ton, 12c. No. 2, 35%, carload lots, 9½c; less than one ton 11½c. No. 2** 30% carload lots, 9c; less than one ton, 11c. Black blasting powder in carload lots, minimum car 728 kegs, $1.50 per keg; less car lots, $2 per keg.

CAPS.—3x, $5.50 per 1000; 4x, $6.50; 5x, $8; Lion, $9, in lots not less than 1000.

FUSE.—Triple tape, $3.60 per 1000 feet; double tape, $3.00; single tape, $2.65; Hemp, $2.10; Cement No. 2, $3.00; Cement No. 1, $2.65, in lots of 3000 feet and up.

CANDLES.—Granite 6s, 16 oz., 40s., 10½c ℔ set; 14 oz., 40s., 9½c.

CHEMICALS.—Cyanide of potassium, 98%-99%, jobbing, 24@25c ℔ lb.; carloads, 23@24½c; in tins, 35c; soda ash, $2.00 ℔ 100 lbs.; hyposulphite of soda. 2½@2¾c ℔ lb.; caustic soda, in drums, 3@3¼c ℔ lb; Cal. s. soda, bbls., $1.25@1.50 ℔ 100 lbs.; sks., $1.05; chlorate of potash, 12@13c; nitrate of potash, bbls., 10c; caustic potash, 10c in 40-lb tins; borax concentrated, 7@8c ℔ lb.; roll sulphur, 4@6c; powdered sulphur, 2@3c; flour sulphur, French, 2@3c; alum, $2.00@2.25; California refined, 2@2½c; sulphide of iron, 9c ℔ lb; copper sulphate, 5@7c; chloride of lime, spot, $2 50@2.75; sulphuric acid, in carboys, 66% B, 2¼c ℔ lb.; nitric acid, in carboys, 8c ℔ lb.

OILS.—Linseed, boiled, bbl., 48c; cs., 53c; raw, hbl., 46c; cs., 51c; Lucol oil, boiled, bbl., 44c; cs, 49c; raw, hbl., 42c; cs, 47c. Kerosene—Pearl, per gal., 20½c; Astral, 20½c; Star, 20½c; Extra Star, 24½c; Eocene, 23½c; Elaine, 26½c; Water White, in bulk, 14½c; Mineral Seal, iron bbls., 18½c; wooden bbls., 21c; cs, 24c; Mineral Sperm, cs, 26½c; Deodorized Stove Gasoline, bulk, 17c; do., cs., 23½c; 86° Gasoline, bulk, 21c; do., cs., 27½c; 63° Naphtha or Benzine, deodorized, in bulk, per gal., 16c; do., in cs., 22½ c; Lard Oil, E. W. S., bbl., $1.00; cs., $1.05; Neats-foot Oil, pure, hhl., 75c; cs., 80c; Sperm, crude, 70@60c; Natural White, 65c; Bleached do, 50c; Whale Oil, cs, 50@55c.

WHITE LEAD.—Per lb., in kegs: 500 lbs. and over at one purchase, per lb., 6c; less than 500 lbs., per lb., 6½c; in 25-lb. tin pails, ½c per lb. above keg price; in 1 and 5 lb. tin cans, 100 lbs. per case, ½c per lb. above keg price. Dry Lead—In bbls., 1 ton and over, 6c; do. in kegs, 6½c.

RED LEAD.—500 lbs. and over at one purchase, per lb., 6c; less than 500 lbs., 6½c.

LITHARGE.—Pure, in 25-lb. bags, 8 @9c per lb.

BONE ASH.—Extra No. 1, 5@6c per lb. No. 1, 4@5c.

BORAX.—Concentrated, 7@9c per lb powdered, 9@12c; fused, 25@30c.

BORAX.—Crystal, 7c; calcined, 25c.

MANGANESE.—Pure, ℔ lb., 60c.

MOLYBDENUM.—$2 per lb.

CHROMIUM.—(90% and over) per lb., $1.00.

BISMUTH.—Suhnitrate, per lb., $1.60.

MERCURY.—Bichloride, ℔ lb., 90c.

PHOSPHORUS.—(American) ℔ lb., 75c.

SILVER.—Chloride, ℔ oz., 90c@$1.00; nitrate. 55c.

ALUMINUM.—No. 1, 99%, small lots, 37c ℔ lb.; 100 lbs., 35c; 1000 lbs., 34c; ton lots and over, 33c, Pittsburg. No. 2, 90%, small lots, 34c; ton lots and over, 31c, Pittsburg.

URANIUM.—Oxide, ℔ lb., $3.50.

ZINC.—Metallic, chemically pure, ℔ lb., 50c; dust, ℔ lb., 10c; sulphate, ℔ lb., .04c.

COAL.—San Francisco, coast, yard prices: Wellington, $8.00; Seattle, $6.50; Coos Bay, $5.50; Southfield, $8.00. Cargo lots, Eastern and foreign: Wallsend, $6.50 Brymbo, $7.50; Pennsylvania, hd., $14.00 Scotch, $8; Cumberland, $12; Cannel, $9.00; Welsh Anthracite, $11.50; Rock Springs, $9.50, long ton; Colorado Anthracite, $14.00. Coke, $10.50 per ton in bulk, $13 in sacks; Sunnyside, $8.50, long ton.

(These prices are wholesale, f. o. b. San Francisco, unless otherwise noted.)

WANTED.

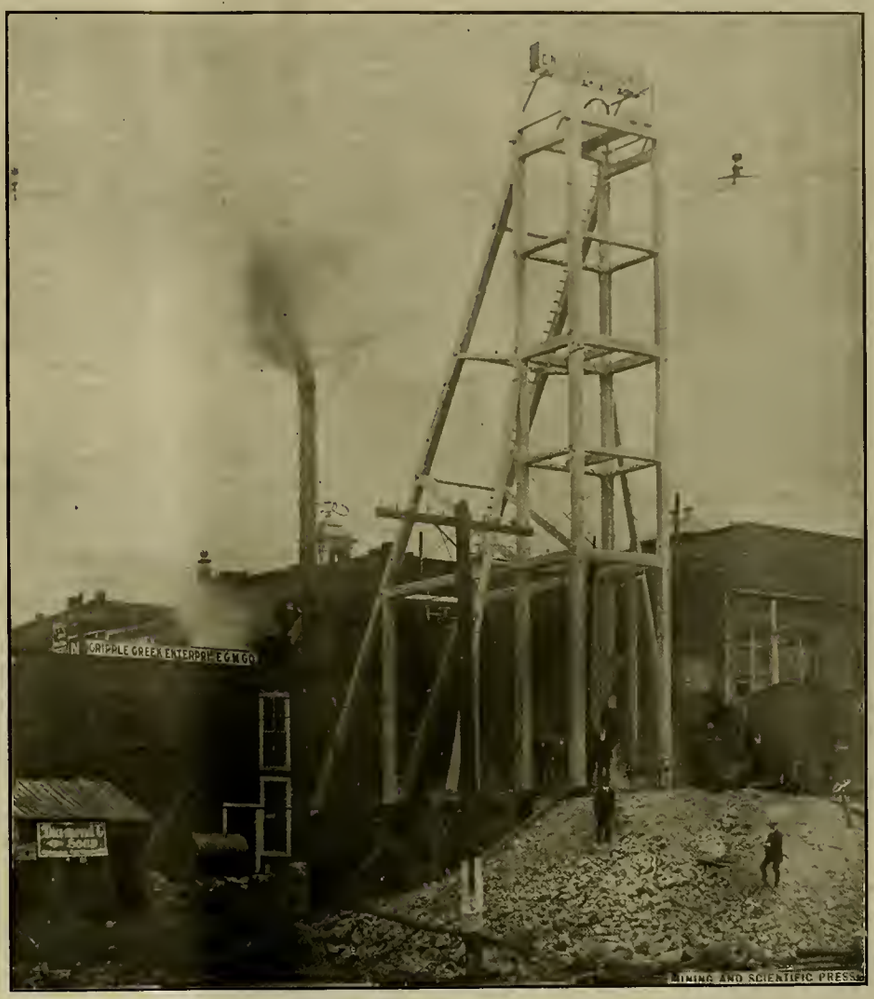
CAPABLE ENGINEER OF GOOD STANDING and experience would like to purchase an interest in an established engineering business—mining or civil. Only a business capable of expansion and doing high grade work is desired. Address "Experience," care of Mining and Scientific Press.

WANTED--MILL TAILINGS.
Gold, silver or lead, in New Mexico, Arizona or old Mexico. Will buy or lease. Give location, quantity and value. A. E. VAN VELSAN, Telluride, Colorado. Box 181.

MINING STOCKS WANTED.
If you are a stockholder in any good going mining company and want to sell your shares
WE CAN GET YOU CASH.
Send for our price list of 500 stocks. It tells what we will buy and what we will sell.
CATLIN & POWELL, M 94, 35 WALL ST. NEW YORK.

MINING AND SCIENTIFIC PRESS.

Whole No. 2244.—VOLUME LXXXVII. Number 4. SAN FRANCISCO, CAL., SATURDAY, JULY 25, 1903. THREE DOLLARS PER ANNUM. Single Copies, Ten Cents.

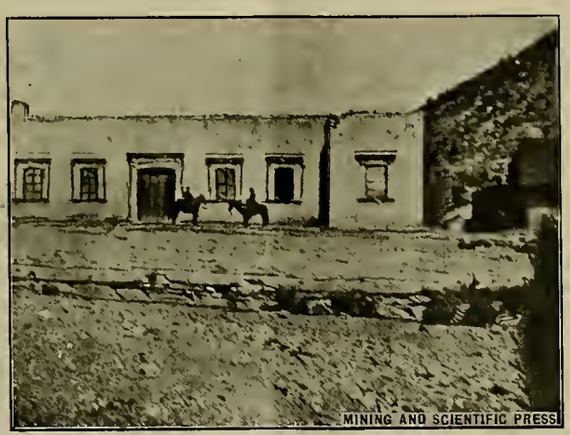


A Novel Head Frame.

There are always new departures in the construction of head frames, many types of which have been described and illustrated in the past in the MINING AND SCIENTIFIC PRESS. The accompanying illustration is that of a new frame constructed by the Cripple Creek Enterprise G. M. Co. of Cripple Creek, Colo. The frame is 60 feet high, the main timbers being 12x12 inches. It is very simple in construction, being of the four-post rectangular type, with the usual back braces. In this frame side braces have also been placed, owing probably to the rather narrow width of the frame, and to the further fact that the entire frame is constructed on a foundation of posts and sills and does not set on the solid rock, due to lack of dumping facilities. It will also be noticed that but one sheave has been provided, the evident intention being to hoist through a single compartment only. The frame is made more rigid by cross tie rods, which pass through the timbers, and are provided with washers and nuts on either end. The bucket is handled with a trip rope made fast to a heavy cross tie at the rear of the shaft.

This method of handling rock through vertical shafts is very commonly practiced in Colorado, as well as elsewhere. It is customary to arrange some sort of door or apron over the shaft to prevent rocks falling back into the shaft when dumping the bucket. Doors so arranged are easily handled by the topman, by means of rope and counterbalance, which assists in equalizing the weight of the door.

There are numerous bodies of ore known to exist under the streets of Cripple Creek, but no one has been permitted to mine under these thoroughfares without first making a satisfactory arrangement with the city authorities. This company has a lease from the city of Cripple Creek to mine under the city by paying the city certain royalties. They have their shaft down 210 feet and will sink 300 feet farther, and are now crosscutting at the 200 level. They have two veins that run from $138 to $765 per ton. One of the veins is 18 inches wide and the other 3 feet wide. They have recently installed an 8-drill compressor, and it is the intention to put in a 125 H. P. boiler.



C. E. Miesse is treasurer, D. Hanley is president, and L. H. Allan of Cripple Creek, Colo, secretary.

Wet vs. Dry Crushing.

Dry crushing is being tried in Rhodesia, South Africa, in the treatment of gold ores by cyaniding. This method of treating the average quartz ore, it would seem, had had a sufficient trial to demonstrate that the process is not all that could be desired, and in the case of New Zealand, after a trial lasting several years, it has been found that wet crushing produced better results, and that a higher saving was possible by wet than by the dry crushing method, with no materially increased cost for the former method. In the past dry crushing mills, which have been used in some localities in the United States where preliminary roasting was necessary, have been found very detrimental to the health of the workmen, but the recent introduction of exhaust fans, which take the dust from the batteries as fast as created, has largely reduced this objection to a minimum. Where a wet process is to be employed in the subsequent treatment of the ore, it has not been demonstrated that dry crushing is advisable. It is true that prior to the successful treatment of slimes after wet crushing, that dry crushing was superior to wet on ores containing a low percentage of sulphides and no coarse gold; but since slimes can now in most instances be successfully treated, dry crushing is practically a process of the past.

The American Mining Congress.

The sixth annual session of the American Mining Congress is to be held at the cities of Deadwood and Lead, South Dakota, Sept. 7th to 12th, inclusive. During the meeting addresses will be made, technical papers read and excursions taken to the various points of interest in the Black Hills. These trips can be taken without hardship or inconvenience, as railroads run to or near all of the larger mining, milling and smelting plants, as well as to the various points of scenic or geological interest; of which there are many. Visitors, it is stated, will be permitted to see the underground workings of the Homestake mines—a privilege that has been denied for many years.

Making Records in Mine Work.

Rapid work in excavating and securing mine openings by means of timbers or otherwise, where time is the basis of comparison, is only accomplished under favorable conditions. Work which is actually not quickly done when measured by the number of days required to accomplish it, may be considered so, however, when comparison is made with similar work elsewhere. Favorable conditions comprise rock not too hard, no trouble from water, or other extraneous causes, efficient and diligent workmen, good tools and competent supervision, and there is much in the last factor. Competent workmen are not always diligent, nor can good workmen do good work with poor or insufficient tools. The statement that a certain shaft was sunk a given number of feet in a certain number of days does not indicate that the work was accomplished more quickly than it should have been, nor does the statement that an average of but 6 inches per day was made in a certain drift, signify that the ground was unusually hard, or that there was some other feature about the work which seriously retarded the work. The fact that a given time, be it long or short, was required for the accomplishment of certain work, however, suggests that the conditions under which it was accomplished were either unusually favorable or particularly onerous. Under any circumstances, work is accomplished the most quickly under efficient superintendence, with the most capable workmen. The personal equation is a very large one, and when it is accentuated by reason of inferior and inexperienced workmen taking the places of those who are competent, the best work cannot be performed in the shortest given time. Some excellent work has been accomplished under the premium system, which is one of the best and fairest ever introduced in a mine. When the wage rate is fixed at a good and reasonable figure, and the task is set at a mark within the possibility of accomplishment by the exercise of reasonable industry, the offer of a premium for the accomplishment of additional work usually acts as a stimulant to all concerned in the task. Moreover, under such a system there can be no laggards. All must work faithfully for the good of all. If one man in the crew is incompetent or attempts to "soldier" on the others he is quickly called to task, and he must either "keep up his end" or quit the job to give place to another who is able and willing to do his honest share of the toil. In this manner the best results are obtainable as to speed, but this system of working also requires the most careful supervision, for the reason that the workmen in their desire to earn the premium are sometimes inclined to slight what may seem to them small details, and a shaft or drift under such circumstances is more than likely to get out of alignment, and the object of the premium system thereby defeated in the end.

Prospects in the Yukon Basin.

Recent advices from the Northwest country, Alaska and the Yukon Basin, are to the effect that some of the much-talked-of new placer districts are too poor to pay by ordinary mining methods, and it is doubtful in some cases whether they can be worked at a profit by any known method. The notoriety which some of these districts, both old and new, have gained appears to be due to the stories told by certain well known prospectors who have a reputation for finding rich diggings. A word from one of these men concerning a new district, particularly if it be favorable, is quickly magnified and the "rush" is on. Men tramp across those northern wilds without blankets, and often without food, taking a desperate chance of living on the bounty of another class that packs more provisions and outfit than it can care for. There is no promise of fighting over the staking of the Tanana country prior to the stampede to that section, as the diggings are not rich enough to warrant it.

A SPECIAL session of the Colorado Legislature is announced for the coming week, in anticipation of which Governor Peabody has been requested by labor organizations to recommend the passage of an eight-hour law. The last Legislature failed to pass this law, though urgently appealed to to do so. This new attempt is being strongly opposed by the mining and reduction companies generally. Thus far, in most cases where legislative bodies have interfered with the natural adjustment of the labor problem, their efforts have either been abortive or the laws have become a dead letter. In some instances the laws passed have failed to stand the test of the courts, having been declared unconstitutional. In Western Australia the government sought not only to fix the hours, but also the wage rate, and the result has been the closing down of many of the low-grade mines, they being unable to meet the short hours and high wages.

Probable Extension of the Rand Banket.

In a study of the gold-bearing conglomerates of the Rand in South Africa many theories have been advanced with a view to locating a possible extension of these beds. The anticlinal theory is the one now finding greatest favor. In itself, the theory is plausible enough, but at a distance one can form no positive opinion. The mining engineers and geologists who are in the field should be able to determine whether or not there is a reasonable probability of the anticlinal theory having any foundation in fact. It is properly assumed that the conglomerates, and sandstones in which they are intercalated, being of sedimentary origin, must have been deposited in a nearly horizontal position. It is also assumed by some for lack of better evidence that "these sediments were derived from highlands existing somewhere to the eastward, probably in the Indian ocean." This may have been the case, but it seems more reasonable to suppose that they were derived from some region much nearer than the nearest point on the shore of the Indian ocean, a distance of about 200 miles. Conglomerates are usually somewhat local in occurrence, and it seems unlikely that the conglomerates derived the materials of which they are composed from so great a distance.

The bankets with the sandstones are uptilted, dipping to the southward, usually at about 45°, at and near the surface, the dip flattening with depth and distance from the outcrop. That these beds extended farther to the northward, but that their northward extension has been removed by erosion, there can be no doubt, and whether the fold in the Witwatersrand district was a monocline or a synclinal fold is not material, but it is important to know whether these beds are repeated with a northerly dip, or whether the formation thinned out to the northward and never had an existence in the region where there might be a possibility of their being found. These conglomerates, unlike those of South Dakota, did not derive all their gold, if, in fact, any at all, from a pre-existing auriferous formation, but the gold was deposited in the cementing material in a manner similar to the deposit of gold in crushed zones of rock in situ elsewhere. This fact is of importance and has a direct bearing upon the value of any conglomerates which possibly may be discovered to the northward, for should such discoveries be made, it is a question whether or not they would prove sufficiently valuable, if found gold bearing at all, to constitute payable ore. The relative size of the pebbles in the conglomerate should convey some idea of the direction from which the detritus was derived, but as far as noticed no one of the numerous writers on the Rand mines has mentioned any appreciable difference in the size of the pebbles composing the conglomerate. However, a knowledge of the source of the conglomerate is not nearly so important as an idea of its probable northern extension on the opposite side of the fold.

VISITING mining men are invited to make their headquarters at the MINING AND SCIENTIFIC PRESS offices when in New York, Chicago, Denver or San Francisco. At the New York City office, 720 Park Row building, Mr. W. S. Bullock, the Eastern manager, will be pleased to welcome visitors and be of any possible service to them. Similarly, the Chicago manager, Mr. L. A. Greene, 1115 Monadnock block, Chicago, and Mr. E. J. Moore, the Colorado manager, 606 Mack block, Denver, will take pleasure in affording visitors such facilities as are at their command. The same cordial invitation is extended to visitors to the home office, 330 Market street, San Francisco, Cal.

CONCENTRATES.

A PROGRESSIVE MAN must needs often change his views. The man who "knows it all" is a hopeless case, and has outlived his usefulness.

THE specific gravity of sheet iron is 7.7 and that of sheet steel 7 854. A cubic foot of iron weighs 480 pounds, and of steel 489.6 pounds.

RESERVATIONS in mining patents are void unless the same are authorized by law, and after issuance the property rights are governed by State laws.

SOUTH AFRICAN mining claims are bounded by vertical lines. The extralateral and "apex" right is recognized in no mining country on earth, except Bolivia, S. A.—and the United States.

IODINE is extracted from the ashes of seaweed, especially those varieties occurring on the coasts of Japan, France, Scotland and Norway. Iodine is also obtained from Mexico and Chile in the mineral iodyrite (AgI).

THE locator of a mining claim may perform $500 worth of work on his claim as speedily as circumstances and conditions will permit—within a week after discovery, if desirable—and he may then apply for patent.

GOLD was first reported in Georgia, at Duke's Creek, near Nacoochee, about 1829. Another report places the first find near Dahlonega, earlier in the same year. Gold was discovered in Alabama about the same time.

THE mill man who steadfastly holds to the old-time methods of thirty years ago has much to learn, for there are many things about mills he does not know, and the amusing part of it is he does not know that he doesn't know.

THERE are numerous automatic ore samplers on the market and in use in sampling works, mills, etc. They all work mechanically, cutting out a portion of the sample or continuously taking a certain percentage of all the sample.

TO DETERMINE the actual capacity of an air compressor in free air per minute requires a painstaking test. It may be obtained very closely by taking indicator cards of the air cylinder, from which the effective stroke can be determined.

A MINING CLAIM cannot be held for debts contracted by a lessee or person working the same under bond in California, if the owner of the claim post a notice that he will not be responsible for any debts contracted by the person or persons operating the mine.

CONVEYING BELTS can be used to great advantage about quartz mills and other reduction works, carrying the ore in the various stages of the operation where gravity cannot be employed. They are also useful in disposing of waste coming to the mill with the ore.

THE loss of one-fifth ounce of quicksilver per ton of ore treated is excessive; probably too much "quick" is being fed, rendering the plates too soft, with a consequent loss of mercury. The loss of quicksilver will probably be proportionally more on a poor than on a rich ore.

THE dial of a watch may be employed as a compass on any day when the sun is visible. Point the hour hand directly at the sun, and in the northern hemisphere north of the 23rd parallel, south will be midway between the hour hand and the midday mark XII on the dial of the watch.

IT IS always advisable to have extra parts about a quartz mill, particularly those subjected to rapid wear or breakage. In some modern mills an extra cam shaft, with cams in place, is kept in readiness in the event of a shaft or cam breaking, that no unnecessary time need be lost in replacing the broken one.

IT is thought by some authorities that the diamonds found in Brazil alluvial deposits were derived from the degradation of the flexible sandstones found in the vicinity of the mines, but that they were deposited contemporaneously with the sand now forming these rocks. Diamonds are also known to exist in the conglomerates of that region.

BROMINE is extracted from sea water and saline springs—the important occurrences of the latter in the United States being in Michigan, Ohio, Pennsylvania and West Virginia. It is mainly marketed in the form of potassium bromide (KBr). Bromine is also obtained from the mineral embolite, a silver chloro-bromide, which is abundant in Chile.

THE steam turbine is considered to be a commercial success. The gas turbine is the newest device. Its success is yet problematical, and, ultimately, seems to depend upon ability to produce a continuous combustion of gas, under pressure and under complete control. This sounds small, but means much, doing away with the boiler, and relegating water from the business of supplying power as completely as the oar has been relegated from the business of propulsion.

GARNIERITE, or noumelte, is a hydrated silicate of nickel and magnesium, represented approximately by the formula, $H_2(Ni\ Mg)\ Si\ O_4 + aq$; amorphous; soft and dull; color, bright apple green to nearly white; specific gravity, 2.5. It is an important ore of nickel, principal occurrence being near Noumea, New Caledonia island, in serpentine associated with chromic iron and steatite.

THE power required to run a wet crushing gold mill of the usual design varies somewhat, owing to distribution of power, and the amount of friction to overcome. The power required in a small mill is proportionately more than in a large mill. Forty horse power should be sufficient to run an ordinary 20-stamp mill, comprising the battery of twenty 1000-pound stamps (100 drops per minute), one rock breaker and eight concentrators.

A SINGLE machine drill, 3½-inch piston, working at normal speed under ninety pounds pressure per square inch, will use about 160 cubic feet of free air per minute. A number of machines, however, may be kept constantly running with proportionally less air. For instance, ten drills of the same size operating under similar conditions will use but 1120 feet of free air, equivalent to an average of 112 feet per machine. This takes into consideration leakage, friction, etc.

ROADS AND DITCHES, as well as the construction of buildings and the installation of machinery, when for the benefit of an unpatented claim, may each and all be applied on assessment work on the same; but a ditch constructed and actually reaching a claim, which is not used in connection with the same and is not intended for use on the same, cannot be applied in this manner. The bringing of tools, etc., upon a claim is not permissible as a charge to assessment work.

SHAFTS may be sunk in quicksand or other wet running ground by freezing the ground by means of the ammonia process. In Alaska the placer ground is usually found already frozen and miners thaw it by building fires in their shafts and tunnels, or by means of steam-thawing machines. Frozen ground is difficult to cut, particularly when in the form of gravel. As sand, however, it can be removed by use of chisel-shaped digging tools.

FOR filling in grooves of transmission pulleys various materials have been used, such as tarred oakum, jute yarn, hard wood, india rubber and leather, but that which is said to give the greatest service consists of alternate segments of leather and rubber, soaked in tar and packed in the groove, and then, when dry, turned out to a true surface. Where a running rope is subject to considerable side vibration the flanges are sometimes lined with leather riveted on. These protect the rope from excessive wear.

THE area of a circle is equal to the circumference times the diameter, divided by 4 or multiplied by 0.25. The circumference squared times 0.07958 also equals the area, or the diameter squared times 0.7854. To find the area of an annular ring formed by the space between two concentric circles, add the two diameters and multiply the sum by their difference, and this product by 0 7854. The areas of circles are to each other as the squares of their diameters.

THE rock sample from Missoula, Mont., is quartzite of fine and uniform texture with some secondary silica developed in places, the crystalline structure of which obliterates the normal granular texture of the rock. The yellow mineral is iron oxide. "Free gold" can be seen in the specimen. The fine-grained soft material with black color is probably the filling by fine granular silica and graphite of a pre-existing cavity in the rock. There is no indication that the rock does or will contain copper in depth, though such might prove to be the case. The rock should amalgamate readily, and, if the fine gold is not saved by that process, the tailings would probably be well adapted to cyanidation.

SCHOOL LANDS in the State of California may be declared mineral upon the presentation of affidavite or otherwise to the satisfaction of the Surveyor-General that any portion of the sixteenth or thirty-sixth section belonging to the State is valuable for its mineral. The Surveyor-General shall then not approve any application for the purchase of the same, nor shall the Register of the State Land Office issue a certificate of purchase therefor until the question of the character of the land shall have been determined by a court of competent jurisdiction, and the sixteenth and thirty-sixth sections of any township (school lands) of California, when determined to contain valuable mineral, are subject to location of mineral claims under the Federal laws.

COPPER ORES generally are dissolved by digesting in c. p. nitric acid. Sulphur separating in the process will contain little or no copper. One of the most reliable methods of determining the percentage of copper in ores is by the electrolytic method. The conditions essential to proper working of this process are a sufficiently dilute solution, not too much free acid, and a low current of electricity. Hydrochloric acid must not be present, nor much nitric acid. The presence of much antimony, bismuth, arsenic or silver will cause the copper to be impure and will give misleading results. Bismuth is particularly obnoxious, a small amount giving a higher apparent percentage of copper than really exists. Fortunately they are rarely present in amounts sufficient to produce annoying results.

THE Federal Statutes permit assessment work to be done outside the boundaries of an unpatented claim to count as work actually performed upon the claim when it is evident the work so performed is for the benefit and ultimate development of the claim. Consequently work done outside the claim upon another claim which is patented, if for the benefit of the one unpatented, may be considered as work done upon it. (Hall vs. Kearney, 18 Colo., 503; 33 Pacific Reporter, 373; Sherlock vs. Lighton, 9 Wyo., 297; 63 Pac., 580; also Little Dorrit G. M. Co. vs. Arapahoe M. Co., 71 Pac., 391—a recent Colorado decision.) When one owns a group of contiguous claims it is not necessary that all of the group should be patented at one time. The several claims may be patented singly and at different times.

IN the case of the Northern Pacific Railway Co. vs. Soderberg, the Supreme Court of the United States decided a question that involved what constitutes mineral lands, under the act of Congress of July 2, 1864. The case arose out of an application by the railroad company for an injunction to restrain the appellee from removing or disposing of granite from a quarter section of land in the State of Washington, of which he had taken possession under a mineral location. The Supreme Court decided in favor of Soderberg, holding that the legislation in question coincided with rather than opposed the overwhelming weight of authority to the effect that mineral lands include not merely those that are metalliferous, but also all such as are chiefly valuable for their deposits of a mineral character which are useful in the arts or valuable for purposes of manufacture.

THE "pounding mill," as the stamp mill was originally known, is supposed to be of European origin, and was in use in Europe, before the discovery of America, for the pulverizing of ores. One of the first stamp mills built in the United States was one of six stamps, erected at the Tellurium mine in Virginia in 1836. These stamps weighed 50 pounds each. The following year a similar mill was built at the Haile mine in South Carolina. These mills had wooden stems shod with iron. The dies were iron. They were similar in mechanical working to modern mills. The stems were square and did not revolve. The cams worked in slots cut in the stems. It is stated that a 10-stamp mill of this primitive design could be constructed for about $150 and have a capacity of about 300 to 500 pounds of ore per stamp daily. Amalgamation was accomplished on a strip of copper plate the width of the battery and a foot wide.

A STEAM ENGINE or air compressor indicator is a device by means of which the fluctuations of pressure and volume of the steam within the cylinder may be measured. It also shows the work done and the power developed by the action of the steam upon the piston and the gross work performed by the transformation of heat energy. The dynamotor is an instrument employed to measure the net work of the engine, the work done and power available at the shaft of the engine for actual application. The difference between the measures of these two indicators is the energy lost, due to resistance in the machine itself, the sum of frictional resistance and the loss due to back pressure on the exhaust side of the piston. The indicator is attached to a pipe connecting with the cylinder of the engine, and the variable pressure of the steam during every part of the stroke is recorded on a card by a pencil which forms part of the indicating instrument. The indicator itself consists of a small cylinder with movable piston, the latter held by a spring, and this is compressed or extended as the pressure varies, this being indicated on the card.

PHOSPHORESCENCE is a property possessed by a variety of minerals. The continued emission of light by a substance (not incandescent) produced, especially after heating, exposure to light or to the electric current is called phosphorescence. The mineral fluorspar (calcium fluoride) is highly phosphorescent after being heated to about 300° F. The several varieties of fluorspar emit light of different color. Chlorophane, one variety, emits an emerald green light; others purple, blue and reddish tints. The phosphoresence may be observed in a dark place by subjecting the mineral to heat below redness. Some varieties of white marble emit a yellowish light upon slight heating; tremolite, a variety of amphibole, also emits phosphorescent light. Some minerals, naturally phosphorescent, appear to lose this peculiar property upon being heated, but it may be restored by passing an electric current through the calcined mineral. Some varieties of calcite, fluorite, apatite (calcium phosphate) and some specimens of diamond, which are not phosphorescent, may become so by application of electricity. Exposure to rays of the sun often produces a very pronounced phosphorescence in many diamonds, though some diamonds appear to be wholly destitute of this property. It has been noticed that exposure of the diamond to the blue rays of the spectrum intensifies the light, while exposure to the red rays causes it to rapidly fall and disappear.

Igneous Rocks: How to Identify Them.

Written for the MINING AND SCIENTIFIC PRESS by CHARLES J. O'BRIEN, M. E.

The matter, perhaps, in which the average prospector or miner is least apt to show concern is in the name which he bestows upon the rock formations among which he pursues his vocation. As a general rule, his nomenclature is apt to be more fanciful than exact. In mineralogy he evinces, perhaps, somewhat more interest. He does, however, consider it proper to christen the hanging and foot walls of his lode, and his error is not always so palpable as that of the miner who recently stated that his hanging wall was granite, while his foot wall was syenite.

It is, of course, neither necessary nor advisable that the miner should try to make fine but useless distinctions. The comparatively few rocks, however, which constitute the ore-bearing series can be distinguished with reasonable certainty after a little practice, prefaced by an intelligent and systematic study of their composition and characteristics, mode of occurrence, etc.

This paper is addressed to the task of supplementing the ordinary text-book descriptions of the more common igneous rocks with a few practical hints for identifying them without microscopical examination. As a rule, petrographical text-books are far less explicit than could be desired upon those points which enable us to identify a rock in the field. To this may be added the fact that scarcely two authors coincide in all particulars, at times touching but lightly on essential characteristics, lingering over those of only secondary importance. As a rule, there are seldom more than one or two minerals which, combined with the mode of occurrence, determine the identity of a rock. When this is the case it should be made plain in works purporting to be text-books, and when other minerals, or forms of the same mineral, are merely subsidiary, this fact, also, should be plainly brought out.

Let us take trachyte as an instance to the point:

I. C. S. Text Books: Of the acid group, trachyte is one of the most common forms. It is usually a light-colored rock, and has a peculiar characteristic rough feel, on account of the fact that the ground mass is composed of sanidin, in which are needle-like crystals of the same material. Augite is always present, and other minerals may occur associated with it, especially boitite.

Le Conte: Orthoclase; crystals of sanidin; glassy magma, with or without embedded crystals.

Kemp: Chief feldspar orthoclase; biotite (or) (and) hornblende, (or) (and) augite.

Dana: After orthoclase, shows that trachyte may have sanidin, forming sanidin-trachyte, or it may have hornblende, augite or biotite.

Now, to the student the main fact is that trachyte is an orthoclase lava; its name is, therefore, determined by its feldspar and its mode of occurrence. Thus, any orthoclase lava is trachyte, and other minerals, should they occur, may be regarded as subsidiary, since they do not change the character of the rock.

The subjoined table gives a list of the more common igneous rocks, arranged so as to have those of essentially the same composition in the same line:

	LAVAS.	INTRUSIONS.	PLUTONIC.	FELDSPAR.
ACIDIC	Trachyte (Augite, etc.).	Felsite.	Syenite (Hornblende).	Orthoclase (potash).
	Rhyolite (Quartz-trachyte).	Quartz-felsite (Quartz-porphyry).	Granite (Quartz, mica).	
BASIC	Andesite (Hornblende).	Diorite (Hornblende).	Diorite (Hornblende).	Plagioclase. Oligoclase (Soda-lime).
	Dacite (Quartz-andesite)	Quartz-diorite.	Quartz-diorite.	
	Basalt (Augite, olivine).	Diabase (Augite).	Diabase, Gabbro (Augite).	Labradorite (Lime-soda).
	Occurring only as overflow; fine-grained and glass-bearing.	Intrusions—dikes, sheets, bosses, laccolites; fine-grained.	Occurring in underlying masses; coarsely crystalline; uncovered by erosion	

TO IDENTIFY THE FELDSPARS.—The important feldspars in igneous rocks are the potash feldspar, orthoclase, and the soda-lime and lime-soda feldspars, called collectively plagioclase. Orthoclase has two cleavages at right angles, while the cleavage angles of plagioclase are oblique. The two systems look much alike, however. Where the ground mass is in a somewhat carious condition it may be coarsely broken up in a mortar, when the crystals will separate in a more or less perfect state, and may then be studied to better advantage. The crystals may be examined for the fine straight ridges or striations peculiar to plagioclase. All of these tests may fail, however. Perhaps the most speedy and reliable test is to try a fine, clean splinter before the blowpipe. Orthoclase fuses with extreme difficulty, plagioclase with comparative ease.

HORNBLENDE AND AUGITE.—Look for 4-sided and 8-sided outlines in augite; acute rhombs and hexagons in hornblende. The cleavage angle of hornblende is about 124°, that of augite about 87°. There is thus little difficulty in distinguishing them, even when the crystals are small, should they be well crystallized.

THE MICAS.—The micas of most general occurrence are muscovite (white mica). and biotite (black mica). Often occur in disseminated scales, sometimes as aggregates. Try lifting an edge with the knife point. The laminæ are flexible and elastic; sometimes have a green tint, due to alteration. Laminæ have a tendency to scale off upon weathering.

OLIVINE (CHRYSOLITE).—Occurs in irregular grains and nodules, disseminated throughout the magma of basaltic rocks; sometimes looks like broken pieces of green bottle glass, but may be yellowish, or brownish, from incipient oxidation. Very hard.

QUARTZ.—Generally colorless or bluish, in irregular grains or nodules, but sometimes partly crystallized. Cannot be scratched with the knife or fused before the blowpipe.

This completes the list of determining minerals in the classification of all the common igneous rocks—certainly the most important of them, unless we except phonolite, which is a rare rock.

It should be borne in mind that igneous rocks are more or less changed for varying depths below the surface, and this is especially true where these rocks are contiguous to veins or dikes. A basic rock containing considerable iron, like the average diorite or andesite, weathers to a red or brown color on the surface. Below this, the zone of complete oxidation, we shall encounter a zone in which green is the prevailing color, the dark silicates having mostly changed to chlorite. At a still greater depth we come upon the gray, unaltered rock.

In classifying a rock, therefore, the first step should be to ascertain the condition of the specimen—whether altered or not—and to try to form some idea of its original appearance. The student should not be misled by colors, because, as shown, a rock may be of several different colors, corresponding to different stages of decomposition or metamorphism.

The next step should be to ascertain the different modes of occurrence. A granitoid structure is almost invariably the characteristic of the primeval or abysmal (plutonic) rocks, though erosion may cause them to outcrop or even to show considerable superficial areas. Let it be borne in mind, however, that quartz porphyries sometimes simulate the texture of granitoid rocks closely enough to deceive anything short of a close scrutiny. Plutonic rocks have a characteristically granular texture, which is generally coarse, but may be somewhat fine; but the regularity and uniformity in the size, number and distribution of the several minerals distinguish them from quartz porphyries. Again, although the crowding together of the minerals prevents them from developing fully their respective crystal forms, the feldspars always show their cleavage planes distinctly, while the feldspar of quartz porphyries is fine-grained or amorphous.

Diabase differs from other granitoid rocks in that the feldspars are automorphic—that is, their crystal forms are not modified, as in granite, by the accompanying minerals. The feldspars are lath-shaped and form a network the meshes or interspaces of which are occupied by augite, the other essential constituent of the rock.

Intrusive rock masses usually assume forms that make their classification obvious, even at a distance. Where cuts or faults have exposed them they are sometimes seen as long, relatively narrow ribbons, called sills—which is but another name for the cross-section of an intruded sheet. Laccolites are rounded, often flattened, domes; but instances are not wanting of denuded cones and spires reaching to a great height, so attenuated that they could by no possibility have been projected upward without lateral support, yet so hard and impervious as to resist the agencies which have worn away hundreds of feet of the circumjacent rock, as well as an unknown thickness above them. Dikes are another common form, but these should be distinguished from mere cracks or fissures which have been filled from above by overflows. Subsequent erosion may strip the overflow, leaving what appears to be the outcrop of a dike, or of a series of dikes.

Lavas may be recognized as superimposed bodies of rock covering considerable areas, and having a fine-grained or glassy texture. Of course, a lava may be covered by a subsequent overflow. Probably the lava having the most characteristic mode of occurrence is basalt, which is seen rising in successive steps or terraces, having well-defined angles, and often faced with rows of hexagonal columns.

In fine-grained or glassy rocks—intrusive or eruptive—it is, course, impossible to study the crystals, unless the rock be porphyritic, in which case the crystals are an index to the magma. As a rule, orthoclase rocks are light-colored and quite hard, as well as fusible with difficulty. The dark silicates occur sparingly, or not at all. Plagioclase rocks, on the other hand, are prevailingly dark—some shade of gray, when unaltered. They are easily scratched with a knife, fuse readily, and the ratio between the light and dark minerals approaches a parity.

There are, however, diorites and andesites which are light in color, but these can readily be distinguished from orthoclase rocks by their fusibility. There is little difference between diabase and basalt, but the former does not occur in overflows. Basalt of the typical kind is porphyritic with olivine, and sometimes contains a brown variety of hornblende, which is peculiar to basaltic rocks. Diabases sometimes contain olivine. These are very basic rocks, dark-colored and heavy.

Comparing the textures of intrusive and eruptive rocks, the former are apt to preserve the even and regular distribution of minerals which characterize their plutonic prototypes. Eruptive rocks, on the other hand, present a varied and uneven texture. Such crystallized minerals as may occur are irregularly distributed, being much more abundant in some places than in others, even in a small specimen. The magma may be more or less glassy.

There are, of course, all degrees of variation from the typical rocks of any series. Thus, there is micaceous granite, mica-diorite, soda-rhyolite, etc., besides the multitudinous distinctions made by petrologists; but the student who has learned to classify the typical rocks with reasonable accuracy will be able to deal with their variations.

Another class of rocks important in mining is the metamorphic series, especially the schists, but their consideration is not permissible within the limits of this paper.

Precipitation of Gold From Cyanide Solutions.

TO THE EDITOR:—Concerning the precipitation of gold from cyanide solutions by acidulating same with sulphuric acid and precipitating the gold by means of sheet zinc, in applying the method there are some fundamental principles which must be observed, and to carry these through will entail a cost which, in my opinion, will make the method prohibitive from this standpoint alone.

To overcome the normal working alkalinity of an ordinary cyanide mill solution and produce a degree of acidity which will give precipitation takes from 3 to 8 pounds of commercial sulphuric acid per ton of solution, according to the strength of cyanide solution and the amount of protective alkali used. Commercial sulphuric acid, delivered at most of the Western plants, costs from 3 cents to 4 cents per pound. The average cost, then, for acidulation alone would be 15 cents per ton of solution. The solution once acidulated would require to be brought back with alkali to its normal working degree of alkalinity before it could be used on the ore again. This practically means the neutralization of the added acid with an equivalent of caustic soda, and would cost approximately 24 cents per ton of solution, or a total cost between acid and alkali of 39 cents per ton of solution. Add to this the cost of the zinc consumed by the acid, which will bring the total cost for precipitation alone to considerably over 40 cents per ton of solution. In practice the quantity of solution to ore varies greatly, from ½ to 1 part of solution to 1 of ore. Take the best condition, ½ solution to 1 of ore, and the cost for precipitation per ton of ore will at least be over 20 cents per ton for chemicals and zinc only. Against this place the cost for precipitation on zinc shavings in the usual manner, which varies from 3 cents to 12 cents, depending on the strength of solution used and the value of ore treated. Besides the prohibitive cost of this process, it has other disadvantages. When a cyanide mill solution is rendered acid, a large quantity of cyanides (of copper, iron, zinc, manganese, etc.) is precipitated. These would necessarily be collected with the gold precipitated and would give a product much more impure and harder to refine than the ordinary gold slimes from the zinc box.

There are other features in connection with this process which would have to be considered in discussing the same minutely, such as the regeneration of a certain amount of cyanide, i. e., part of the cyanide which goes to form the double cyanide, all of which is more than counterbalanced by the loss of cyanide by volatilization, together with the loss of

cyanide combined with the metals thrown out on acidification, the latter loss being recoverable to a certain extent by other methods (in regular practice), the gradual fouling of solution with alkaline sulphate, and the increased cost for handling solutions by this method over the general zinc box method. But the few points discussed in detail above are, in my opinion, sufficient to condemn the method.

Denver, Colo., July 18. WILLIAM ORR.

From Parral to Guadaloupe y Calvo, Chihuahua, Mexico.

Written for the MINING AND SCIENTIFIC PRESS by H. Z. OSBORNE.

In January and February of the present year the writer made a visit to Mexico, which included the Parral district, in the State of Chihuahua, and afterwards a muleback trip from Ojito, the then western terminus of the Parral & Durango Railroad, westward across the Sierra Madres to Guadaloupe y Calvo, Boborigame, Cebollitos, Mala Noche, Cerro Colorado and La Cumbre, in the southwestern corner of the same State, where it adjoins Sinaloa and Durango, and back again eastward, recrossing the Cordilleras to Ojito. This muleback trip occupied twenty-nine days, and, while the distance traveled was not so very great horizontally, probably less than 400 miles, my traveling companions and I were in the saddle at least a portion of twenty-seven out of the twenty-nine days.

Mining Scenes in Mexico.

A party traveling in the mountains of Mexico must be "self-contained,"—that is, it must carry everything that is needed for sustenance, comfort, health and safety. In our party were three Americans beside myself, one of whom was familiar with the country and spoke Spanish—a most valuable acquisition in that country. We outfitted partly in Los Angeles, Cal., and partly in Parral. In Los Angeles we bought a small 9-foot centerpole tent, the centerpole in two sections, for convenience in packing; light folding military cots and blankets. In Parral we obtained mules for riding and packing; such provisions as flour, beans, bacon, fresh meat, lard, coffee and sugar, and frying pan, coffee pots, tin plates, cups, spoons, knives, forks, etc. We also hired three "mosos," or native servants. Upon the kind of mosos that one gets much depends for the comfort and pleasure of the trip. The moso's work is to care for the mules—to feed, pack and unpack them, and drive the pack animals, prepare the camp at night, cook the meals, wash the dishes, and be good natured and respectful. Our party was fairly fortunate in this regard. We took one moso (Santiago) the round trip, and picked up two others at Guadaloupe y Calvo in place of two worthless ones that we started out with. These mosos will trot behind the pack mules all day long, with nothing on their feet but boraches—a piece of leather like a sandal, held to the sole of the foot by leather thongs passed around the ankles. Frequently they must cross streams and travel through mud, and in the high mountains we encountered some ice and snow; but the good nature of the mosos was rarely disturbed, and they would often come into camp at night after the day's journey whistling or singing. At night, if they have a good camp fire, a manta to lie on and a serape to wrap up in, they will sleep soundly until the hour for hunting up the mules in the morning—usually 3 or 4 o'clock—and apparently want nothing better. Their compensation is $1 a day (Mexican)—about 40 cents of our money—and "found." This moderate figure enables one to indulge in personal service that would be extravagant at home. The mules, with their packs of supplies for the trip, camp outfit, etc., were sent out from Parral a day or two ahead, and were met at the end of the railroad, at Ojito, the last station on the road, a few kilometers from its terminus in the timber. The start from Parral was made at 6 o'clock in the morning and Ojito was reached about 10 o'clock. It was expected that a ride of three or four hours would be made the first day, just to get accustomed to the trail. So, after the arrival at Ojito, the packs were made up for the mules and the first meal in camp prepared and served. Although the sky was clear, our first meal was prepared and eaten in a high gale of cold wind, most unlike one's first conceptions of Mexican weather. For a table a manta, or mat, or a piece of canvas spread on the ground, and, with a good open-air appetite, a meal of frijoles and bacon, or, perhaps, a little fresh meat and good biscuit, baked on an ingenious device of tin for catching and reflecting the heat from the camp fire upon the baking bread, is by no means bad.

The station of Ojito is south and a little west of Parral and but a few miles from the boundary line of Chihuahua and Durango. The course traveled from Ojito to Guadaloupe y Calvo is about southwest, and the distance is probably a little more than 100 miles. Distances, however, in that country are popularly measured by time, rather than by miles, and an inquiry as to how far it is to a certain point will be answered: "It is 3½ hours," or "two hours," as the case may be. This takes into account the difficulties or steepness of the trails, which are frequently more important than the number of miles. But I observed that it always required the full amount of time claimed to make a given point, and when I was told that it was a ride of "3 hours and 35 minutes" to Cebollitos, or wherever it was, I generally calculated on about five hours of stiff travel, and was rarely disappointed by an earlier arrival at the destination. The trip from Ojito to Guadloupe y Calvo is considered 3½ days' muleback travel, and it can be made in that time; but 4½ days is more comfortable.

Between the two points the much-traveled trail passes through a great variety of country and scenery. It passes over mountains and through valleys, but, while thus alternating in elevation, it gradually rises from 5000 or 6000 feet above sea level on the eastern slope of the Sierra Madres until the continental divide is crossed the second day out at an elevation of 10,500 feet. The point of division is not sharply marked; but, on the contrary, there are miles of comparatively level country at the summit, covered with pine and oak timber with a good growth of grass in the abundant soil underneath. There are occasional small mountain lakes, and altogether the resemblance to the timbered parts of our own Sierra Nevadas in California, in the character of the timber and general appearance of the country, is quite marked, though the timber is not so large nor are the trees so near each other as in our mountains.

The scenery is often grand. Four rivers were crossed, and some of these cut the mountains with deep canyons which would be notable if they were in the United States. One of these, the Rio Verde, compares favorably as to impressive grandeur with the Grand Canyon of the Yellowstone, although it lacks the brilliant and varlegated coloring of the latter, its precipitous walls, as its name implies, being a deep shade of green. The trail crosses this canyon, passing down to the bottom, from the comparatively level tablelands on one side to the same on the other. A half day is needed to cross the canyon, although the horizontal distance across can be scarcely more than 3 miles. It is a piece of the trail that is most trying to both mules and riders.

Of the four rivers that were crossed, one, the Reparo, flows northeasterly into the Concho, which finds its outlet in the Rio Grande, and thence into the Gulf of Mexico. The other three flow westward and have their outlet in the Pacific. They are the Rio Verde and the Turache, which flow into the Rio Fuerte, and the Bozanopa, which is one of the branches of the Sinaloa river. The latter river was crossed two days west of Guadaloupe y Calvo.

After leaving the rich mineral districts of Parral, Minas Nuevas and Santa Barbara, the entire country westward nearly to Guadaloupe y Calvo is covered with light-colored, eruptive rhyolite rock, locally called cantara, in which little or no mineral of value is found. At Guadaloupe y Calvo the cantara has been eroded away so that the underlying rocks are exposed in which the veins exist, and to the westward of Guadaloupe y Calvo, although still somewhat in evidence in places, the cantara has been worn out over large areas, exposing the older formations and their inclosed mineral veins. East of the Sierra Madres, while gold veins are occasionally found, silver prevails, and on the western slope the reverse condition exists, gold veins predominating. This is especially true in the western part of the Guadaloupe y Calvo district.

Because of the rhyolitic overflow referred to over the higher parts of the Sierra Madres, covering as it does to a great depth such possible veins as may exist in the lower formations, the trip has not the economic interest that it would posses were it a region traversed by mineral veins. But the scenery is grand and the trail for long distances passes through forests of pine, oak and madrona. There are no towns or hamlets between Ojito and Guadaloupe y Calvo. About five hours out from Ojito is a ranch at the Rio Reparo. Midway between these points is a small stream, called Chivete, and a spring in the Navarro valley, an hour farther along. Three and a half hours west of Reparo is the Arroyo del Mais, pretty well up in the main Sierras. This was our second camping place, on the night of January 21, and, as the ice froze an inch thick during the night, it may be inferred that it was a cold camp. As no one lives within miles of this desolate arroyo, and no corn or other cereal is raised there, there appears no particular reason why it should be called the arroyo of corn. From Arroyo del Mais to Rancho de las Lagunas is about three hours and a good ride for lunch. Here are the ruins of an old adobe ranch house and corral. From the Lagunas to the bottom of the Rio Verde canyon is three hours more. The clambsr down this canyon and up again on the western side, embracing a drop and raise of from 1700 to 2000 feet, is something to remember. A stream of hot water flows into the Rio Verde near the ford, carrying a good volume of water. Its source is a series of hot springs a mile or so above. From Rio Verde to Cuevo del Burro is three hours' ride. We were caught in a storm of rain and snow at this camp for a day on our way out. From Cuevo del Burro to Cienega Prieta is another three hours, and here we camped the fourth night out. The Cienega Prieta is the first "going" ranch beyond the Reparo and is conducted by an American, Mr. Rhodes. A supper and breakfast, that included eggs and fried chicken, was a welcome change from the ordinary camp fare. From Cienega Prieta to Guadaloupe y Calvo the ride is made in one day, the Turache river and canyon being reached about two hours out, Ojo Frio in six hours and Guadaloupe y Calvo in eight hours. The riding time from the railroad is considered twenty-eight to thirty hours. While there are many grander places in the world than Guadaloupe y Calvo, after this ride there are few that are more welcome to the arriving traveler.

Guadaloupe y Calvo is the capital of the mining district of that name. Here all mining locations, or denouncements, must be made and recorded. Here, also, is a postoffice and a telegraph office combined, the telegraph line being owned and conducted by the Mexican Government. One of the wise policies of President Diaz is to run telegraph lines into the re-

mote sections of Mexico, enahling the rapid transmission of news. This makes revolutions difficult and almost impossible. The rates for telegraphing are reasonahle and can hardly he sufficient to fully indemnify the Government for maintaining and operating the lines. When a message is received and paid for, the operator issues to the sender an official receipt for the money paid. At the postoffices, upon receipt of the mail, a list is made of persons for whom there are letters and the list is posted in the office. So there is no necessity to inquire for mail. This system would hardly do in a large American office, where thousands of letters are received each day. The officers of the postal department—the Administracion de Correos—are usually polite and accommodating. In Guadaloupe y Calvo the principal official is the Jefe Politico. His powers are very great and include to some extent those of hoth an executive and a judicial character. With evil-doers of a desperate type the Jefe Politico does not hesitate to exercise the power of life and death. The present Jefe Politico at Guadaloupe y Calvo, Don Angel P. Ariza, is a man of education and good judgment, and has the reputation of administering his office with courage and justice. In two years of his incumbency twelve men had either heen executed in the district or killed by the rurales while in pursuit for crimes of pillage or violence.

When an individual or a hand of men are known to he criminals they are treated with very little ceremony. The rurales follow them up, hut rarely capture them. A mound of rock along the trail, surmounted hy a rude cross, is the sole reminder of their existence. Ahout two days' travel northwest of Guadaloupe y Calvo, and an hour before reaching Bohorigame, we came upon a mound in the forest—a very large one. It was ahout 20 feet long, 10 feet wide at the hase and 5 feet high. A neat cross marked the head. In this pile of rock thirteen handits were huried—an entire hand, who twelve or fifteen years ago infested this section, killing and rohhing travelers on the trail. The rurales surrounded and killed every one of them, then huried them in this decent way and placed a neat cross at the head of their tomb for the repose of their souls. So rigorous are the Mexican officials in dealing with this class of criminals that it is douhtful if there is an organized hand of bandits in Mexico. Certainly there is not in this section. The crimes of murder and rohhery on the trail or highway are rare. Nevertheless, every one travels armed, although the necessity does not seem apparent. It is, however, the custom of the country, and possihly one would receive less consideration and not be so safe if he traveled unarmed.

Guadaloupe y Calvo is a town of 2000 or 3000 people, and thoroughly Mexican in its architecture and characteristics. One of the accompanying illustrations is a street scene in Guadaloupe y Calvo. The houses are generally of adobe and one story in height The streets are very narrow and paved with cobblestones No vehicles ever pass through them, as all the traffic is done on pack animals. The principal store, that of Don Tiburcio Garcia, is a fine building of two stories, which also includes his well-furnished residence. A large stock of merchandise is carried, embracing ahout everything that is likely to be needed in the country Don Tiburcio has also built a two-story hotel—the Hotel Mina—in anticipation of a considerable American and European patronage; hut thus far there have not heen a sufficient number of patrons to justify its being kept open. The town was built hetween 1835 and 1840 as a result of the leasing hy an English company of the Rosario mine, which was discovered in 1835. It was constructed on the hacienda of the English company for the accommodation of its employes. The company also obtained a concession from the Mexican Government to erect a mint to coin the production of the mine. This mint has not been in operation since 1848, hut its massive walls are still for the most part intact. (See illustration.) The English company had a cannon as part of their equipment and mounted it so that the main streets of Guadaloupe y Calvo could he raked with grape and cannister at any time. This was during revolutionary times; hut it is said that during the occupancy of the English company Guadaloupe y Calvo was always a quiet and peaceable town. The Rosario, which is a gold mine, has heen worked in a small way only during the past fifty years. It is reported to have been sold recently to a son of W. A. Clark of Montana. The only other mine of importance at Guadaloupe y Calvo is the Independencia, helonging to Don Tiburcio Garcia, which runs intermittently.

California at the St. Louis Exposition.

In view of the desirahility of making a representative exhibit of the resources of California at the St. Louis Exposition, L. E. Auhury, State Mineralogist of that State, has appointed collectors, who are now at work securing specimens of ores, minerals and rocks for this exhihit. It is the intention to in this manner secure an exhihit of that State's mineral resources which will be a duplicate of that now on exhibition at the State Mining Bureau in San Francisco, and to use this new collection for exhibition purposes hereafter, together with such additions as may he made when occasion requires.

Velocity of Objects Floating in Water.

Discussing the velocity of water flowing in streams and the relative velocity of objects floating in or on the water, G. H. Gihson in the Electrical Review says in part as follows:

Starting with the river hed, which for the sake of simplicity we will treat as a rough hut uniformly inclined plane, water, or anything that is placed upon it, will move downward with increasing velocity until the frictional resistance to motion is equal to the component of the earth's attraction parallel with the surface of the plane. If this first hody of water he treated as a continually running sheet, and a second sheet he superposed on the first sheet, the second sheet will reach a final velocity higher than that of the first, hecause it is sliding upon a surface itself in motion and offering less frictional resistance.

This argument may he continued until we have any supposable depth of water.

If, now, an object he placed upon the stream, we might suppose it to act like a superposed sheet of water. However, if it projects into the water to any depth, as a solid floating ohject would do, the upper parts would be in contact with water moving with greater velocity than the water helow. The deeper water will naturally retard its tendency to float as fast as, or faster than, the water near the surface, and it will have an intermediate velocity.

It might he possihle for a very thin floating object —as a hoard, for instance—to float as fast or nearly as fast as the surface water, and considerahly faster than the water at a depth. On the other hand, since the water at a depth would move more slowly than the surface water, it would retard deep floating bodies, and hodies of different shapes would have slightly different velocities.

It is known to hydraulic engineers that the velocity of water in a stream increases with the distance from the hed and banks. It is impossible to conceive how a floating hody, since it must have depth, could float faster than the very surface of the water, which is in no way tied to the water helow it.

Transportation in Peru.

In the high Andes mountains of Peru the development of mines hy modern equipment and methods is much retarded by lack of transportation facilities. In Peru, the land of the Incas, who huilt up and ruled one of the most extensive empires known to the world's history, the roads as constructed and maintained hy them are described by the Spaniards, their conquerors, under Pizarro, early in the sixteenth century, as heing wonderful pieces of engineering work. These splendid highways during the succeeding 400 years have received little or no attention,

Heavy Mortar on Steel Wagon for Transportation in Peru, S. A.

and the result is that the roads leading to the mines are not always in first-class condition, or, in fact, much hetter than roads in the mining regions of the United States, if as good. The Chuquistamho mines of Peru were described herein May 30, 1903, accompanied hy several views of the village, mill, mine, etc. The accompanying engraving shows the method hy which the heavy mortars of the mill were transported into the mountains. The vehicle upon which the mortar rides is of steel and was constructed for this purpose. The mill of the Chuquistamho mine is helieved to he at the highest altitude of any gold mill in the world—that is, a mill not huilt of sectional machinery. It is situated at an altitude of 12,000 feet ahove sea level, the greater portion of the timber and machinery used in its construction having heen to an altitude of 15,655 feet in transit from the coast.

Use of Alkalies in the Cyanide Process.

Written for the MINING AND SCIENTIFIC PRESS by ERNEST G. SWEETLAND.

There is no doubt that the use of certain alkalies in proper amounts, as a neutralizing agent to overcome the destructive effects of the acid which is usually present in tailings, is a very important factor in the successful application of the cyanide process.

The alkalies usually employed for this purpose are lime, or the hydroxide of potassium or sodium.

The amount necessary to add to the tailings to produce the most economical working results is usually determined in the lahoratory by one of two methods:

The first is to extract the acid from a weighed quantity of ore with water and titrate with a $\frac{N}{10}$ solution of potassium or sodium hydroxide, and from the results ohtained calculate the amount necessary per ton of ore.

The second is to determine what amount of alkali will he most effective by making several trials in the laboratory, using a different amount of alkali in each case.

I do not think the first method is to be preferred, as in many cases an amount of alkali in excess of that which is necessary to neutralize the acidity of the ore will effect a practical saving of cyanide, and the amount in excess which produces the hest results can hest be determined hy the second method. However, I think the results indicated by the second method are in general higher than is practical on a mill scale if the tests are made with a new cyanide solution, and if these results were strictly adhered to in the mill the protective alkalinity would soon hecome excessive.

This would suggest using mill solution for the test rather than a solution which had never heen used, and in that case I think the results would he still more reliahle than hy either of the other methods.

In this connection the effect of the alkali on the zinc of the precipitation boxes should he considered, as the consumption of zinc in the mill will depend greatly on the alkalinity of the solution.

As to whether the hest results are ohtained hy using the alkali in the form of a wash previous to cyanide treatment, or hy adding it to the ore as it enters the vats can best he determined hy experiment in each individual case. When the percolation process is employed it is not always practicable to use a preliminary wash on account of the extra time which is consumed hy so doing; particularly if the ore is of a slimy character; hut as a rule less cyanide is consumed when this method is practiced.

In considering the merits of the different alkalies as neuralizing agents we find that in general, when the ore is not of a refractory nature, lime is the most economical; hut in certain cases where the solution has a tendency to become fouled by solution of soluhle salts of iron and alumina from the tailings, and zinc from the precipitation boxes, the hydroxide of potassium or sodium possess certain regenerative properties which should not he lost sight of.

To prove this I took a sample of a mill solution which was fouled with zinc, iron, alumina and copper, which tested .035% of free cyanide. Upon the addition of a small amount of KOH a gelatinous precipitate of the hydroxide of these metals was formed, which upon analysis proved to he principally zinc, hut also contained appreciahle quantities of iron, alumina and copper; and the solution after the removal of the precipitate tested .09% of free cyanide. This is a regeneration of .055% KCy or 1.1 pound of potassium cyanide recovered for each ton of solution treated. The reaction which took place, considering only the zinc, I think was as follows:

$$ZnCy_2KCy+2KOH=3KCy+Zn(OH)_2.$$

This suggests a method hy which fouled mill solutions might he put in a better working condition hy either adding the alkali to the sumps and collecting the precipitate hy means of a filter press, or by adding it to the solution hefore it enters the vat and allowing it to he deposited on the tailings in the vats to be discharged with the residues later. In that case it should he added as near the end of treatment as possible so as to give it the least chance to he redissolved. In general the sooner the precipitate is removed from the solution the hetter, as at least

some of the metals precipitated would be re-dissolved by continued contact with the solution.

The weaker the solution the more marked would be the success of this method.

Possibly where lime is used and the solution has a tendency to become fouled the best working results could be obtained by occasionally using caustic potash or soda for a short period instead of lime.

As the use of the correct amount of the proper neutralizing agent is not only of prime importance in keeping the cyanide consumption at a minimum, but is also an important factor to the successful precipitation of the metals in the zinc boxes, too much care cannot be exercised in keeping the alkalinity of the solution properly adjusted.

Mining in Broken Hill, New South Wales.*

NUMBER II.

Written by EDWIN K. BEAUMONT.

The term underground open-cut system may at first seem erroneous or misleading, as the term open cut is generally applied to excavations from the surface

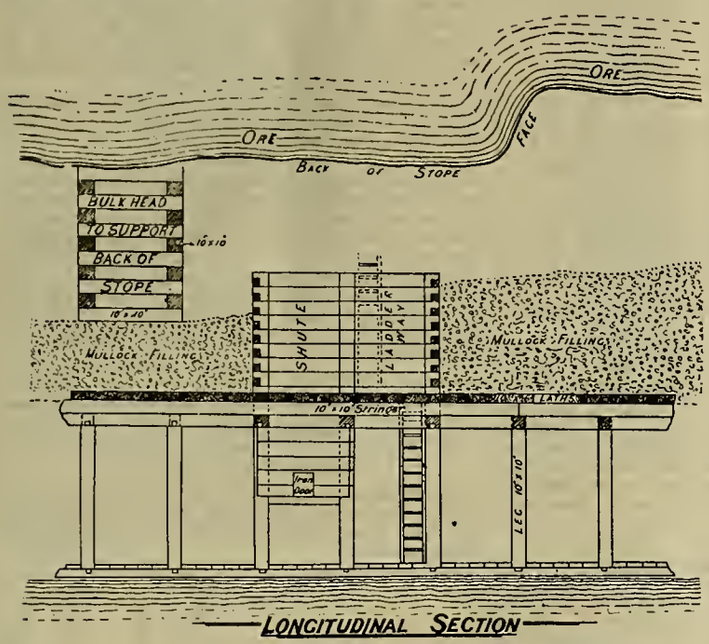

Fig. 4—The Underground Open Cut System.

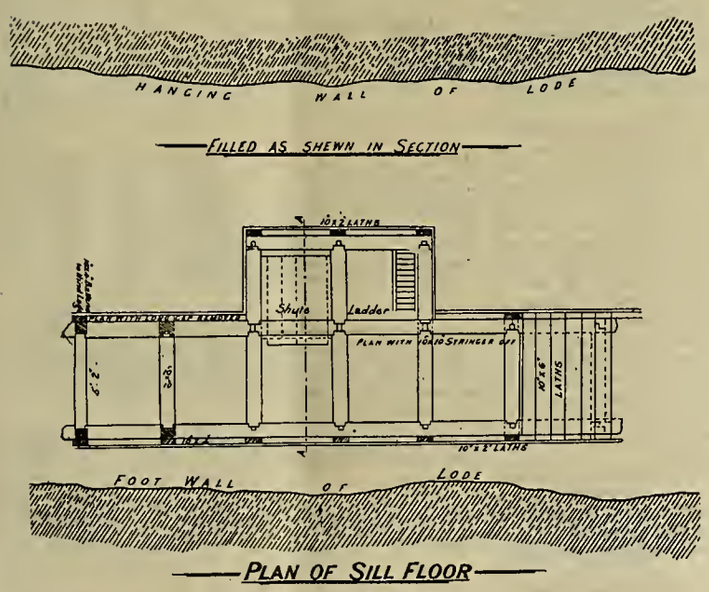

Fig. 6.

downwards, but the above name is that generally given by the miners to the large stopes which are worked under this system. A comparison of Figs. 4, 5 and 6 with Fig. 3 shows the great difference. The drives are first run along the foot and hanging walls, and then through the ore body. From the upper levels winzes are sunk and crosscuts driven at convenient intervals. The winzes serve several important purposes. They ensure a complete and lasting ventilation to the stopes during their upward way by carrying off all noxious gases as they form on the lower workings or are given off by the sulphide ore, and thus enable the miners to work with a greater degree of comfort, and also to do a fair shift's work, which could hardly be expected in a hot stope with a constant atmosphere of about 90°. The winzes serve as passes or chutes through which the filling is conveyed from the upper levels, and, by a succession of chutes and winzes from the surface, is deposited where desired. This system is successful in the Central mine, for the mullock or waste is broken in a large open cut on the surface and is conveyed in side-tipping trucks of capacity of one cubic yard, drawn by horses through a tunnel, then discharged into a chute, from which, by a series of winzes, chutes, etc., it is distributed throughout the mine where required. The winze is used as a starting place or face from which to work the stope, and, after the ore is extracted, say, the first 10 or 20 feet, it is timbered up closely into two compartments, as shown in Fig. 4. One compartment serves as a chute or pass for the ore to the sill floor, as the stope works upwards, and the other compartment as a ladderway and means of ingress and exit for the miners and others to the upper workings of the stope. The sides of the initial drives on the sill floor are extended to the desired width along the lode, and thus the stope is formed on the sill floor, the sill timbers placed in position and then filled up. On top of these timbers the bedding for the filling is placed, as shown in the section, Fig. 5, being 10x10-inch and 10x3-inch timbers, arranged to carry the burden. Above these "sollars," as they are called, the only timbering is that of the chute and ladderway, all other spaces being filled in with mullock from wall to wall, as indicated, which is placed in layers of 7 feet to 12 feet. As the broken ore falls and the traffic also is all the on mullock filling, each succeeding layer gets well rammed and solidifies before the next one is placed on it. In the large open stopes in the Central mine almost all the boring is done by machine drills driven by compressed air. These bring down the ore in large pieces, frequently from 7 feet to 8 feet by about 2 feet wide. These pieces are then bored by hammer and drill and popped into smaller sizes, then spawled into sizes—generally less than 1 foot long—for throwing down the chutes and removal in the trucks, which are all end-tipping and hold about 1600 pounds of broken ore. When the "back" or top portion of the stope is "heavy," or seems dangerous and likely to come away, bulkheads are built under it. These consist of 10x10-inch timbers placed at right angles to each other, one above the other and tightly wedged. (See Fig. 4.) When bulkheads are built on the mullock filling, a bed of 10x4-inch sollars is first laid on the mullock to distribute the pressure over as large area as possible; then the first 10x10-inch timbers forming the bulkhead are laid transversely across the sollars. These timbers are afterwards removed, the burden shot down and the same timbers used over and over again.

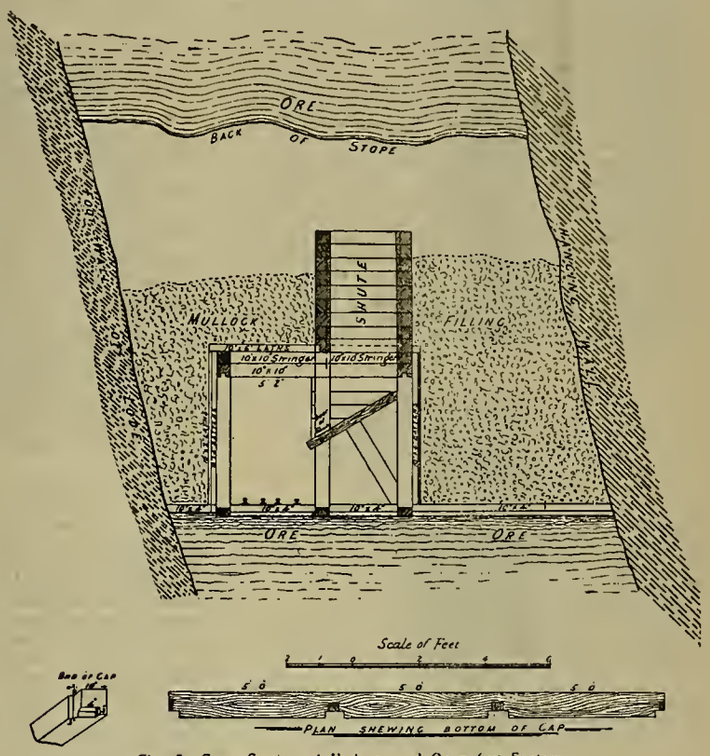

Fig 5—Cross Section of Underground Open Cut System

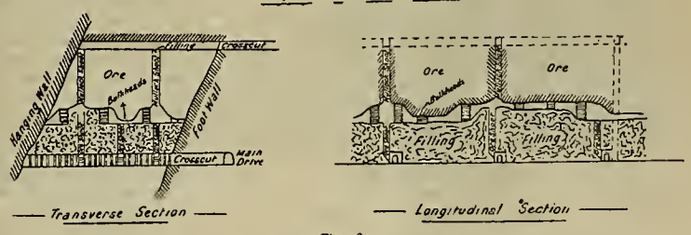
Fig. 7.

— Stoping in Horizontal Layers —
— Adopted in Hard Ground —



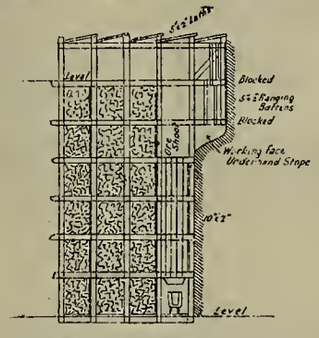


Fig. 8.

SLOPING STOPE SYSTEM.—A somewhat similar modification of the same system, called the "sloping stope system," is shown in Figs. 7, 8 and 9. This method is extensively used on the Broken Hill Proprietary mine, and I am indebted to E. J. Horwood, C. E., mining manager, for permission to copy his drawings showing this system. In many instances the same description will apply as in the foregoing notes on underground open-cut stoping, viz., the levels on the sill floors are first formed, taking notice that the width of the stope depends on the nature of the ore

*Trans. Aus. Inst. Min. Eng. (condensed).

to be mined, or its ability to support itself by leaving the back in the form of an arch; the whole stope when formed is somewhat in shape like an isosceles triangle, of which the level or sill floor forms the base and the winze the apex; also, the winze (as before) is sunk from the level above, and the stope is started from the winze, as in the other open-cut system, while the winze serves the same purpose for ventilating and as a pass for the mullock filling into the stope, also chute for the ore to the sill floor. The great difference is that the stope slopes laterally to each side, instead of going up with a level or even floor, and as these sides rise with the stope, provision must be made for preventing the mullock filling from running into the adjoining stope when it rises; this is done by placing vertically at the sides of the stope, about 5 feet apart, 10x4-inch stringers, which overlap at the ends, and are then covered with 10x2-inch planks placed horizontally against the face of the ore. These may be removed and used over and over again. When the adjoining stope is afterwards being worked, the stoping advances forward from 5 to 8 feet at a time, and from 8 to 12 feet upwards. The advantage of these sloping sides is that the broken ore falls on 10x4-inch sollar boards placed on the incline plane of the mullock, and thus rolls to the chutes at the sides without further handling, excepting, of course, the large pieces, which require hand boring, popping and spawling, as before mentioned. It will be noticed on referring to Fig. 7 that the stope is filled in with mullock to within 2 or 3 feet of the back, and the stope is always worked downwards, starting from the winze; but, if the back is heavy or faulty, it is secured by 10x10-inch legs resting on the sollars (or on bed logs left in the mullock), or at right angles to the sollars and also to the back, as they are nearly parallel; these are tightly wedged and blocked and only re-

Section of Stope on the Square Set System.

Fig. 9.

moved as the ground is taken out. When the stope is about 9 feet high the sollars are taken up and stored aside for further use. The stope is mullocked up again to within 2 or 3 feet of the back, when the chutes are again built up a proportional height and the sollars replaced on the mullock, the sloping process, as before, taking another slice from the back, also starting from the winze downwards. The Broken Hill Proprietary Co. has of late years been adopting a modification of the square set system in working these "sloping ores" by timbering up the middle of the stopes with square sets, which are filled with mullock as the work proceeds; but as the back—or working face in this instance—is sloping as in the last mentioned method, each successive floor of sets stands back one or in such manner that the outside faces of the sets follow as nearly as possible the same angle of inclination or inclined plane as the face of the ore body.

In this way the miners are always within a safe distance of working and examining the face and back of the workings, and all the favorable points of the other adaptation of the sloping stope system apply to this system, with the advantage that the miners have a good footing on the set timbers, and the great convenience offered for the despatch of the ore through the chutes constructed in the square sets.

(TO BE CONTINUED.)

Values in Sluice Concentrates.

J. B. Hobson, manager of the Consolidated Cariboo Hydraulic Mines at Bullion, writes in the Mining Record: "I send you herewith copy of analysis of a sample of heavy sand, sulphurets and other concentrates obtained after cleaning up the sluices at the Consolidated Cariboo hydraulic mine. Having made qualitative tests before sending the sample to the assayer, I found indications of the presence of palladium. I do not remember of having noted any report of the presence of palladium in any of the assays of concentrates from the auriferous alluvials of British Columbia; and it might be well for those operating alluvial mines to have their concentrates carefully examined for the presence of this metal—which belongs to the 'platinum-osmium-iridium' group and possesses a commercial value higher than that of platinum."

COMMERCIAL VALUE OF SLUICE CONCENTRATES.

Metal.	Ounces Per Ton of 2000 Lbs.	Value Per Ounce.	Value Per Ton.
Gold	147.51	$17.00	$2,507.67
Silver	138.34	.50	69.17
Palladium	46.55	19.00	884.45
Platinum	15.12	16.25	245.70
Osmiridium	4.73	29.00	137.17
Copper, 14.30% (wet), 10c. per pound.			28.60
Total value per ton			$3,872.76

Leaching Siliceous Copper Ores With Acids as Solvents.

It is only within the last few years that the discovery of large deposits of comparatively low-grade siliceous copper ores has occurred in suitable quantities to warrant the erection of plants for working same. In some cases the distance of these deposits from an easily accessible source of flux supply, and in others the low grade of ore, has led to many experiments for the purpose of extracting values by leaching with sulphuric acid.

The process, as a commercial proposition, is in its infancy. Numerous patented processes for leaching copper ores with varied mechanical devices for the utilization of sulphurous acid and sulphuric acid have been presented. The former of these two acids has been the more extensively used, but owing to the large consumption of iron in the process of precipitation, after treatment, and also owing to the difficulty in obtaining a thorough washing of the pulps to free them from the weak acid solutions, and the loss of acid necessarily occasioned thereby, these experiments have not heretofore been thoroughly successful.

The use of sulphurous acid obtained from the combustion of pyrite is theoretically much cheaper, owing to its readily solvent qualities upon the metal, and the cheaper methods of precipitation that can be used. But, heretofore, no readily and commercially usable device has been devised for the employment of this extremely volatile acid. That is to say, many schemes have been placed before the public for the utilization of the latter, but none of them have proven such a commercial success as to warrant their extensive use.

The value of any chemical oxidizing agent in conjunction with a dissolving acid on ores containing a low percentage of sulphur is somewhat problematical, as it may be a question whether the use of potassium permanganate, or other oxidizing agents, have been really effectual in their action.

In any case, the practical outcome of all experiments so far seems to have demonstrated the fact that the attainment of an oxide from a low-grade sulphuretic copper ore by means of any chemical oxidizing agent, is more or less hypothetical, and what would in one case be suitable to one ore, would be absolutely ineffectual on another.

The field for the practical and commercial exploitation of the process seems to be narrowed down to the following: The pulverization of the ore to 30 or 40 mesh. The classification of the pulp into two grades, namely "coarse" and "slimes." The direct leaching of the "coarse" in percolation vats under lengthy periods of contact, and the draining of the solutions from the vats by natural gravitation. The treatment of "slimes" by some method of forced filtration, whereby the solvents are passed through the pulp in such a manner as to obtain a thorough permeation of the whole of the bulk. The separation and washing of the solutions from the pulps so as to obtain a thorough extraction and a precipitation of values therefrom by means of iron or lime.

The latter method of precipitation is at present only used in the districts where limestone occurs with or near the copper deposits.

The extraction of values from cyanide potassium solutions containing gold and silver values by means of filter presses is familiar, and a somewhat similar method is advocated in the extraction of values and the washing of the acids from the slimes in the treatment of copper ores.

Taking the following as the method employed for the preliminary application of the solvents and the pulps: The classification of "coarse" from "slimes." The treatment of slimes in circular cone-bottomed vats, wherein an agitation of the pulps is obtained by means of pump circulation in which the mass is taken from the bottom of the vat and constantly circulated again at the top in the presence of the solvent. The separation of the solvents from the pulps and the washing of the latter free from all trace of the solvent by natural subsidence or gravitation or by filtration.

There is at present no means of efficiently displacing the whole of the solvent used in the extraction of values from any ores by any of the known methods of gravitation or natural subsidence. The only efficient method for so doing is by an urged or forced method of filtration. That is to say, any process of displacement by wash waters, of the solvent contained in a mass of pulp non-homogeneous in character, and possessing little uniformity or compactness, such as takes place in the open vat, is practically impossible, owing to the non-uniformity, unpermeability and non-homogeneity of the pulps.

The filter press method of extraction as applied to gold ores is equally applicable to the extraction of solvents from copper ores, and the method recommended is as follows:

After the application of the solvent to the slimes, and when a thorough dissolution of values is obtained, there is in the vat a certain portion of solids containing little or no values that were heretofore component parts of the solids.

The whole of this pulp may now be forced or gravitated into a pressure tank and thence into the filter press. Seventy-five per cent of the solutions are extracted in the process of filling the press, leaving 25% in the cakes.

Charges of wash water are then passed through the cakes, which will come out at the common eflux valve or from the separate valve on each filter frame, and this process may be continued until the liquids coming from the press show no sign of acid.

The solutions are passed direct to the precipitation vats. By this means the whole of the solvents containing values are extracted from the pulps and taken direct to the precipitation tanks and the solvents thence taken to the percolation vats, made up to requisite strength and reused.

The filter press, as constructed by the American Filter Press Extraction Co., of Denver, Colo., is of iron throughout, with the exception of the valves, which are of copper. The iron frames and plates, which come in contact with the acid, are coated with asphaltum, applied hot and burnt in. The channels for the conveyance of the pulps, and subject to friction, are lined with lead, and the machine throughout devised to withstand the chemical erosion, etc., that is inseparable from the use of strong acids.

The pressure tank (or monteju) should be constructed of iron (lead lined), copper or wood. The latter method is preferable, with a lead-lined iron hopper bottom.

Cost of Mining and Reducing Ores, New York & Nevada Copper Co., Ely, Nev.*

Compiled by S. W. TRAYLOR.

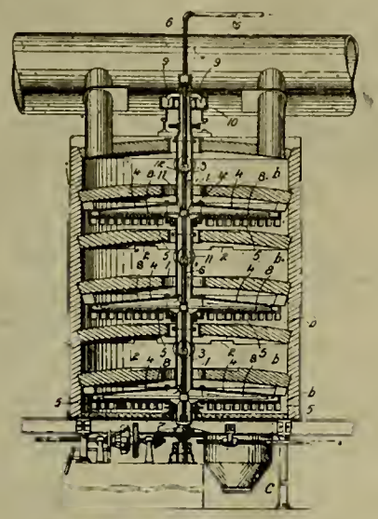
The following estimate on cost of mining and reduction of the ores of the New York & Nevada Copper Co. refers particularly to cost of smelting in blast furnaces:

CONCENTRATING ORE.	Tons of Ore.	Cost per Ton of Ore.	Cost per 1000 Tons.	Cost Producing and Marketing 1 lb. Refined Copper.
				Cts.
Mining	1,000	$1.00	$1,000	2.12
Transportation	1,000	.125	125	.26
Concentration	1,000	.300	300	.63
Smelting	1,000	.360	360	.76
Converting	1,000	.258	258	.55
Refining	1,000	.355	355	.75
Freight and commission	1,000	.496	496	1.05
Depreciation and managem't.	1,000	.200	200	.42
	1,000	$3.094	$3,094	6.54

In smelting the concentrate product an additional loss of 5% is figured, which would show the net amount of copper accruing from the 1000 tons of concentrating ore to be:

47,310 pounds, at 13 cents per pound	$6,150 30
Less cost of production	3,094 00

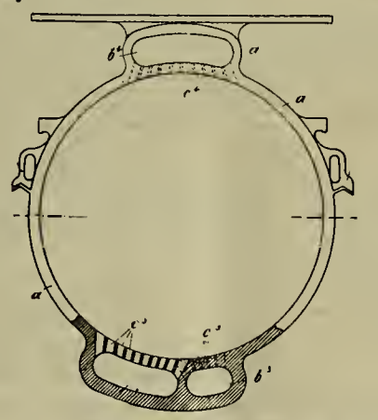
SMELTING ORE.	Tons of Ore.	Cost per Ton of Ore.	Cost per 600 Tons.	Cost Producing and Marketing 1 lb. Refined Copper.
				Cts.
Mining	600	$0.750	$ 450.00	1.17
Transportation	600	.125	75.00	.19
Smelting	600	2.500	1,600.00	3.90
Converting	600	.258	154.70	.40
Refining	600	.355	213.00	.55
Freight and Commission	600	.496	297.60	.77
Depreciat'n and managem't.	600	.150	90.00	.24
	600	$4.634	$2,780.20	7.22



*Condensed.

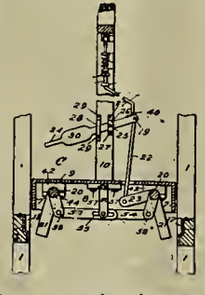
Mining and Metallurgical Patents.

PATENTS ISSUED JULY 14, 1903.



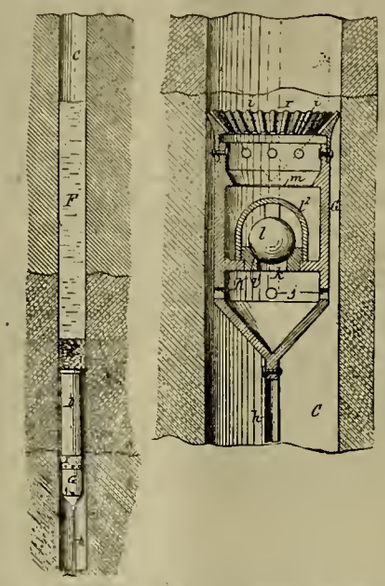
Specially Reported and Illustrated for the MINING AND SCIENTIFIC PRESS.

ROASTING FURNACE.—No. 733,658; F. Klepetko, New York, N. Y.



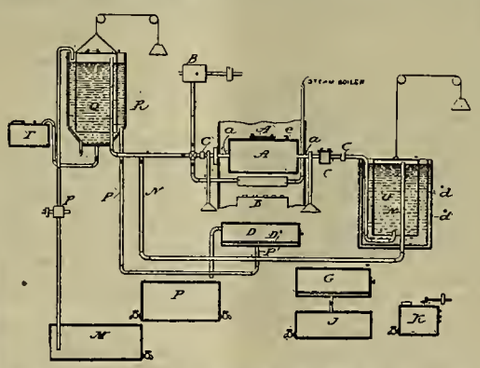
In furnace having plurality hearths, rotatable hollow shaft passing through hearths, series hollow arms radiating from shaft, and extending into several hearths, inner stationary water-feed pipe located within shaft, series distributing pipes located within and communicating with interior hollow arms freely rotating therewith about feed pipe, latter discharging water through peripheral walls into inner ends of distributing pipes, whereby same is caused to circulate through arms and hollow shaft to point adjacent to feed end of feed pipe.

FILTERING PRESS.—No. 733,663; V. Lapp, Leipzig, Germany.



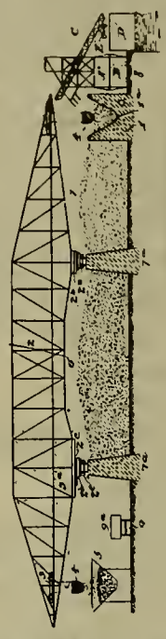
In filtering press, combination with set of trays, another set of trays, trays of one set alternating with those of other, and filtering cloths located between various trays, each tray having sloping lower portion, upper elongation forming portion of channel, and lower elongation forming portion of two channels; trays of one set communicating with upper channel and at bottom with one of lower ones, trays of other set communicating at bottoms with other of lower channels.

SAFETY CHAIR FOR MINING CAGES.—No. 733,907; H. Hanson, Los Angeles, Cal., and F. L. Dwight, Bisbee, Ariz.



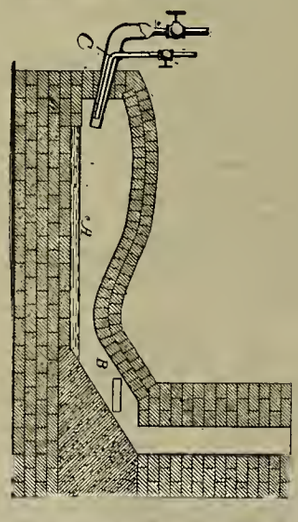
In safety devices operating between shafts mines and buildings, cages provided with hangers having guides on outer faces, guide posts, cable for suspending cage, hand lever pivoted to one of hangers, pitman-rod pivoted one end hand-lever and opposite end to crank arm, cage provided with platform having slots in rear end thereof, oscillating rods journaled within downward perforated lateral flanges of platform, oscillating rods carrying legs fastened thereto, one leg projecting upward through one slot in platform, connecting-rod pivotally connected at end thereof to upwardly projecting end of leg, opposite end connecting-rod pivotally connected near lower end of one of front legs, whereby all legs simultaneously thrown in contact with frame and cage caused rest temporarily at predetermined station.

PARTITION PLUG FOR OIL WELLS.—No. 733,492; C. S. Little, Montpelier, Ind.



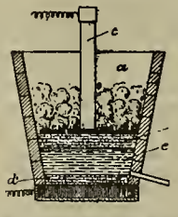
Device isolating different portions of oil well from each other consisting of partition plug adapted to bear against wall of well and provided with anchor or support for sustaining same at proper height in well.

PROCESS OF EXTRACTING PREOIOUS METALS FROM THEIR ORES.—No. 733,859; J. W. Maxwell and J. W. Sawyer, Louisville, Ky.



In process of extracting precious metals and other values from ores, extracting metalloids; removing them from ore and ore treating receptacle; by treating powdered ore with heat, chloride of sodium, oxygen, nascent chlorine, current of chlorine gas; volatilizing metalloids; carrying volatilized metalloids, and metalloid compounds and metallic chlorides produced by treatment, out of ore and ore treating receptacle, by passing rapid current of chlorine gas, under superatmospheric pressure, through ore and ore treating receptacle; collecting, condensing them; collecting, storing for reuse excess of chlorine gas used; treating powdered ore with rapid current of chlorine gas, under pressure, at temperature of 360° Fahrenheit, raising it slowly to 755° Fahrenheit, maintaining higher degree, continuing rapid current of chlorine gas, under pressure, for one to three hours, according to nature of ore; then treating powdered ore at temperature of 755° Fahrenheit, with current of hot hydrogen gas and superheated steam for one-half hour, remove base metal compounds, or chloride of silver, deposited as film on precious metals before, or during previous treatment; to remove excess of chlorine gas used in previous treatment; prepare powdered ore for further treatment; treating powdered ore with hot vapor of mercury, under superatmospheric pressure, one-half hour to amalgamate floured gold; prepare coarse gold for treatment; then treating powdered ore with water holding free chlorine in solution; whereby base metal chlorides and precious metal chlorides, except chloride of silver, not removed by previous treatment, are dissolved and removed from pulp by filtration; treating filtrate with solution of sulphide of sodium; whereby chloride of metals in solution are precipitated as sulphides; treating pulp with solution of hyposulphite of soda; whereby chloride of silver is dissolved; removing chloride of silver from pulp by filtration; precipitating from filtrate chloride of silver with solution of sulphide of sodium, sulphide of silver.

APPARATUS FOR HANDLING ORES, ETC.—No. 733,647; F. K. Hoover and A. J. Mason, Kansas City, Mo.



In plant for handling ore and other material, combination unloading devices located along dock or other place delivery, stationary temporary receptacle within reach unloading devices adapted receive cargo of vessel or other carrier, and transfer truss or frame equipped with carrying devices located inland receptacle and capable reaching every part of latter and serving transfer its contents inland receptacles.

PROCESS OF MAKING LITHARGE.—No. 733,896; J. W. Bailey, Jersey City, N. J.

Process of making litharge which consists subjecting metallic lead to flame of hydrocarbon fuel atomized by jet steam.

PROCESS OF SMELTING METALS AND METAL COMPOUNDS.—No. 733,578; G. Egly, Charlottenburg, Germany.

Process of smelting metals consisting in smelting same in electric furnace, lower carbon electrode which is covered by scoria possessing sufficient conductivity and remaining solid or nearly solid at temperature at which smelting process takes place.

Mining Summary.

Specially compiled and reported for the MINING AND SCIENTIFIC PRESS.

ALASKA.

G. Mitchell reports having taken up his options on the Simenstad and Conley-Little groups of claims on Galena Bay, and signed a two-years' lease and bond on the Blel property. The option on the Gladhaugh mine is not yet closed, pending further negotiations. He expects to begin development work this season on these groups and also on the Bell & Gilneau groups in Copper River district, near Valdez.

The Nowell hydraulic plant in Silverbow basin, near Juneau, has started up. Another pipe line will be built and an additional giant put in.

The Spokane-Alaska Oil Co. has been incorporated at Spokane, Wash., to drill for oil in Washington and Alaska, by J. A. Finch, M. J. Sinclair and C. Hussey.

The De Soto Placer M. Co., owning ground in Council City district, are putting in a dredger and other machinery, says President De Soto. The dredger will be used on the company's claims on the Neukluk, and has a capacity of 10,000 yards per day.

ARIZONA.

COCHISE COUNTY.

The Postmaster mine and Oriental mill, near Bisbee, will start up for a steady run next week, says the Review.

MARICOPA COUNTY.

(Special Correspondence)—The Wickenburg smelter will be blown in in a few days. The mines of the district furnish all the ore that can be used.

It is reported that one of the deposits of bismuth ore in this county is to be worked.

It is reported that the stamp mill recently erected at Buckeye by Burson & Langley is in operation.

J. K. Murphy, of the Black Rock mine, near Wickenburg, is preparing for a shipment of mining machinery which will arrive at Wickenburg in a few days.

Wickenburg, July 20.

C. F. Goddard of the Goddard M. Co., operating a group 2½ miles from Wickenburg, says preparations are being made to put machinery on the Daniel Webster claim and sinking will begin by Sept. 1.

The Quishenberry mine, on Castle creek, near Wickenburg, will be reopened by J. H. Aaggard with Phœnix men.

MOHAVE COUNTY.

Work will be started on the Maguire mine, near Kingman, recently taken over by E. R Holden & Co. of New York. Water for a plant has already been developed and machinery will be put in.——At the Treasure Hill mines a whim has been put in, the intention being to sink the shaft to depth of 200 feet. At the 200 level crosscuts will be run to the Dictionary and Time Check. L. M. Teal is superintendent. —— Sinking on the Gold Road mines, near Kingman, will be resumed. A 30 H. P. gasoline hoist will be put on the 100-foot level to carry the shaft below that point.

PINAL COUNTY.

(Special Correspondence).—Superintendent J. H. Pratt, of the company operating the Golden Fissure group of claims, near Florence, says more men are being put on and development work increased.

Florence, July 20.

SANTA CRUZ COUNTY.

L. A. Teague, C. W. Hibbard and C. O'B. Reddin of San Francisco, Cal., are reported to have bought an interest in the mining properties of G. Schwab, consisting of two groups, 4 miles north of Calabasas, and organized the Calletano M. & S. Co. Development work started this week. The ore values are in silver, copper and gold.

YAVAPAI COUNTY.

(Special Correspondence).—The fire in the United Verde mine, which was supposed to have been extinguished by means of carbonic acid gas some months ago, is still burning and making increasing headway. It is now on the 500-foot level and slowly progressing downward toward the 700 level—the bottom of the mine. If the fire were confined to the timbers, there would be no particular difficulty in controlling and eventually extinguishing the fire, but the sulphide ore is burning, and it discharges great volumes of sulphurous acid and carbon dioxide, and cannot be reached by any other way than flooding the mine with water, and water is not available for this purpose. It is now thought the fire can never be extinguished until it burns itself out for lack of combustible material (sulphur), which now keeps it going. Mining is in progress in other parts of the mine.

Jerome, July 19.

The 100-ton mill at the Iron King mine of the American C. Co., near Val Verde, 23 miles southeast of Prescott, was put in operation last week.

A half interest in the Rosaline group of claims on Copper creek, owned by W. Nellis and J. Mayer, has been sold to D. N. Bartholdi of Jerome, who will start development work this week.

The Josephine M. Co. has started up work on the Black Lode near Pickerell's camp, near Jerome. —— Work will be resumed on the Verde Chief mines in Black canyon, near Jerome.

It is expected the Home Run mine at Groom Creek will be in operation by August 15.

D. N. Bartholdi has bought a half interest in the Rosalie group of claims on Copper creek, south of Mayer.

Superintendent Tibbett of the Pfau G. M. Co., operating the B B property near Cherry creek, reports work progressing and fourteen men working three shifts. A gasoline hoist has been put in.

ARKANSAS.

NEWTON COUNTY.

The North Arkansas Land Co, of Jasper, has been incorporated with J. B. Moss, W. P. Spears and B. F. Ruble as officers.

CALIFORNIA.

ALAMEDA COUNTY.

Superintendent Newhall, of the Phœnix quicksilver mine, southeast of Livermore, and owned by A. Hayward, of San Francisco, reports at the end of the 1200-foot tunnel the vein was struck, showing a thickness of 47 feet. The ledge was again cut in driving an air shaft on a higher level. One oven for the reduction of ore is being built. More brick is in the kilns for the second one.

AMADOR COUNTY.

At the Defender mine, F. B. Joyce, superintendent, near the Mokelumne river, in Pioneer district, 7 miles from Pine Grove, the 10-stamp mill is running steadily on high-grade ore ——The Grand Prize mine (the Horn & Andrews mine), near Pioneer, is being developed. A hoist has been put in and a shaft is being sunk. It is down 100 feet.——The Tom & Dick mine, adjoining the Defender, which has been worked at intervals for a few years past, will be operated again, work beginning this month, says Superintendent Turk. The 5-stamp mill is run by water power.

CALAVERAS COUNTY.

The starting up of the new 120-stamp mill of the Royal Con. M. Co. at Hodson was made the occasion for a celebration on the 21st inst. This is the largest individual mill on the Pacific coast outside of the Treadwell mines in Alaska. A full description of this property will be found in the issue of the MINING AND SCIENTIFIC PRESS of May 23, 1903. J. C. Kemp Van Ee is manager, and the company is made up of English men.

FRESNO COUNTY.

Bryner & Smith have drilling operations under way in the Devil's Den district, 20 miles from Coalinga.

INYO COUNTY.

The Anabarbara Co. at Ballarat started their 10-stamp mill last week.—— The Radcliff mine continues working twenty men. They are running one shift in the mill.——The Cecil R. Co. have replaced their steam power with gasoline and are putting in a 30 H. P. gasoline engine for their mill.——Flint Bros., owners of the Tuba Canyon mine, are cyaniding. They expect to start up their mill September 1 with increased capacity, says the Randsburg Miner.——The Golden Argus Co., of Snow's canyon, have let a contract on their tunnel and expect to start up their mill by September 1st.——J. C. Cress is putting in a gasoline engine at his mill near Ballarat and expects to start up next week.

KERN COUNTY.

Pumping oil by means of natural gas from the well is the latest plan of operations to be adopted at the Kern river field near Bakersfield. Last month the East Puente Oil Co., owned by San Diego men, put in such a plant which has been giving satisfaction, and this week the Associated Oil Co. has put one in on its Red Bank lease in the same section. The gas is allowed to flow into a gasometer, and from this it is supplied to the engine.

The Standard Oil Co.'s Bakersfield-Point Richmond (Contra Costa county) pipe line is in operation, oil reaching the refinery tanks at Richmond on the 19th inst. Now that the line is in working order, the company proposes to enlarge its refining plant at Point Richmond. Additions to the stills and retorts will be made. There are 700 men at present at the plant. Two tank barges are loading oil at the company's wharf for foreign shipment. The pipe line is 350 miles long, 280 miles on the main run and 70 miles in branches. On the main line the pumping stations are 10 miles apart.

Building will begin next week on the plant of the Pacific Smelting Co., near Bakersfield. The surveys have been made and the smelter will be located on the McKittrick branch of the Southern Pacific. There will be two 50-ton furnaces.

G. Sanderson has a lease on the La Grange claim, in Stringer district, near Randsburg.——C. Taylor, S. Tyler and F. Rose have a lease on the Mattie mine and are stoping on the 165-foot level and running a drift on the 120-foot level.

The Associated Oil Co. is starting to drill new wells in both the McKittrick and Kern River fields. The 408,000-barrel reservoir at Kern river, near Bakersfield, is completed, and work is being pushed on the McKittrick reservoir.

NEVADA COUNTY.

It is reported arrangements are being made to reopen the Thomas (New England) quartz mine on Gold Flat, near Nevada City, owned by R. C. Walrath of Nevada City and the estate of A. Walrath.

The mill at the Grey Eagle mine, near Maybert, is again in operation, after a temporary suspension due to the water supply being shut off by a break in the flume. Superintendent Kaler reports a new body of ore was opened last week in an upraise started 150 feet in the tunnel. The ledge is 14 feet wide.

The F. Brophy placer interests on Shady creek, near North San Juan, have been taken over by R. I. Thomas of Nevada City and J. A. Yeatman and C. L. Miller of San Francisco. A centrifugal gravel pump, with a capacity of handling 100 cubic yards of gravel per hour, and other hydraulic equipments, will be put in.

At the Buckeye mine, in Willow Valley district, near Nevada City, the drain tunnel is in 170 feet, with 150 feet more to the main ledge. A 10-stamp mill will be built.——A compressor is being set up at the Sterling mine. —— The Lecompton mine is putting in an additional pumping rig and a heavier hoist, says Superintendent Nihell.——H. L. Body reports work progressing on the 10-stamp mill that is to be put up at the Posey.

R. I. Thomas, S. M. Cheyney, W. A. Palmer, et al. have bought 140 acres of land in Penn valley along Squirrel creek, near Grass Valley, which will be used for dredge mining.

ORANGE COUNTY.

The Olinda Crude Oil Co., operating near Fullerton, has changed its name to Olinda Land Co.

PLACER COUNTY.

The Sacramento Dredging & M. Co. is building a dredger to operate on the North Fork above Colfax.

T. H. Wilkins, president of the California M. Co. which recently bought the Cedar Creek drift mine at Shady Run, says he has twenty men at work at this mine, which has been drifted 1400 feet into the gravel. Steam is used for power, but they expect to put in electricity next month.

PLUMAS COUNTY.

At the Plumas G. M. Co., Ltd., mine on the north side of North canyon, adjoining the Johnny Bull group, near Greenville, W. D. Lawton has a bond on it and preparations are being made to build a 15-stamp quartz mill. It is to be completed by Sept. 1st. The company will also put up a cyanide plant to handle the concentrates. Water power will be obtained from the Round Valley Reservoir. Five Impact wheels will be used, one to supply power to each, the rock breaker, the batteries, air compressor, concentrators, and an electric generator. The last named will be of 75 H. P., to light the mill, mine, etc., and to run a train of ten cars for the delivery of ore to the mill.

At the Johnny Bull group of mines in North canyon, near Greenville, under bond to Droege Bros. of Covington, Ky., and F. W. Day, who have organized the North Canyon M. & R. Works, the cyanide plant continues in operation, handling rock from the 5-stamp mill.

SAN MATEO COUNTY.

The Paxton Oil Co. has resumed drilling in its well at 1560 feet in oil bearing stratum. While waiting for a string of 5⅝ casing 200 feet of 50 gravity oil has raised in the well, says the Reporter.

SHASTA COUNTY.

Superintendent W. Hooper of the Inca Treasure G. M. Co., operating the Inca Treasure mine west of Delta, reports shipping ore to the Keswick smelter averaging $20 in gold per ton.

E. F. Adams, as president of the Northern California G. M. Co, has filed notices of location of seven claims, being the Summit in Bully Hill district near Winthrop, and the Douglas, Little Surprise, Friday No. 1, Saturday No. 1, Washington No. 1 and Little Tenderfoot in North Cow Creek district.

The Americus M. Co. has bought the Americus, McGinnis, Homestake and Ormolu claims, southwest of Redding.

The Old Spanish mine, in Lower Springs district near Redding, will be reopened, work resuming this week, after an idleness of three years, says B. M. Newcombe of Oak Hill, Napa county, a stockholder in the Old Spanish G. M. Co. that owns the mine. S. Davis is superintendent. There is a mill and a pumping plant on the ground.

SIERRA COUNTY.

At the Telegraph Drift M. Co. mine at Fir Cap near Downieville, Superintendent J. W. Finney reports work on the stamp mill progressing. He is also putting up a sawmill near the mine to get out lumber for the stamp mill and other buildings.

C. Brown, of Alleghany, has bought the Wright half-interest in the Gold Nugget placer mine, near Alleghany, for $1500—W. Barrett retaining the other half-interest.

The Gold Canyon quartz mine, on the north bank of the Middle Yuba river and 6 miles above Moore's Flat (Nevada county), has been bought by Manager F. B. Hill, of the Oriental mine, for a New York company, who have started development this week. A tunnel will be started from the river at a point 1000 feet below the apex of the ledge, and later a plant will be built on the mountain and a shaft sunk.

At the Tabor mine, on the Gibsonville ridge, near Gibsonville, they are widening the track from a 16-inch to 18-inch gauge in the main tunnel, and an electric plant is being installed. A. F. Eaton of San Jose is superintendent.

TEHAMA COUNTY.

Near Bee Gum, J. Hesselwood of Red Bluff reports making preparations to develop a body of iron ore. He has filed twenty-two mining locations and has a ledge 200 feet across. It is 37 miles northwest of Red Bluff, and is near the proposed route for the railroad to connect Red Bluff and Eureka.

TRINITY COUNTY.

Work is reported progressing in the Potillo quartz mine, owned by F. and P. Potillo, and at the General Lee and Klondike quartz mines, owned by J. Isbell and Meckel brothers. These mines show free gold. The General Lee and Klondike are extensions of the Potillo, all at the head of West Weaver creek, near Weaverville.

H. E. Pickett of Placerville, who has a bond on the Egan Flat placer mine at Junction City, will prospect the same with a drilling machine, and a dredger will be built if the prospects are satisfactory, says the Trinity Journal.

The Brown Bear mine at Deadwood was sold this week by the sheriff, under execution, for $31,000 to M. A. Phillips of Oakland.

TUOLUMNE COUNTY.

Sinking from the 500-foot level continues at the Mt. Jefferson mine at Groveland and it is the intention of Superintendent Meighan to go to a depth of 800 feet. On the 500 they are drifting on a 6-foot vein.

Work at the Crystalline mine, near Jamestown, is suspended.

E. C. Day of Columbia, superintendent of the Black Slate and Tapple mines, one mile north of the Rawhide mine, near Jamestown, has men at work clearing ground for several buildings, including a hoist.

The Campo Seco mine, near Jamestown, is closed down pending installation of a heavier air compressor, says J. H. Hall, superintendent.

The trouble at Stent and Quartz between the managers and the men has been adjusted. The lockout has been raised at the Jumper, Golden Rule and Mazeppa mines at Stent and at the Santa Ysabel mine near Quartz. The settlement is a compromise. Manager Kerr of the Jumper Co., acting for several companies, conferred with the officers of the union and an agreement was reached, by the terms of which all the underground men except muckers are to receive $3 for ten hours' work and surface men of all kinds are to return to work at the same wages paid before the trouble began. The agreement lasts for six months. The App mine, which is one of W. A. Nevill's properties, is not a party to the agreement.

YUBA COUNTY.

Near Oroville, a company composed of B. C. Warnick, P. Russ, S. Presser, A. Buchanan and A. L. Solenburg of Pennsylvania and H. W. Knight of Overbrook, Or., has bought the Marigold dredgers and land.

COLORADO.

CUSTER COUNTY.

The Ute Creek G. Co., composed of Boston, Mass., men, has bought the Burnette claim at Querida.

DENVER COUNTY.

(Special Correspondence). — The strike situation at the Denver smelters remains unchanged. No trouble is feared at the Durango plant, as the men have not fully recovered from the effects of the strike of a few years ago, and they are not willing to enter into another strike unless compelled to.

Denver, July 21.

DOLORES COUNTY.

(Special Correspondence).—The United Rico Mines Co. are sinking a shaft through the Devonian limestone, which is impregnated under the fault fractures with lead-zinc ore carrying an average of eleven to twelve ounces in silver. The company owns 1100 acres at Rico. They will remodel the old mill and also build a new one.

Rico, July 20.

FREMONT COUNTY.

The Florence Con. Oil Co. has started drilling another well for oil. The Consolidated has one well pumping. Two other wells are being drilled by companies on adjoining ground. The Columbia Crude Oil Co. has started the drill in well No. 2. A. P. Mackey and H. Graham of Denver are interested. The Keystone Oil Co. is boring in well No. 6 and is down 1800 feet with favorable indications. It is estimated there are thirteen wells being put down in the Florence belt at this time and six more wells are projected, work on which will begin before the end of the summer.

The United Oil Co. has bought a block of 1200 acres of ground 2 miles south of Florence and will start drilling there. There are some producing wells on the ground.

GILPIN COUNTY.

E. C. Sherman and T. R. Cudahy of Central City have incorporated the Mont D'Oro M. & M. Co. to operate the New Century group (the Tippecanoe group) of claims on the north slope of Winnebago hill, in Quartz Valley district. They are sinking a shaft, have reached a depth of 70 feet, and report a 4-foot vein of milling ore, with a smelting streak showing an average width of 4 inches. Hoisting is being done with a windlass at present, but they will put in machinery.

GRAND COUNTY.

(Special Correspondence). — Forty-five miles of the Moffat line, which will extend through Grand and Routt counties, is nearly graded. A machine is being used for laying the track. A large tunnel will be driven through the divide.

Denver, July 21.

HINSDALE COUNTY.

The Bullion King mine, owned by B. F. Cummings of Lake City, and in the Burrows Park district, is to be developed. The Bullion King is said to be on the Illinois Boy vein, which carries copper and gold ore. Cummings proposes to open the ore measures by a crosscut tunnel.

LAKE COUNTY.

(Special Correspondence). — Leadville business men have formed an alliance for the purpose of combating the labor organizations.

Leadville, July 21.

LA PLATA COUNTY.

(Special Correspondence).—E. W. McConnell of Durango has men at work on the Southern Boy mine, near La Plata City. The tunnel is in 645 feet and drifting for the Southern Boy vein. They have cut one vein which runs well. E. N. Beach is manager.

The county commissioners have agreed to spend $5000 on a wagon road from La Plata to the county line between La Plata and East Mancos, if J. Doyle will build the road from East Mancos to the top of the hill. There is already a good trail between the two places. Doyle says he will start work shortly from his end of the line. A good wagon road over this range will greatly shorten the distance to the railroad. Manager Doyle of the East Mancos G. M. Co. intends building a mill on the La Plata side and to put in a tramway from the mine to the mill. Several other properties are working a few men in the neighborhood of La Plata.

La Plata, July 18.

SAN JUAN COUNTY.

(Special Correspondence).—The Silver Wing mill, owned by the Eureka Exploration Co., has closed down. They have been making test runs on ore from the Silver Wing and Frederica mines and will put in a tramway, 1 mile in length, from the Frederica to the mill. This same company owns the Ridgway and Scotia mines, being operated by lessees who are taking out some rich ore from the Scotia. J. H. Moreland is manager.

The Silverton, Northern Railway has started work on the line from Eureka to Lake City, a distance of 35 miles. They expect to have the road completed to Animas Forks this year. The grade will average 5%.

Eureka, July 18.

(Special Correspondence). — It is reported some of the mines in this locality are unable to run full capacity owing to scarcity of miners.

The Smuggler-Union M. Co. are handling 400 tons of ore per day. Everything is running smoothly, says Manager Buckeley Wells.

Telluride, July 20.

TELLER COUNTY.

The Gold Bond M. Co. has given a lease to Sider & Co. on the north end of its Gold hill ground at Cripple Creek, which adjoins the Moffatt tunnel. The lease is for two years with royalties ranging from 20% to 25%, and it is expected it will be worked through the tunnel.

At the annual meeting of the Golden Cycle M. Co, held at Colorado Springs last week, the head offices were changed from Denver to St Louis, Mo. Their mines are at Cripple Creek.

Stoveken & Zimmerman have leased the Beatty mill at Goldfield and will convert it into a cyanide mill for the treatment of the low-grade ore of the dump of the Theresa mine.

The August Flower Leasing Co., operating on the Chickenhawk claim on Guyot hill, Cripple Creek, have put in a heavier plant of machinery, capable of hoisting from 1000 feet.

The Great Western Co. has put in a plant of machinery on its Orange claim on Trachyte mountain, near Cripple Creek. The shaft has been sunk to a depth of 80 feet.

Operations were resumed last week by the Lincoln Mines Co., at the Lincoln mine, on Globe hill, Cripple Creek, their surface plant having been rebuilt after loss by fire. Manager F. A. Wright says the new plant is of heavier capacity, capable of hoisting 1000 feet, also a five-drill compressor. The shaft is down 200 feet, and sinking will be resumed to the 400-foot level. It is intended to build a cyanide mill also.

IDAHO.

BINGHAM COUNTY.

The Pittsburg mine, in Mount Pisgah mining district (Caribou district), consisting of a group of twelve claims, together with mill and other improvements, water rights, etc., were sold by the receiver last week, being bid in by McCornick & Co. of Salt Lake City, Utah, for $25,000. They propose to improve the mill and develop the group.

BLAINE COUNTY.

The Carbonate Hill M. Co. has been incorporated at Hailey by H. J. Davis, C. B. Dunton and D. E. Moulton, of Portland, Me. W. A. Brodhead is local agent in Hailey. The company owns the Black Carbonate lode, located at the head of Wood river, above Galena, and also the Maine lode on Cherry creek.

CUSTER COUNTY.

The Challis Messenger says it is reported negotiations are under way for a consolidation of the mines owned by the Ramshorn M. Co. at Bayhorse, and the mines owned by the Omaha S. Co. at Clayton. It is expected the railroad will be extended up Salmon river.

IDAHO COUNTY.

H. Brant, operating a group near Roosevelt, in Thunder Mountain district, says he is sacking ore for shipment. He proposes to put up a 20-stamp mill this season.

OWYHEE COUNTY.

Bruton & Ellis of Nampa and Salt Lake City, Utah, have a bond on the Sugar Loaf group of claims, near Silver City, and are making preparations to begin development work. The ore can be worked by cyaniding.

SHOSHONE COUNTY.

The Reindeer M. Co., operating 3½ miles southeast of Mullan, in the copper district, started its new compressor last week. It is operated with water power under head of 500 feet.

Twenty-two hundred men are employed in the mines and mills of the Cœur d'Alenes and the monthly payroll aggregates $200,000, says the Deseret News. The wages for underground men are $3.50 per day except at Wardner, where the wage is $3 per day. The number of men in the mills and mines of the district are distributed as follows: Morning, at Mullan, 317; Bunker Hill & Sullivan, at Wardner, 300; Tiger-Poorman, at Burke, 300; Standard, at Wallace, 291; Last Chance, at Wardner, 194; Mammoth, at Wallace, 177; Frisco, at Gem, 157; Hecla, at Burke, 116; Gold Hunter, 66; Hercules, 60. In addition to these, there are a number of smaller ones in the district that are working from three to fifteen men, which bring the total up to 2200 men.

KANSAS.

NEOSHO COUNTY.

J. H. Cook of Carthage, Mo., operating with Illinois men in the Chanute oil and gas district, reports organizing a company to lease 10,000 acres of land north and west of Golden City, to prospect for oil.

WILSON COUNTY.

The Prairie Oil & Gas Co. has bought a tract of 153 acres, 1½ mile north of Neodesha, and will establish a "tank farm." Two 55,000-barrel tanks will be removed from Texas and set up there, as well as building other reservoirs. It will be made the central storage station for Kansas and Indian Territory.

MICHIGAN.

BERRIEN COUNTY.

The Michigan Oil Co. has been organized at Niles to drill for oil. They have leased 1500 acres west of Niles and will start work this month. At Three Oaks the Southwestern Michigan Oil & Prosperity Co. has been organized and has leased 4000 acres near Galien.

HOUGHTON COUNTY.

The Lake Superior Smelting Co. at Dollar Bay is building two more furnaces, due to the increase of mineral to be smelted. One is to refine mineral reduced in the cupola and the other is a regular reverberatory smelting and refining furnace. The Michigan, near Houghton, has cut the Minnesota conglomerate by crosscut from the Calico lode in the 11th and 13th levels.

Ground has been broken on the east side of the Champion mill at Freda, west of Painesdale, for the head additions. Two heads are to be added, giving six in all. New devices to crush the "ragings" from the present heads are being tried by the Champion. A pair of heavy crushing rolls have been set up in the west end of the mill and a Chilean mill is going in, for separating the tailings from the rough jigs. If the experiment proves successful one pair of rolls will be required for each head and a Chilean mill for every two heads, says the News.

The average mineral yield of the Winona mine at Winona for June was forty pounds of copper per ton of rock stamped. The last of the company's stock pile has been treated and hereafter rock shipments will come direct from the mine openings.

At the Franklin mine, near Hancock, on the seventh level south in the Junior, the management have struck copper ground 266 feet south of where No. 2 shaft will be sunk. It has been crosscut for 12 feet. The drift will be continued ahead and a machine put behind the drift to open further. This Albany & Boston conglomerate is to be further developed.

The No. 7 shaft at the Quincy mine at Hancock is sunk to the 56 level and the openings below the 14 are said to be uniformly good. Rock shipments from this source aggregate 1000 tons daily. At the mill six stamps are treating the entire output instead of eight as formerly. The two idle heads are being changed over to the coarse system of stamping. The Quincy is stamping at the rate of 900,000 tons of rock per annum.

KEWEENAW COUNTY.

The foundation work for the new stamp in the Mohawk mill, near Allouez, is progressing, as also the surface improvements at the mine, and they expect to supply rock to three stamps by Aug. 1st.

At the Phœnix mines at Phœnix the dam across the Eagle river, 3000 feet above the mill, is finished. The water will be carried through the flume, 12x24 inches, to the mill and this will be sufficient for all purposes until the mill is enlarged, when the dam can be thrown across, 2000 feet below, giving all the power that will be required, says the News. The mill will go into operation by August 15th.

MISSOURI.

JASPER COUNTY.

C. A. Emery, S. A. Stuckey, S. Chitwood, C. J. Smith, B. L. Van Hoose and J. Flory, who own the VanGuard mine, on the Amsden land, northwest of Carthage, report making a lead strike in their mine at depth of 20 feet, a prospect drill having previously located the ore.

Heavier pumps have been added to the plant of the Missouri Zinc Fields Co., near Joplin, and their mines unwatered, so that the mines on this lease can be worked below the 200-foot level.——The Winner Lead & Zinc Co., who bought the Reagan lease, south of the Georgia City mines, adjoining the O., M. & R. on the east, near Joplin, expect to be running dirt through their mill that will produce fifteen tons per day.——G. E. Forrestall, owner of the Florence F. mine on the Forrestall & O'Donald lease, will sink the mill shaft from 165 to 240 feet and drift, says the News.

At Webb City, the Bosch Scogin M. Co., having unwatered their mine, have resumed operations. They have put in a heavier pumping plant.

The Leo M. Co., at Webb City, have their mill in operation.——Construction work has started on the third mill of the Aylor twelve acres, leased by Patton & Dodge. The plant will be known as Avondale No. 2, the other two being Avondale No. 1 and the Dominion. The new mill will be 250 feet from No. 1. The conditions of the lease were that a mill should be built on each four acres. The new shaft on the Holy Smoke, on adjoining lots, is down 80 feet and in ore.——The Webber M. Co. has put in two 8-inch cross-head pumps in the Hayseed mine.

J. Mortoo, for the Con. Troup M. Co., has bought the J. Dermott tract near Webb City, covering forty-five acres, for $50,000. This land adjoins the Pleasant Valley mines on the south and is partially developed. The Troup Co. are owners of the Hudson mine, which is near this lease.

The Narragansett mine and mill, north of Webb City, on the spur of the Memphis Railroad, has been sold to a company of which C. E. Force of New York is manager. The mill will be put in operation.

The Waddell Zinc Co.'s mill is ready to start. It is 3½ miles northwest of Carthage, in Waddell mining district.

The Cornucopia M. Co., composed of C. Ball, A. M. Wagoner, O. Duenweg et el., is building a mill at Alba which is about finished.

MONTANA.

FERGUS COUNTY.

N. J. Littlejohn of Lewistown has a bond on a group of prospects in South Moccasin mountains, near Kendall.

M. J. Hall of Maiden says he will build a cyanide plant to work the ores of the Maiden Queen claim, north of Maiden, and adjoining the Maginnis mine on the north. —— P. Rousseau has a cyanide plant in operation on his group near the Spotted Horse mine, near Maiden, and is making it pay the expense of developing his mine.

FLATHEAD COUNTY.

G. Robinson of Libby reports having bought the Cain group of claims in West Fisher district, and a company will be formed to operate them. There are four claims in the group and they are on Great Northern mountain, below the American Kootenai M. Co.'s ground. —— It is reported J. H. Greiger, manager of the Illinois & Montana M. Co., has made arrangements to resume work on that company's group in West Fisher district, near Libby, says the Inter-Mountain, and they will also build a mill.

Work is reported progressing at the Banner & Bangle mine, 6 miles south of Troy, operated by Larson & Greenough under a bond. As soon as the road from Troy is finished shipments of ore will be started. Also they propose to build a concentrator at the mine.

GRANITE COUNTY.

At Henderson gulch, near Phillipsburg, Superintendent C. E. Van Barneveld has men at work prospecting on 500 acres of ground which the company has under option. Tests are being made preparatory to working by dredging.

J. H. Grant, part owner, operating the Dakota mine, adjoining the Bluebird, near Willow creek, near Phillipsburg, reports opening up a 3-foot body of gold ore, carrying also 1% copper. He has a Huntington mill in operation. Cyanide tests are being made on a large body of low-grade ore.

A system of exhaust fans and flues have been put into the dry-crushing mill of the Granite-Bimetallic Con. M. Co., near Phillipsburg, to carry off the dust from the batteries.

D. H. McDonald and L. N. Van Vranken have a lease on the Salmon mine at Tower, near Phillipsburg, and begun development work with W. G. Harper in charge. —— O. Smith is operating his cyanide mill on Lower Rock creek, near Phillipsburg. Arrangements are being made to enlarge the plant. —— It is reported the Bimetallic mill will be dropping 100 stamps by August 1 instead of 50.

JEFFERSON COUNTY.

Manager G. B. Drankenfeld of the Montana Mineral Land Dev. Co. says development work has been resumed. The company owns the Eva May mine in Cataract district, near Basin, but has not worked it for three years. Arrangements are being made to build a smelter for the treatment of their sulphide ores.

The Pittsburg Smelting Co. has bought the Jacquemin iron properties near Corbin for $60,000. The ore will be used for flux in the smelter built by the company south of Butte. —— The Evening Star

mine, 6 miles from Basin, leased by the Pittsburg Co., will have a new shaft to he sunk 350 feet, as the old shaft is in bad condition.

In Cataract district, near Basin, men have been put to work by the Cataract C. M. Co. on the smelter, which is being built, and to develop the ore bodies in the Crystal mine, one of the group owned by this company.

LEWIS AND CLARKE COUNTY.

J. C. Cory et al., who control the King Solomon mine near Helena, report development work progressing, opening up in a winze in new workings an ore body which carries high-grade silver ore.

Operations are again under way on the North Star mine, near Marysville. Preparations are being made to start up the Bald Butte mill, which has been shut down for a short time ——There is greater activity in the Wickes-Corbin district, 21 miles from Helena, than for a number of years.

MADISON COUNTY.

Near Pony timbering shaft No. 2 of the Norwegian M. & Dev. Co. is finished and development work begun.——Work continues on the Strawberry mine. A crosscut is being run to the hanging wall from the face of the drift. The mill will he started up.

NEVADA.

ELKO COUNTY.

Manager G. L. Moats of the Latham M. Co., operating in the Spruce Mountain district, near Clover, south of Wells, says the mill has been started and is giving satisfaction. Owing to the scarcity of water, the full capacity of the plant is not being used, only twenty-five tons of ore being put through the crushers daily. The concentrates produced average 56% lead, 10 ounces silver and $3.20 gold.

LINCOLN COUNTY.

Operations are reported suspended at the El Dorado canyon mines at El Dorado canyon for the summer, and will not resume until September 15 on account of the extreme heat.

The Gordon M. & M. Co. has been incorporated at Salt Lake City, Utah, to operate a group of five lode claims in Old Highland mining district; R. G. Bosley, G. W. Poague and S. Fowler.

LYON COUNTY.

The company has men at work cleaning out the Douglass ditch at Dayton. The Federal M. Co. of Como will begin operations with its mill as soon as the water is turned in to produce the power.

NYE COUNTY.

The Sapho group of claims at Tonopah has been bonded by E. W. Griffith & Co. for $100,000.

The Arivada M. Co. has been incorporated to operate a group of seven claims near Tonopah; J. S. Cook, W. Rogers, I. Morasci and W. McWilson.

T. J. Lamoraux, president of the Tonopah-Aspen Co., has started work on their three claims, the Aspen, Black Diamond and Sans Sahe, 1 mile north of the Tonopah and adjoining the Belle of Tonopah on the northeast.

The crosscut from the 770-foot station in the Ohio-Tonopah shaft at Tonopah is in 90 feet and has passed through the ledge cut at a depth of 730 feet in the shaft. The air compressor is being set up.

STOREY COUNTY.

The flume being built to convey ore pulp to the Butters cyanide plant in Six Mile canyon, near Virginia City, from the Best & Belcher mill is expected to he ready for use by August 1, and crushing rock from the Hale & Norcross mine waste dump will begin by August 10.

An electric drill plant has been put in at the Overman mine, near Virginia City.

WASHOE COUNTY.

In Olinghouse canyon, near Wadsworth, the Springfield-Nevada M. Co. have their mill No. 2 in operation after making alterations and increasing the capacity. Three feet of quartz has been cut in their Renegade mine, showing values of $8 in free gold. The raise in Cahin No. 2 has connected with upper level and another raise started, blocking out 100 feet of stoping ground.

WHITE PINE COUNTY.

For $5000 the Owl and Snowbird claims, in Granite mining district, near Cherry Creek, have been bonded to R. G. Smith of Salt Lake City, Utah.

NEW MEXICO.

GRANT COUNTY.

The Samson group of mines, 16 miles south of Silver City, and in the Burro Mountain district, has been sold to Canton, O., and Pittsburg men, W. Capthorn of Canton, O., manager, for $25,000. The group comprises five copper claims, and as soon as the best method of treating the ore is determined the company will build a mill.

SOCORRO COUNTY.

The Dividend M. & S. Co. is drilling for water at Estey City for the development of mines in Oscura district. The Colorado F. & I. Co. has twenty men working 15 miles north of Estey City, and if iron is opened in sufficient quantities to warrant it a railroad will be built from Ancho to Oscura to handle the product, says the New Mexican.

TAOS COUNTY.

Near Red River a wagon road has been finished up Placer creek to give access to several mines in that section. The Jayhawk and Scarlet have ore on the dumps ready to be hauled to the Jayhawk concentrating mill at Red River. Rogers & Luce Bros. have men at work on the Jayhawk and are taking out ore. They expect to cut the main vein. If this proves to he the case and the values hold out as hoped, they will probably put in a plant at the mine for the treatment of their own ores, leaving their mill down on the river for custom work. Their ores are gold and silver-bearing.

OREGON.

BAKER COUNTY.

Preparations are being made to put up a 10-stamp mill at the Belcher mine, near Sumpter, which will later he enlarged to twenty stamps, says President G. W. Daines. Water power will he used.

GRANT COUNTY.

J. W. Larkin and D. R. Evans, Spokane, Wash., owners of the Cougar mine, near Granite, have operations under way. The plant is being overhauled. Two new roasters of larger capacity will be built in place of those put in last season.

JOSEPHINE COUNTY.

Carr & Terry, of Galice, have bought the Bradford placer on Silver creek and will develop it, putting in hydraulic equipment. This ground is on a bench 150 feet above the creek bed. Todd creek, a tributary of Silver creek, furnishes a water right. The ground has been worked to some extent by hand.

Ingram & Ramsey are continuing development work on their copper group in Slate Creek district, near Grant's Pass. Assays show values of 10% copper.

LANE COUNTY.

(Special Correspondence) —At the Black Butte quicksilver mine the contract for a 450-foot crosscut tunnel on the 850-foot level was completed last week, and W. B. Dennis, manager and principal owner of the mine, has let a new contract for a 100-foot extension. In the first 450 feet three veins were cut—7, 12 and 20 feet wide, respectively—corresponding to the veins in the upper levels. There are over 12,000 feet of development work on the Black Butte mine, besides extensive surface improvements. The property consists of 1500 acres of land and thirty mining claims.

The Bald Butte quicksilver mine, in the Black Butte district, is owned by Portland, Or., men. The principal owner visited the property last week and is making plans for resumption of work at an early date. Considerable development work has been done, showing up a wide vein of low-grade ore.

Among the mines in the Bohemia district there is much activity in anticipation of the completion of the railroad, which is to give the camp an outlet by connection with the Southern Pacific at Cottage Grove. Work on the road is in progress.

Eugene, July 19.

WALLOWA COUNTY.

Eleven and one-half miles of wagon road will be built by the Tenderfoot G. M. Co. This company owns mining properties 18 miles southeast of Joseph. As soon as the road is completed to the Tenderfoot mines, a 20-stamp mill, with complete cyanide and concentrating apparatus, sawmill, etc., will be hauled in.

SOUTH DAKOTA.

LAWRENCE COUNTY.

T. T. Cornforth of Denver, Colo., chairman of the executive committee, and A. E. Phillips, superintendent of the Lexington Hill G. M. Co., at Deadwood, report machinery on the ground for the enlargement of the Highland Chief mill, in Spruce gulch, owned by the Lexington Hill Co. They will increase the leaching facilities to correspond with the full capacity of the crushing plant of twenty stamps.

The Lead Call says it is reported operations will be resumed at the smelter of the Golden Reward M. Co. at Deadwood, which was closed down last March on account of a strike. The Golden Reward Co., besides the 250 tons of ore mined to keep its cyanide plant in Deadwood in operation, mines 400 tons daily, which is sent East to outside smelters for reduction. It is said these shipments will be continued even after the smelter in Deadwood has again blown in. During the time the smelter has been idle many improvements have been made in the plant. The company's workings and plants require the employment of 500 men.

The Reliance G. M. Co. has been incorporated as a result of a consolidation of the University, Ak-Sar-Ben and other companies operating on the west side of Bald mountain, near Lead. A cyanide plant will be built on Annie creek.

Work is being resumed on the Brown & Pollack ground on False Bottom creek, 2 miles from Carbonate. Plattsmouth, Neb., parties are interested and are arranging to sink a shaft on the vein. This is a silver property.

The Homestake M. Co. will put in 100 additional stamps at the Amicus mill (formerly the Highland), in Lead, says Superintendent T. J. Grier, which will give the mill 240 stamps. It will give the Homestake Co. a total of 1000 stamps in its six mills. Grier denied the report that the company was contemplating the erection of an additional mill. To operate the increase of stamps the company will put in a compound engine in the west end of the mill and the old simple engine at the east end will be removed. The work of placing the new engine will be done first, and as soon as power can be supplied from that source the other will be dismantled, making it possible in this way for the company to operate the present 140 stamps while the others are being set up. It is expected to have the additional stamps running during the coming fall. They will be practically the same as the stamps in use in all the other Homestake mills, weighing 900 pounds apiece. The new air compressor at the Ellison hoist of the Homestake in Lead was put in operation last week. Its capacity is 150 drills at one time. This compressor will double the air pressure in the Homestake mine. An additional battery of boilers was put in to supply it with steam. Their cyanide plants are handling all the mill tailings at present.

PENNINGTON COUNTY.

All work has been stopped at the Holy Terror mine, near Keystone.

The Burlington M. Co., owning ground on the head of Friday gulch, near Hill City, is preparing to increase development work. The shaft will be continued down on the vein and later it is intended to put in more machinery for this work. J. B. Taylor is superintendent. They have a sawmill on the ground, which has been busy several months.

The Sunbeam M. Co., ½ mile from the Burlington, is building a 20-stamp mill. A shaft has been put down 300 feet and they are drifting on the vein from the bottom of the shaft.

The J. R. mine, near Hill City, owned by the Cumberland M. Co., is having an air compressor put in, says Manager Crocker at Deadwood. Cumberland, Ky., men compose the company. The shaft is 500 feet deep.

UTAH.

JUAB COUNTY.

To the battery of boilers at the Centennial Eureka, near Eureka, will he added a fourth of 150 H. P., giving a total of 600 H. P. This addition in compressed air required has been necessitated by the increase for the twenty drills and the hoists used underground. At the same time an additional stoker will be put in.

PIUTE COUNTY.

The holdings of the Mt. Baldy M. Co. on the gold-bearing zone extending south from the Annie Laurie mine on Gold mountain, near Marysvale, have been bought by the Log Cabin M. Co., of which P. A. H. Franklin of Salt Lake City is manager. P. S. Merrill of Buffalo, N. Y., president of the Log Cabin Co., says to open this ground a tunnel has been started from the Marysvale side that will be extended into the zone for 2000 feet. From the side on which is located the Elephant group a tunnel will be driven 700 feet.

The Wedge and Treasure Vault mines, in Mount Baldy district, near Marysvale, have been bonded to the Gold Vein M. Co. G. F. Dalton is manager.

At the Sevier Con. mines, near Kimberly, it is expected the mill will he ready for operations by Sept. 1, says Superintendent C. W. Foster.

SALT LAKE COUNTY.

The Queen M. Co. has been incorporated at Salt Lake City by D. T. Powell, E. Feller, J. K. Shaw and J. R. Morris.

The annual report of the Utah Con. C. Co., at Bingham, shows the average yield per ton of the 167,713 tons of ore treated (of which only 691 tons were oxidized ore) was 70.9 pounds of copper with $2.80 in gold and silver. These figures compare with 53¾ pounds of copper and $2.25 in gold and silver during 1901. The smelter treated an average of 460 tons of ore daily. Including expenses of every character, interest, maintenance and development, etc., and deducting the precious metals values from the total costs the company's product of 11,840,431 pounds of copper was made for 5.7 cents per pound against an average price of 11 9 cents received. The improvement in the character of the ore in 1902 over 1901 is shown by comparison of ore tonnage and its contents for the two years as follows:

	1902.	1901.
Ore treated, tons....	167,713	167,823
Copper, pounds.....	11,840,431	9,043,937
Silver, ounces.....	160,915	176,331
Gold, ounces.....	19,078	13,983

SUMMIT COUNTY.

It is expected the Keith-Kearns mill at Park City will be ready for operations by October 1, says the Deseret News. There are thirty-five men employed on construction of the plant.

UTAH COUNTY.

Development will be increased at the Union Chief mine, near Santaquin, for which additional equipment is being put in.

The Whirlwind M. & M. Co. has been incorporated to operate in American Fork canyon, near American Fork, with J. J. Mercer, C. W. Earl, E. J. Wild, J. H. Wootton, W. H. Greenwood, J. Greenwood and H. D. Wild as directors.

W. S. Lyle of California and W. H. Grant have a bond and lease on the Ontario group, near American Forks, and have started a new tunnel.

WASHINGTON.

FERRY COUNTY.

Manager Norman of the Apollo G. M. Co. says operations will be resumed at the California mine, near Republic.

Work will be resumed on the Nova mine, southwest of the Mountain Lion mine, near Republic.

The shaft going down from the tunnel level of the Morning Glory mine, near Republic, is completed to the No. 4 level, 300 feet below.

The News-Miner says negotiations are pending for resumption of work on the Nova mine, southwest of the Mountain Lion mine, near Republic. Two tunnels have been driven, cutting the vein at depths of 50 and 100 feet; a third started that would reach the ledge at 275 feet with depth of 150 feet and in 240 feet.

Manager A. Dunphy has men at work on the Mineral Hill group, near Danville. The company has twenty-six claims in the group.

J. L. Safford and A. Rambo, of Wardner, Idaho, have started sluicing operations on their group of placers near Republic.

WYOMING.

CARBON COUNTY.

A strike of copper ore is reported in the tunnel level of the Ferris-Haggarty mine, near Rudefeha, of the North American C. Co. at Encampment. The 16-mile tramway is reported transporting 300 tons of ore per day at a cost of $42, or less than 1 cent per ton per mile. J. S. Cary of Denver, Colo., is president of the company.

FOREIGN.

AFRICA.

TRANSVAAL.

Manager Way of the New Kleinfontein mine, near Johannesburg, reports during the month of May the eastern incline shaft of the New Kleinfontein Co. was sunk 213 feet 6 inches. The shaft is 21 feet by 6 feet and is down 2100 feet, where sinking will cease for the present. This shaft in five months has been sunk 858 feet and the whole of the unskilled work has been done by natives.

NATAL.

The Natal Navigation Collieries & Estate June output of coal was 11,128 tons.

AUSTRALIA.

NEW SOUTH WALES.

The S. & R. Co. of Australia report during month of June: Dore bullion was shipped to London containing 8743 ounces of gold and 52,550 ounces of silver; also, 114 tons copper matte, containing 239 ounces gold, 8550 ounces silver and fifty-five tons copper. The soft lead produced during the month and disposed of in the colonies was 515 tons.

QUEENSLAND.

The Brilliant Central G. Co., at Charters Towers, July 1, report: Crushed during month of June 3040 tons of quartz for a yield of 2219 ounces of gold; value of cyanide bullion, £1497.

TASMANIA.

The Mount Lyell M. & R., at Mount Lyell, July 2, report: From May 28 to June 24, inclusive, a total of 21,342 tons of ore were treated, the average assay value being: Copper, 2.02%; silver, 2.18 ounces; gold, .088 ounce per ton. The converters

produced during same period 496 tons of blister copper, containing: Copper, 491 tons; silver, 49,293 ounces; gold, 2070 ounces. During same period there were treated 5086 tons of metal-bearing fluxes and North Mount Lyell Co.'s ore.

BRITISH COLUMBIA.

Development work was started last week on the Clyde group, on Silver Cup mountain, owned by N. Emo of Ferguson, who also owns the Red Deer group in same section. The ore on these groups is a carbonate carrying values in gold.

The shaft at the Marble Bay mine, Texada island, which is down 400 feet, will be deepened and a heavier hoisting plant is being put up. The hoist is of 75 H. P., with 5-foot drum and capacity of 700 feet of cable.

The Boundary Coal Mines, Ltd., of Spokane, Wash., have bonded the property of the company to J. R. Carling of Exeter, Ont. A diamond drill outfit will be put in to prospect the ground. The holdings comprise 2560 acres in North Fork coal basin, 50 miles north of Grand Forks.

A third stamp mill on Wild Horse creek will be running before the end of the year, as the Pilot Ymir M. & M. Co. has made arrangements to build a mill. The mine is 9 miles up the creek from Ymir.

On the Oyster-Criterion mine, near Ferguson, men are at work on mill, aerial tram and power flume, says Manager W. B. Peal, and by Sept. 1 the mine will have the compressor, mill and aerial tram lighted throughout with electricity.

Development work has been resumed on the Betts & Hesperus group, owned by the Hesperus G. & C. M. Co. of Chicago, Ill. The group is on Hardy mountain, 4 miles from Grand Forks. C. Magee of Chicago is president.

C. Wolfe and J. F. Davanit of Spokane, Wash., have a bond on the Gold Cup group, 2½ miles north of Ymir and within 2 miles of the Nelson & Fort Sheppard Railroad. The ore is free-milling. A steam hoist and drill plant are being put in.

It is reported the strike in Dunsmuir's Cumberland mines has been declared off, the Mongollan strike breakers having been too many for the men. Little hope is entertained of the success of the proceedings against the company for employing Chinese underground, which Crown Counsel D. M. Rogers has started, who says a test case will be fought through the Privy Council in England, which some years ago killed a law similar to the present one.

CANADA.

ALBERTA.

The International Coal & Coke Co., operating coal properties at Blairmore, report work on the erection of 100 coke ovens is under way. It is expected they will be ready for use by Sept. 1.

ONTARIO.

Superintendent T. Campbell of the Seneca G. M. Co.'s mines at Tache, near Wabigoon, reports preparations under way for increasing development. Additional machinery, including a mill, will be put in. The company proposes to quarry the property for some time before sinking a shaft.——It is thought Michigan men, who are interested in the Beehive mine, near the Royal Sovereign mines, will reopen it. C. Brent of Rat Portage is manager.——W. P. Davidson of St. Paul, Minn., manager of the Royal Sovereign mines, says work will be resumed.

INDIA.

The Champion Reef G. Co. return for month of June: 14,895 tons of ore produced 14,960 ounces gold; 19,332 tons of tailings (cyanide process) produced 2332 ounces gold.——The Ooregum G. Co., at Ooregum, return for month of June: 11,911 tons of ore produced 5939 ounces gold; 10,135 tons of tailings (cyanide process) produced 1198 ounces gold.

MEXICO.

CHIHUAHUA.

The Terrenates M. Co. of Parral has decided to build a railroad from Minas Nuevas to its property.

La Luz G. M. Co., W. D. Pearce general manager, operating at Maguarichic, will put in additional machinery this summer.

It is reported that an option has been given on the Lluvia de Oro mine, near Urique, for $2,000,000 gold, to the United Mexican M. & E. Co., of which H. E. Cary of New York is a member.

M. Wicks, C. E. Delno of Austin, Tex., and W. J. Jones of Chihuahua have denounced 270 pertenencias of mineral ground in Santa Eulalia district, west of the Baltimore mine and on the mountain west from the railroad station of Santa Eulalia.

GUANAJUATO.

At El Cubo, near Guanajuato, a 30-stamp mill is being erected by El Cubo M. & M. Co. (the reorganized International M. & M. Co.). On Guanajuato river, Manager E. G. Spillsbury, for G. W. Bryant of Guanajuato, says plans are being drawn for building a dredge and concentrator for treatment of amalgam, etc., which have gathered in the river from the patios of Guanajuato.

MEXICO.

Two companies were organized at Mexico last week to operate in El Oro district: The Amistad Co., owning fifty pertenencias on the Descubridora vein and on which there is a shaft 100 meters deep. They intend to clean out the shaft and sink deeper, for which they are putting in hoist and pumping machinery. The officers of the company are E. Schroeder, J. C. Mordough and W. O. Staples. The other incorporation is the Descubridora M. Co., which will work a claim of eighty pertenencias called La Descubridora, adjoining El Oro mine on the south. This mine is said to have the Descubridora, Chihuahua and Calera veins running through it. The officers are J. C. Mordough, J. Devereaux and J. Keeler.

NUEVO LEON.

W. Hauser and A. B. Callender have begun operations on the Santa Catarina mine at El Salado, under lease and bond, says the Monterey News.

OAXACA.

Texas men have begun the exploitation of a group of twenty claims near Zimitlan, near Ayoquesco, 17 miles south of Ocotian.

PUEBLA.

The Altos Hornos Mexicanos Co. at Tepeyahaulco has its first furnace of 200 tons capacity in operation and has started work on a second one. Pig iron, steel rails, structural iron and castings of all kinds are to be made. A. Zevalza is president and E. Segura is manager.

SAN LUIS POTOSI.

The Begona mine at San Pedro, H. Sturgis superintendent, has been leased by the San Luis Potosi smelter, which will improve its workings. A narrow gauge railroad has been completed connecting San Pedro with the smelter's Mesa Verde road, says the Enterprise. The output of the mine is 5000 tons per month of $25 ore.

SONORA.

On the Cerro del Basaitequi, near Arizpe, a large number of locations have been made with the respective pertenencias on veins which give good grades of gold ores. The Adan, Cinco Senores, Don Ramon and Dos Amigos have been sold for $110,000 gold to R. K. Clancy, who proposes to start work on the mines and build reduction works.

The Nogales Copper Co., whose mines are near Magdalena, is preparing to equip a 100-stamp mill.

The La Gran Central copper mines have been sold to C. Y. de Lay and C. F. Kapp of San Francisco, Cal., C. R. Lewis of Oakland, Cal., H. E. Owen of El Paso, Tex., and R. Kirman of Reno, Nev.

It is reported that the Moctezuma Copper Co. will increase their production in Nacozari to thirty-five tons of fine copper per day. The concentrator is running full blast and the ores in the Porvinir tunnel will be handled.

The Cerro Prieto mine, southeast of Magdalena, owned by C. N. Thomas, has a 20-stamp mill in operation. A 100-stamp mill and cyanide plant are proposed. It is claimed that the vein is 70 feet wide. There is a main working tunnel.

ZACATECAS.

A concession, exempting it from taxation for ten years, has been granted the Zacatecas Smelting Co., that is to build a smelter at Zacatecas.

Obituary.

THOMAS CHALMERS, one of the founders of the firm of Fraser & Chalmers of Chicago, died on the 13th inst. Thomas Chalmers was born in Dronley, near Dundee, Scotland, June 14, 1816, and was just entering his eighty-eighth year. His father was William Chalmers, a manufacturer of linen. At the age of 14 he was apprenticed to a Dundee machinery firm to learn the trade of machinist, which he followed in all its branches in Scotland and England for thirteen years. He came to America in 1843. In 1855, with P. W. Gates, E. S. Warner, A. G. Warner and David R. Fraser, Mr. Chalmers formed the firm of Gates, Warner, Chalmers & Fraser, which was succeeded in 1857 by the Eagle Works Manufacturing Co. In the winter of 1871-72 this corporation was dissolved, and with Mr. Fraser, Robert Anthony and David Marchant, Mr. Chalmers formed the firm of Fraser & Chalmers. Two years ago this company, with three others, was merged into the Allis-Chalmers Co., and Mr. Chalmers, Sr., withdrew from active participation in its management.

LUTHER STIERINGER of New York, an electrician of note, died at Pasadena, Cal., on the 17th inst. Mr. Stieringer was the designer of the electrical display at the Pan-American Exposition at Buffalo, N. Y. He was consulting engineer for the General Electrical Co. of New York and patented many well-known electrical appliances. During his stay in California Mr. Stieringer received the John Scott medal, awarded to the man most noted in his achievements in electrical science. He was a member of the Franklin Institute of Pennsylvania for the promotion of mechanical science and of the American Association for the Advancement of Science.

PERSONAL.

G. L. CARR of Carrville, Trinity county, Cal., is in San Francisco, Cal.

ALBERT C. KOCH is manager of the Alta Mines Co. at Telluride, Colo.

G. MITCHELL of Los Angeles, Cal., is in San Francisco, Cal., on mining business.

F. L. BROWN of Brown & Beal, San Francisco, has returned from the East.

S. R. YOUNG, interested in mines near Lovelock, Nev., is in San Francisco, Cal.

W. S. GUFFY of Pittsburg, Pa., interested in oil properties, is in San Francisco, Cal.

S. NEWHOUSE of Salt Lake City, Utah, is at Redstone, near Glenwood Springs, Colo.

C. W. CONKLING of Tekama, Neb., is in Chihuahua, Mexico, on mining business.

M. L. REQUA has returned to San Francisco, Cal., from his copper interests near Ely, Nev.

W. F. BRAY of Placerville, El Dorado county, Cal., is in San Francisco, Cal., on mining business.

J. E. POINDEXTER, interested in mines near Grass Valley, Nevada county, Cal., is in San Francisco, Cal.

CHAS. M. DOBSON, a New York mining engineer, is inspecting mining properties in Shasta county, Cal.

R. S. BAVERSTOCK has returned to Los Angeles, Cal., from an examination of lead mines at Arivaca, Ariz.

R. KELLER, manager of the Emma mine, Dunton, Colo., returned there last week from Denver, Colo.

A. L. ROBINSON of Auburn, Cal., interested in Placer county mines, is in San Francisco, Cal., on business.

M. L. EFFINGER is superintendent of the Wolverine mine at Park City, Utah, vice L. A. Jeffs, resigned.

GEORGE W. LLOYD of Boston, Mass., who has extensive Oregon mining interests, is in San Francisco, Cal.

H. L. WESTLAKE is superintendent of the Coronado mine of the W. B. Thompson M. Co., near Clifton, Ariz.

J. T. MORROW, of Great Falls, Mont., is general manager of the Cananea Con. C. Co., at Cananea, Sonora, Mex.

C. L. SHIRLEY is superintendent of the Aberdeen Copper Co., near Lordsburg, N. M., vice H. N. Bowen, resigned.

PRESIDENT E. L. WHITE of the Bingham Con. M. & S. Co. has returned to Boston, Mass., from Bingham, Utah.

J. H. PRATT of New York, head of the Golden Fissure Co. with mines near Florence, Pinal Co., Ariz., is at the mines.

W. A. HEWITT, president of the Compressed Air Machinery Co., has returned from New York to San Francisco, Cal.

W. E. THORNE, formerly of Georgetown, Cal., has returned from Alaska to develop a California cinnabar deposit.

H. F. BROWN, E. M., has returned to San Francisco, Cal., from mine examinations in the Okanogan country, B. C.

W. A. WILSON returned last week to Salt Lake City, Utah, from examining mining interests in Bagdad district, Cal.

W. C. OREM of Salt Lake City, Utah, manager of the Utah-Apex properties at Bingham, Utah, is visiting in California.

W. L. WATTS, E. M., has returned from San Francisco, Cal., to Los Angeles, Cal., for the purpose of making oil land and mine examinations.

W. G. DODD, president of the Union Iron Works of San Francisco, Cal., is expected to return from New York next week.

J. L. MERY has resigned as mechanical engineer for the United Verde C. Co. at Jerome, Ariz., and is in San Francisco, Cal.

V. C. ALDERSON of Chicago, Ill., has assumed the duties of the presidency of the Colorado School of Mines at Golden, Colo.

C. T. MIXER, superintendent of the Creole and J. I. C. mines at Park City, Utah, returned last week from a business trip to Colorado.

L. C. DOTY, formerly superintendent of the Ely M. & M. Co., at Ely, Nev., is superintendent of the Pilot Knob mines at the same place.

P. S. MERRILL, of Buffalo, N. Y., president of the Log Cabin M. Co., is conducting operations at their properties near Marysvale, Utah.

N. B. KNOX, E. M., of San Francisco, Cal., has been making examinations of copper deposits in the high Sierras in Tulare county, Cal.

PRESIDENT G. W. DAINES of the Belcher mine, near Sumpter, Or., has removed his headquarters from Spokane, Wash., to Sumpter.

W. B. MUCKLOW of Hartford, Conn., president of the Majestic C. Co. at Milford, Utah, is visiting in California after a trip to their mines.

W. KRAFT, part owner of the Descubridora mine (the Goat Ranch mine), near Chihuahua, Mexico, returned last week to Chihuahua from New York.

H. D. SMITH, recently with the Tomboy G. M. Co., Ltd., of Telluride, Colo., is in San Francisco, Cal., from an examination of mines near Butte, Mont.

T. B. COMSTOCK, of Los Angeles, Cal., is consulting engineer of the Carmen Copper Co. of New York, whose properties are in the State of Durango, Mex.

J. B. COPLEN, of Tucson, Ariz., manager of the Pacific M. & M. Co., is at Globe, Ariz., to remain for some time, superintending development work.

J. E. BEVERIDGE has resigned as manager of the Dixie mines and smelter near St. George, Washington county, Utah, to devote his time to personal interests.

L. A. JEFFS has resigned as manager of the Wolverine mine at Park City, Utah, to give his entire attention to operations at Alta, Salt Lake county, Utah.

J. A. CHANSLOR of the Associated Oil Co., and also interested in the Coalinga fields, returned to Bakersfield, Cal., last week from a six weeks' visit in the East.

W. W. HARTS, captain U. S. Corps of Engineers, relieves Captain R. P. Johnston as secretary and disbursing officer of the California Debris Commission, San Francisco, Cal.

C. DOOLITTLE, former superintendent of the Bimetallic smelter of Leadville, Colo., is manager of the Dixie mines and smelter, near St. George, Utah, vice J. E. Beveridge, resigned.

FRANCIS V. GREENE of New York, formerly president of the National Asphalt Co., was in San Francisco, Cal., this week, and has returned east via Ogden, Utah, and Yellowstone Park.

THEO. F. VAN WAGENEN, E. M., who has charge of extensive mining developments at Salisbury, Rhodesia, South Africa, is of the belief that some of the present workings of the Rhodesia Goldfields, Ltd., are on the site of the ancient gold fields of King Solomon and Hiram of Tyre.

G. W. PRICE, for the past eight years manager for the Krogh Mfg. Co. of San Francisco, Cal., has retired from that firm and organized the manufacturing enterprise of G. W. Price & Co. Their principal product will be centrifugal pumps for irrigation and reclamation of land, dredging and draining; also, tailing pumps.

Commercial Paragraphs.

MEESE & GOTTFRIED CO., San Francisco, Cal., are Pacific coast agents for the Link Belt Machinery Co. of Chicago, Ill.

THE Mining Company de Penoles, of the State of Durango, Mexico, is installing four Jeanesville Iron Works electric station pumps for 1000 feet lift.

HENSHAW, BULKLEY & CO. of San Francisco, Cal., report preliminary tests made with the Kinkead mill, being run against five stamps at the Keystone mine, in Amador county, Cal., show thirteen tons of rock crushed per twenty-four hours, using but 3½ H. P.—which equals the guarantee.

Catalogues Received.

The Jeffrey Mfg. Co. of Columbus, O., has issued a handsome catalogue (No. 19) on mining machinery manufactured by them. It describes electrical coal-cutting machinery, boring apparatus, underground locomotives, electrical motors, etc., electric mine pumps, hoists, conveyors, etc. It is handsomely illustrated.

New Patents.

DEWEY, STRONG & CO.'S SCIENTIFIC PRESS PATENT AGENCY, 330 Market St., S. F., has official reports of the following U. S. patents issued to Pacific coast inventors:

FOR THE WEEK ENDING JULY 14, 1903.

733,572.—ROD—C. F. Axelson, Los Angeles, Cal.
733,795.—LOGGING SPOOL—R. Barr, Carrollton, Wash.
733,803.—CHAIR—C. C. Black, Healdsburg, Cal.
733,455.—ELEVATOR CLUTCH—J. A. Bridges, S. F.
733,372.—NIPPLE—F. A. Colwell Oakesdale, Wash.
733,629.—RAFTING DOG—T. H. Curtis, Astoria, Or.
733,463.—OIL BURNER—E. D. Dennison, Stockton, Cal.
733,823.—MITER BOX—R. H. Dorn, Los Angeles, Cal.
733,704.—MAIL BOX—W. G. Dougall, S. F.
733,711.—WATER LEVEL INDICATOR.—Flood, Sayer & Campbell, Spokane, Wash.
733,636.—SHARPENING SAWS—G. A. W. & J. H. L. Folkers, S. F.
733,907.—MINING CAGE—Hanson & Dwight, Los Angeles, Cal.
733,583.—FREIGHT BARGE—L. R. Harvey, S. F.
733,652.—LOCK FOR SIDEWALK ELEVATOR DOORS—P. H. Jackson, S. F.
733,397.—MECHANICAL STOKER—E. W. Jones, Portland, Or.
733,487.—WASHER—E. H. Krebs, Oxnard, Cal.
733,488.—WEATHER STRIP—J. B. A. La Jeuneese, Alameda, Cal.
733,489.—WEATHER STRIP—J. B. A. La Jeunesse, Alameda, Cal.
733,552.—MINER'S CRATE—G. R. MacDonald, Seattle, Wash.
733,730.—BOILER-H. A. Miller, Crockett, Cal.
733,418.—LOADING DEVICE—T. M. Park, Darrington, Wash.
733,740.—GAS GENERATOR—J. S. Philpott, Windeor, Cal.
733,748.—SEWER TRAP—F. W. Rathbun, S. F.
733,749.—DRAG SAW FRAME—E. E. Redfield, Grants Pass, Or.
733,599.—LOOSE LEAF BINDER—W. Saunders, Oakland, Cal.
733,754.—NUT LOCK—P. C. Secor, S. F.
733,683.—FRUIT CARRIER—G. W. Stevens, S. F.
733,882.—PROPELLOR—C. H. Taylor, Seattle, Wash.
733,770.—PIPE WRENCH—J. B. Tupper, S. F.
733,771.—TIN FOILING BOTTLES—Twitchel & Brown, Los Angeles, Cal.
733,444.—CARBURETOR—L. F. Washburne, S. F.
733,449.—BAG HOLDER—B. H. Willisie, Redding, Cal.
733,889.—BABY BUGGY—Susan C. Wolfskill, Winters, Cal.

Notice of Recent Patents.

Among the patents recently obtained through Dewey, Strong & Co.'s SCIENTIFIC PRESS U. S. and Foreign Patent Agency, the following are worthy of special mention:

MAIL BOX.—No. 733,704. July 14, 1903. W. G. Dougall, San Francisco, Cal. Assigned to W. W. Montague & Co., of same place, a corporation of California. This invention is especially designed for the rural delivery and collection of mail matter. It consists in such construction of the box or receptacle with a securing hasp and a signalling target that the box may be locked with the target exposed when there is any mail matter within it to be collected either by the postman or the parties to which it is to be addressed, and in the same connection means for similarly locking the box with the target concealed when there is no mail matter within.

ACETYLENE GAS GENERATOR.—No. 733,740. July 14, 1903. J. S. Philpott, Windsor, Cal. One-half assigned to G. A. Nalley, of same place. This invention relates to an apparatus for the manufacture and storage of acetylene gas and the means for automatically supplying the calcium carbide when necessary and cutting it off at proper intervals. It consists of a generator, a rising and falling gasometer, a reservoir for the carbide movable in unison with the gasometer, a cut-off device and the rising and falling bell and with an exterior stationary point whereby the two operate to actuate the cut-off valve and open it upon the reduction of the supply and descent of the gas holder and to close it and cut off the supply by the ingress of gas and the rise of the gasometer.

LOCKING ATTACHMENT FOR SIDEWALK-ELEVATOR DOORS.—No. 733,652. July 14, 1903. P. H. Jackson, San Francisco, Cal. This invention relates to improvements in locking attachments for doors which are closable upon sidewalks and in like places, and especially used in conjunction with elevators which run between the basement and the sidewalk level. Such doors are usually provided with spring or gravity-actuated latches which operate automatically to lock the doors from within after they are closed and which are retracted to release the doors by the upward movement of the elevator. This invention consists in such a construction of the gravity-actuated latch that they will be retracted by the closing of the doors when the latter are allowed to close without losing the hail.

FRUIT CARRIER.—No. 733,683. July 14, 1903. Geo. W. Stevens, San Francisco, Cal. This invention is designed to provide an automatically adjustable compartment case suited to fruits of different sizes and character, and so that those of the most delicate nature can be safely transported on account of the perfect fit within the compartments and the taking up of any slack between each of the upper and lower series of compartments by reason of the double horizontal diaphragme.

DEVICE FOR SHARPENING SAWS.—No. 733,636. July 14, 1903. G. A. W. & J. H. L. Folkers, San Francisco, Cal. This invention relates to improvements in saw-filing and sharpening machines of the type employing rotary cutters or grinders. The object is to provide a sharpener which may be applied to any ordinary saw and may be held and operated in a uniform relation to the teeth thereof and which shall have its file or grinding members so disposed as to act upon the teeth to best advantage, and without the nerve-racking noise ordinarily accompanying such work.

Latest Market Reports.

SAN FRANCISCO, July 24, 1903.

METALS.

SILVER.—Per oz., Troy: London, 25⅝d (standard ounce, 925 fine); New York, bar silver, 54½c, refined (1000 fine); San Francisco, 54½c; Mexican dollars, 41c San Francisco, 42½c New York.

COPPER.—New York: Standard, $13.50; Lake, 1 to 3 casks, $13.25@13.50; Electrolytic, 1 to 3 casks, $13.62½@13.75; Casting, 1 to 3 casks, $13.00; San Francisco: $14.00. Mill copper plates, $17.00; bars, 18@24c. London: £56 spot per ton.

The copper market shows much weakness and prices are falling. The heavy buyers still defer placing the anticipated large orders and the producers seem unwilling to urge them by cutting prices to a still lower point. The result is an uneasy and bearish market. Production has been stimulated to such a degree by the high price of the past year and the generally low cost of production that this increase in output is now probably being felt in the metal market and somewhat lower prices are anticipated.

LEAD.—New York, $4.30; Salt Lake City, $3.50; St. Louis, $4.00; San Francisco $4.50, carload lots; 4½c 1000 to 4000 lbs.; pipe 5½, sheet 6, bar 5½c; pig, $4.75. London: £11 7s 6d per long ton=2.75c per lb.

SPELTER.—New York, $6.12½; St Louis, $4.85; London, £20 15s per ton; San Francisco, ton lots, 6½c; 100-lb lots, 7c.

ANTIMONY.—New York, Cookson's, 9½c; Hallett's, 8½c; San Francisco, 1000-lb. lots, 10c; 300 to 500 lbs., 11c; 100-lb. lots. 13@15c.

TIN.—New York, pig, $27.25@27.50; San Francisco, ton lots, 29½c; 500 lbs., 30c; 200 lbs., 30½c; less, 31c; bar tin, ℔ lb, 32½c @35c. London, £125 5s spot.

PLATINUM.—San Francisco, crude, $18.00 ℔ oz.; New York, ingot, $19.00 per Troy oz. Platinum ware, 75@80c per gram.

QUICKSILVER.—New York, $44.50@46.00; large lots; London, £8 15s; San Francisco, local, $44.50 ℔ flask of 76½ lbs.; Denver, $49.50. Export, $43.50.

BABBITT METAL.—San Francisco, No. 1, 10c; No. 2, 7c; No. 3, 6½c; extra, 17½c; genuine, 35c; Eclipse, 37½c.

ALUMINUM.—New York, No. 1, 99% pure ingots, 35c; No. 2, 90%, 30c to 34c.

SOLDER.—Half-and-half, 100-lb. lots 19½c; San Francisco, Plumbers', 100-lb lots, 16c.

NICKEL.—New York, 50@60c ℔ lb.; ton lots, 45@48c.

STRUCTURAL MATERIALS.

IRON.—Pittsburg, Bessemer pig, $19.50 @19.85; gray forge, $18 60; San Francisco, bar, 3c ℔ lb., 3½c in small quantities.

STEEL.—Bessemer billets, Pittsburg, $28.00@29.00; open hearth billets, $29.00; San Francisco, bar, 7c to 12c per lb.

LUMBER.—(Retail): Pine, ordinary sizes, $20.00@22.00; extra sizes higher; redwood, $22.00@23.00; lath, 4 feet, $4.25 @4.50; pickets, $19.50; shingles, $2.35 for No. 1 and $2.00 for No. 2; shakes, $13.50 for split and $14.50 for sawed; rustic, $26.00 @32.00.

NAILS.—Per keg (list prices): No. 20d to 60d, Wire, $3.25; Cut, $3.35; 10d to 16d, Wire, $3.35; Cut, $3.35; 8d, Wire, $3.40; Cut, $3.40; 6d and 7d, Wire, $3.50; Cut, $3.50; 4d and 5d, Wire, $3.60; Cut, $3.60; 3d, Wire, $3.75; Cut, $3.75; 2d, Wire, $4.00; Cut, $4.00. Special rates for carload lots.

LIME.—Santa Cruz, $2.25; Roche Harbor, $2.25 per bbl.

CEMENT.—Germania, $2.50 @ 2.75; Hewmoor, $2.90; Trowell, $2.90; Portland, $2.50@2.75 per bbl.

GENERAL SUPPLIES.

POWDER.—F. o. b. San Francisco: No 1. 70% nitro-glycerine, per lb., in carload lots, 15½c; less than one ton, 17½c. No. 1*, 60%, carload lots, 13½c; less than one ton. 15½c. No. 1** 50%, carload lots, 11½c; less than one ton, 13½c. No. 2, 40%, carload lots, 10c; less than one ton, 12c. No. 2 35%, carload lots, 9½c; less than one ton. 11½c. No. 2** 30% carload lots, 9c; less than one ton, 11c. Black blasting powder in carload lots, minimum car 728 kegs, $1.50 per keg; less car lots, $2 per keg.

CAPS.—3x, $5.50 per 1000; 4x, $6.50; 5x, $8; Lion, $9, in lots not less than 1000.

FUSE.—Triple tape, $3.60 per 1000 feet; double tape, $3.00; single tape, $2.65; Hemp, $2.10; Cement No. 2, $3.00; Cement No. 1, $2.65, in lots of 3000 feet and up.

CANDLES.—Granite 6s, 16 oz., 40s., 10½c ℔ set; 14 oz., 40s., 9½c.

CHEMICALS.—Cyanide of potassium, 98%-99%, jobbing, 24@25c ℔ lb.; carloads, 23@24½c; in tins, 35c; soda ash, $2.00 ℔ 100 lbs.; hyposulphite of soda, 2½@2½c ℔ lb.; caustic soda, in drums, 3@3½c ℔ lb; Cal. s. soda, bbls., $1.25@1.50 ℔ 100 lbs.; sks., $1.05; chlorate of potash, 12@13c; nitrate of potash, bbls., 10c; caustic potash, 10c in 40-lb tins; borax concentrated, 7@8c ℔ lb.; roll sulphur, 4@6c; powdered sulphur, 2@3c; flour sulphur, French, 2@3c; alum, $2.00@2.25; California refined, 2@2½c; sulphide of iron, 9c ℔ lb; copper sulphate, 5@7c; chloride of lime, spot, $2.50@2.75; sulphuric acid, in carboys, 66% B, 2½c ℔ lb.; nitric acid, in carboys, 8c ℔ lb.

WHITE LEAD.—Per lb., in kegs: 500 lbs. and over at one purchase, per lb., 6c; less than 500 lbs., per lb., 6½c; in 25-lb. tin pails, ½c per lb. above keg price; in 1 and 5 lb. tin cans, 100 lbs. per case, ½c per lb. above keg price. Dry Lead—In bbls., 1 ton and over, 6c; do. in kegs, 6½c.

RED LEAD.—500 lbs. and over at one purchase, per lb., 6c; less than 500 lbs., 6½c.

LITHARGE.—Pure, in 25-lb. bags, 8 @9c per lb.

BONE ASH.—Extra No. 1, 5@6c per lb. No. 1, 4@5c.

BORAX.—Concentrated, 7@9c per lb powdered, 9@12c; fused, 25@30c.

BORAX.—Crystal, 7c; calcined, 25c.

MANGANESE.—Pure, ℔ lb., 60c.

MOLYBDENUM.—$2 per lb.

CHROMIUM.—(90% and over) per lb., $1.00.

BISMUTH.—Subnitrate, per lb., $1.60.

MERCURY.—Bichloride, ℔ lb., 90c.

PHOSPHORUS.—(American) ℔ lb., 75c.

SILVER.—Chloride, ℔ oz., 90c@$1.00; nitrate, 55c.

ALUMINUM.—No. 1, 99%, small lots, 37c ℔ lb.; 100 lbs., 35c; 1000 lbs., 34c; ton lots and over, 33c, Pittsburg. No. 2, 90%, small lots, 34c; ton lots and over, 31c, Pittsburg.

URANIUM.—Oxide, ℔ lb., $3.50.

ZINC.—Metallic, chemically pure, ℔ lb., 50c; dust, ℔ lb., 10c; sulphate, ℔ lb., .04c.

COAL.—San Francisco, coast, yard prices: Wellington, $8.00; Seattle, $6.50; Coos Bay, $5.50; Southfield, $8.00. Cargo lots, Eastern and foreign: Wallsend, $6.50 Brymbo, $7.50; Pennsylvania, bd., $14.00 Scotch, $8; Cumberland, $12; Cannel, $9.00; Welsh Anthracite, $11.50; Rock Springs, $9.50, long ton; Colorado Anthracite, $14.00. Coke, $10.50 per ton in bulk, $13 in sacks; Sunnyside, $8.50, long ton.

(These prices are wholesale, f. o. b. San Francisco, unless otherwise noted.)

FOR SALE.

FOR SALE.—Good interest in a copper and gold property; 160 acres, near R. R. in California. Large quantity of ore shipped; last shipment 25.45% copper, $9 50 gold and silver. Fine ore supply. One-half purchase price from mine, balance easy cash payments. Fine property for incorporation. Address "Manager," this office.

Tonopah Claims for Sale.

I have several good prospects for sale, located in known mineral belt in Tonopah mining district. Groups suitable for incorporation. Claims $100.00 to $250.00 each. Correspondence solicited.

Address WALTER OSBORN,
BOX 309, TONOPAH, NEVADA.

LILLOOET, FRASER RIVER & CARIBOO GOLD FIELDS, LIMITED.

In Liquidation.

List of Properties to Be Sold by Private Tender, Pursuant to the Directions of the Liquidators.

Trout Lake Mining Division.

ALPHA GROUP (better known as "Broadview Group"), comprising 9 Crown-granted mineral claims, or fractional claims, situated on Great Northern mountain, above Ferguson, B. C., together with two blocks of land, namely: Lot 1144, situated just west of Ferguson townsite, and lot 2949, situated about 2 miles northeasterly from Ferguson on the North Fork of Lardeau river, at the foot of Great Northern mountain.

LANDS situated on Galena Bay, Upper Arrow Lake. Three blocks of land comprising, in all, about 650 acres.

Rossland Camp.

The **"CITY OF SPOKANE"** and **"NORTH STAR"** mineral claims, together with the buildings and equipment thereon.

Boundary District.

The **"NETA"** mineral claim, Crown-granted, situated in what is known as "Brown's Camp," and the **"QUEEN OF SPADES"** mineral claim, Crown-granted, situated in what is known as "Central Camp."

Illecillewaet Mining Division.

The **LANARK GROUP**, comprising 15 Crown-granted mineral claims, or fractional claims, situated on the main line of the Canadian Pacific railway, near Illecillewaet, B. C.

Parties desiring to put in a tender for any one or more of the above mentioned properties should have their engineer on the ground, and examination made, without delay.

Further particulars and conditions of sale and forms of tender (which are to be sent in not later than August 15th, 1903,) may be obtained gratis of the Liquidators, College Hill Chambers, College Hill, London, E. C., and J. V. Armstrong, Revelstoke, British Columbia.

Dated June 15th, 1903. July 31.

SITUATIONS WANTED.

ASSAYER AND CYANIDE MILLMAN DESIRES position. References. Address "Assayer," care of Mining and Scientific Press.

CHEMIST AND ASSAYER DESIRES POSITION in mine or refinery. No objection to foreign countries. Address V.J.H., this office.

FIRST-CLASS MINING AND LAND SURveyor, Draughtsman, etc., desires position. Address H. W. K., Box 74, Long Beach, Wash.

MINE SUPERINTENDENT WANTS POSITION with a substantial company that has a mill on property. A qualified mining engineer who can run a mine or mill, cyanide plant, assaying and surveying. Address "Mining," this office.

MINING ENGINEER AND METALLURGIST, at present general manager of a large mining concern in Mexico, desires to change his position. Would need four months' notice. Address F.B.A.S., care of this office.

HELP WANTED.

Required for Copper Mines in Arizona

employing about 250 men, young mining engineer of good technical education and some experience in mining and mechanics, to act as assistant to superintendent. Address SHANNON COPPER CO., Clifton, Ariz.

WANTED.

CAPABLE ENGINEER OF GOOD STANDING and experience would like to purchase an interest in an established engineering business—mining or civil. Only a business capable of expansion and doing high grade work is desired. Address "Experience," care of Mining and Scientific Press.

WANTED--MILL TAILINGS,

Gold, silver or lead, in New Mexico, Arizona or old Mexico. Will buy or lease. Give location, quantity and value. A. E. VAN VELSAN, Telluride, Colorado. Box 181.

Backing Desired to Look Up Mining Properties.

References exchanged. Address "R", this office.

WANTED—Nitrate of Soda Deposits on the Pacific Coast.

Address "Nitrate," Mining and Scientific Press.

COPPER MINES

Near two railroads; 300-ft. vein; large amount of ore shipped; area ¾ mile by ¾ mile. A good interest will be given for 300 to 500 ft. working shaft, or diamond drill work. Address Agent, this office.

EXCEPTIONAL BARGAIN!

ONE FOUR-FOOT FRUE VANNER, fitted with Brownell Patent Lip Flange Belt. Vanner and Belt absolutely new. Address Fricot & Miller, Latrobe, El Dorado Co., Cal.

MINING AND SCIENTIFIC PRESS.

Whole No. 2245.—VOLUME LXXXVII. Number 5. SAN FRANCISCO, CAL., SATURDAY, AUGUST 1, 1903. THREE DOLLARS PER ANNUM. Single Copies, Ten Cents.

Mining Methods.

Every miner is interested in all that pertains to the practice of his profession. Theories are well enough, and necessary to advancement, but the practical miner desires practical methods—those which have actually been applied and are known to work satisfactorily. He desires methods which may be employed to his advantage, and while the miner is proverbially conservative, and not infrequently too much so, he seldom fails to realize the value of that which operates to his benefit.

In mining practice there is nothing more practical, more necessary nor more important than methods for supporting underground excavations, whether by timbering or filling or by a combination of both. The methods of timbering mines are almost as varied as the numerous types of veins and deposits. Prior to the opening of the Comstock lode in 1860, the excavation of a large stope was always attended with great difficulty and danger, in a country where there was much water or even moisture in the rocks. In desert regions it was not uncommon to excavate large masses with comparative safety, but the average large vein was mined with great attendant danger and the attempt often met with disaster.

The development of the Comstock mines at Virginia City, Nevada, brought to the miner a new and unheard of condition—a vein of what in that day was considered phenomenal width (65 feet), but which seems small when compared with the subsequent development of the "great bonanza" of the Con. Virginia & California on the same lode, which was more than five times as broad in its widest place. The ore in the Ophir mine—rich, but soft and crumbling—was mined with extreme danger. Surrounded by riches, they were unable to extract the ore except at an extreme risk of the lives of the miners.

Out of this anomalous condition the square set method of timbering was evolved, and this has been introduced into great mines throughout the world, proving sufficient for many years, but the demand for still closer economies has rendered various modifications of this excellent and ingenious system imperative.

In the issue of the MINING AND SCIENTIFIC PRESS of July 4 is described briefly the manner of mining in some portions of the Homestake mine in the Black Hills of South Dakota by the method there known as the block system, and it, or some modification of it, is absolutely essential to the stoping of wide veins of low-grade ore in any country where wages are $2.50 to $4 per day. Other methods have been introduced in other countries where no timber at all was used, but labor was to be had at a few cents per day, as, for instance, at Rio Tinto, Spain, where G. D. Del Prat devised a method of mining a large ore body (200 feet wide) without timbering, filling every excavation carefully by hand. This, unfortunately, is not applicable in many places for commercial reasons.

In the issues of July 18th and 25th and in this issue are described mine methods adopted at the Broken Hill mines in New South Wales, Australia. Mr. Del Prat is manager of a large mine on that great lode, but he finds it inexpedient to apply the methods of Spain to the mines of Australia. The "block system" as practiced at Broken Hill, while similar to that at the Homestake, seems to possess some features which are superior to those of the latter, particularly where the square set is used as a lining, as it were, to the ends of the blocks, there being no timber at all in the center of the stope.

By this ingenious system good ventilation is secured; the breaking and handling of ore is reduced to a minimum; the miners are as safe as they could be in any large mine; the danger of knocking down several sets of timbers previously placed is practically averted, and it leaves the alternate blocks standing in such shape that they may be safely and economically extracted at any subsequent time.

Unfortunately, this open timberless method of stoping can only be employed in those mines having a fairly good, sound back. Where the back is treacherous the full square set should be employed, and the filling kept well up to the back. By the latter system, in very bad ground it would seem advisable to reduce the width of a stope block from 50 feet, as at Broken Hill, or 60 feet, as at the Homestake, to 40 feet, or even 30 feet. This narrower width will facilitate the disposal of the ore by shoveling into the mill holes at the ends of the stope. If the back is good or fairly so, and the 50 or 60-foot block is decided upon, it would appear that it would be economy to provide a center line of mill holes, which would render it unnecessary for shovelers to throw rock more than 15 feet to any mill hole.

The March of Progress.

The successful solution of difficult engineering problems, which is so pronounced a feature of modern progress, illustrates, better than anything else, perhaps, the need of a thorough education, without which the young man and youth of to-day will be out of the race in the very near future. Unusual problems are met daily in the ordinary course of mining and metallurgical business. Problems in engineering, in metallurgy, in chemistry and physics are being solved by young men with complete technical education. The rapid onward march of scientific progress is led by men of this character. Old methods, time-honored and trusted, are overthrown to make place for innovations in every department of science. Success overcomes failure or mediocre accomplishment, and the world is being educated so rapidly that one is bewildered in the effort to keep up with the swift moving procession of achievement. That which was good enough a decade ago is no longer given a place in this onward march, where a better method has been discovered. There are few of the modern scientific discoveries that are the outcome of chance. They are mostly the result of long and careful research, pursued intelligently and persistently, until success rewards the effort of painstaking, methodical inquiry. It is the scientific man who is leading the world to-day, and his value as the most important factor in our commercial and mechanical success is rapidly being realized and substantially recognized.

CHINESE are still seriously talked of for the mines of the Rand in South Africa, although there is much opposition to them by merchants and white miners. Mexico, it is said, also contemplates the introduction of Oriental labor in the mines of that republic, for the reason that an insufficient number of Mexican miners is obtainable. It is more than probable that any actual attempt to carry out the idea in either Mexico or South Africa would meet with opposition of a sort difficult to overcome.

Economies in Mining.

The average mine superintendent or manager is anxious to make a record as a successful manager. In some—in most—instances success is synonymous with economy. A noted Western mine owner and manager is quoted as saying, "D——n a mine that won't pay with any kind of management," but this was said at a time when only good—that is, rich—mines could be made to pay, and the experience of this man chanced to be largely with noted and rich mines. Such sentiment is given less attention in these later days, when there are many mines being profitably worked under good management, which would prove a losing proposition in the hands of an inexperienced or extravagant manager.

One of the principal factors in the success of a mine manager who has charge of a low-grade property, where the margin between profit and loss is very small, is the ability to make use of every natural advantage, and to so equip the property in every branch that the greatest possible economy in labor will result. A careful miner will develop his pay shoot before undertaking the expense of running long tunnels or sinking shafts through hard rock, for the further development or exploitation of these ore bodies. But often it is determined by mine owners to do extensive exploratory work, on the strength of valuable developments in adjoining property. If the work it has been decided to undertake be of considerable magnitude, it is desirable to have it accomplished as expeditiously and as inexpensively as possible. If a long tunnel is to be driven, a compressed air plant and machine drills are advisable, and the wise manager will at once provide these, for he knows that time, and therefore money, will be saved by the investment. He will work all the men in a shaft, or elsewhere, that he can employ to advantage, thereby reducing superintendence and general office expenses. He will buy first-class supplies in large quantities, securing the lowest market prices and discounts, and the transportation problem will be given the necessary consideration.

Wherever machinery can be utilized to advantage it is given a place, cheapening the cost by reduction of labor. Ore is sent on wire ropeways or in trainloads, hauled by motors or animals, in place of in single cars trammed by men. If the construction of a tramway is justified by the amount of material to be moved over it, the tramway is built. If a small mill is overcrowded with ore, additional crushing facilities are provided. The rock breakers are set at a point intermediate between the hoist and the mill, so that all crushed rock may be distributed evenly throughout the mill, and not the coarse in one place and the fines in another. This method also economizes labor—something which should never be lost sight of. The entire plant is arranged to operate automatically, by gravity. No longer is the rock breaker placed above the floor in order that the breaker man may get the proper amount of exercise on his shift in shoveling the ore into the jaws of the crusher, and the day of the hand battery feeder has for most part passed away.

All these things the mine manager can anticipate and provide for, but he is not omnipresent and cannot give continuous personal supervision to each of the several departments under his care. It is a physical impossibility for such a man to plan, execute and give individual scrutiny to each and every detail. He must possess judgment of men, and, having this indispensable quality, will surround himself with a corps of lieutenants each a specialist in his department. Make each of these accountable to the manager, and, if his men are well chosen, the result will probably be the best that can be accomplished under existing conditions, whether it be a profitable one or not. There are, however, times when the mine manager must have rare judgment, and that is in the introduction of innovations—untried schemes for beneficiating ores and other similar propositions involving expense and uncertainty of the result. On the face of it the new venture generally promises success, but many have discovered to their cost—or the cost of their company—that "things are not always what they seem."

The manager who always waits for his neighbors to do the experimenting is overconservative, and if all were thus inclined the steps of progress would be slow and hesitating, but one can usually approach contemplated changes of this character with a degree of caution which, while giving a fair trial, in the event of failure will not bankrupt the company. If a change of ore treatment be deemed advisable, experiments can be conducted in a conservative manner and the results made positive on a limited scale before throwing out the old plant and establishing the new.

Tests made on small quantities of ore—a few ounces—in the laboratory may not work in an equally satisfactory manner on a large commercial scale, consequently experiments of this character must be on quantities sufficiently large to demonstrate the adaptation of the process chemically, mechanically and commercially. Instances have not been lacking in the past where large mills or smelters have been built when there was no ore in the mine, or at least none valuable enough to be treated by any known process, and such instances are not of infrequent occurrence still, but it is safe to say that none of these installations were made under the direction of a competent and experienced, honest manager.

Evolution of Metallurgy in Butte, Montana.

No more interesting page in the history of mining in the West can be found, perhaps, than that furnished by the upbuilding of the industry at Butte, Mont. Elsewhere herein will be found the first of a series of chapters on the evolution of the metallurgical practice at Butte, by H. O. Hofman, in the Transactions of the American Institute of Mining Engineers. It indicates the changing situation in the copper camp from year to year, and also is a fair index of the character of the men who have had the direction of affairs in Butte. Any installation, no matter how expensive and how successful it proved to be in the handling of the ores of the district, was quickly discarded for another which was shown to be capable of accomplishing more and better work for less money. Whole plants, costing hundreds of thousands of dollars, were closed down and abandoned for newer and better ones. To effect a stricter and more rigid economy became—and, in fact, still is—the constant aim of the Butte mine manager. In the production of gold the only competition is found in the struggle against unnecessarily excessive cost. The product has a standard valuation, no matter at what cost it may have been produced, but in the production of copper each mine is in competition with every other copper mine in the world, for all eventually reach the same market and prices fluctuate with supply and demand. A great copper mine which could pay dividends on 15-cent copper might not be able to make a profit on 12-cent copper, and should the price drop the expense of production must be reduced as far as possible to meet the drop in price.

To effect this often necessitated a complete change in metallurgical methods, and the consequent expense of large sums of money. A parsimonious policy would be an unwise one to pursue in Butte, as it is anywhere, for the manager who hesitated to take advantage of a new discovery in treatment of ores or an improvement in furnaces soon found himself handicapped by the more economical production of his neighbors. Although these changes have been taking place for nearly a quarter of a century in the Butte district, it is unlikely that the last radical changes have been made, and other and surprising innovations in that district may still be anticipated.

IN Philadelphia the "scientist" has appeared who has at last discovered the long sought secret of making gold, at least, so he says. He claims to have discovered that the only material difference between gold and silver is that gold contains twice as many ions as silver. He has managed, he declares, to separate these ions of silver and reunite them as gold. The financial world has not, as yet, given evidence of great alarm over the possibility of overproduction of gold due to the latest fake discovery.

WHERE workmen of any class receive the same wage rate, irrespective of ability, the poorest worker sets the pace for all the rest, and the good man naturally degenerates, while the poor one does not advance under such a pernicious system.

CONCENTRATES.

A CUBIC FOOT of steam shrinks upon being condensed to about 1 cubic inch of water.

♣

IN a steam engine the "lead" means the amount of steam port opening at the end of the stroke of the piston at either end of the cylinder.

♣

A GASKET on a steam joint can be made easily removable when necessary by rubbing a little graphite and oil on both gasket and metal surfaces.

♣

THE practice of burning tin mill screens before using is not universal, but is recommended, as it anneals the iron and removes the likelihood of the tin amalgamating.

♣

IT IS desirable and advisable to save all the gold in an ore that can be economically saved, but there is a limit to which this can be carried, and the operation still remain a commercial success.

♣

IN substituting a steel hoisting rope for one of iron, the object should be to secure increased service, and, consequently, lower cost per ton hoisted, rather than to decrease the size of the rope.

♣

LATITE is a name employed to indicate a family of rocks intermediate between the andesites and trachytes. These rocks contain both orthoclase and plagioclase, also augite, hornblende, biotite and olivine.

♣

ONE HUNDRED DOLLARS' worth of assessment work is required on placer claims as well as on quartz claims, although the Federal law does not explicitly say so. Both the courts and the Land Department have announced this ruling.

♣

NO AMOUNT of water to be employed in a stamp battery can be stated, as this amount varies much with the character of the ore; but it may be said that it is best to use as little water as will accomplish proper amalgamation and keep the battery and plates clear.

♣

GOLD AMALGAM will usually retort about one-third of its weight in gold if tightly squeezed; but it varies considerably with the fineness of the gold. Ore producing coarse gold gives usually a high-grade amalgam. In ores where the gold is very fine the amalgam runs down to 16% to 20%.

♣

WYOMINGITE is a name that has been suggested for an unusual variety of igneous rock occurring in the Lucite hills in Wyoming. It is largely made up of the mineral lucite and the variety of mica known as phlogophite, with some apatite and subsidiary minerals. This rock is related to the phonolites.

♣

THERE is, unfortunately, no standard of size in shoes and dies of given weight. The difference is usually found in the dimensions of the shank of the shoe which extends upward into the boss head. These vary in height, width and slope angle. There is no reason why there should not be a standard of size for these mill supplies.

♣

WITH increasing altitude, the boiling point of water becomes increasingly lower. Heights can be measured with approximate accuracy by means of an instrument known as the boiling-point thermometer. A table giving the various heights indicated by the temperature of the boiling water is employed in connection with this test.

♣

GASH VEINS are those which seem to be the result of shrinkage of rocks at the surface, and subsequently filled with quartz. They are usually of comparatively short length and shallow depth. They are thought by some to represent isolated lenses of quartz in the formation, which have subsequently been exposed at the surface by erosion.

♣

THE cost of producing a pound of copper varies greatly at the same mine, depending upon the grade and character of the ore. This cost can only be obtained by taking the average expense for a long period—say a year. On ore of the same general character and grade the cost will vary with the difference in situation, magnitude of operations, etc.

♣

WHERE it is desired to employ water power and a large volume is easily obtainable under comparatively low head, a turbine wheel will be found efficient. High heads and less volume are usually sought, but not always readily obtainable. The relative cost of installation depends entirely upon the surroundings, character of stream and other factors.

♣

THE hammer test for boilers is considered superior to the hydraulic or compressed air test, as in the latter the boiler may be strained and upon heating a leak may result. The hammer makes it possible to detect the difference between a flawless and an imperfect sheet, by the sound, and every portion of the boiler can be tested by this means separately. When boilers are tested by hydraulic pressure this pressure should be at least 50% greater than the steam pressure. Thus, if the steam pressure is to be 100 pounds, the hydraulic pressure applied should be 150 pounds per square inch.

♣

IT is desirable where tailings are treated from the stamp mill direct, that they shall be exposed to oxidation as little as possible; particularly is this the case with ores carrying sulphides of copper and iron. The oxidation or semi-oxidation of sulphides produces sulphates and free acid which must be washed out or neutralized with alkalies before cyaniding.

♣

A DYNAMO which is so constructed that the entire current passes through the field coils is called a "series" dynamo, and where an additional external circuit is provided, so that only a portion of the current passes through the field coils, this outside parallel connection is called a "shunt," and the fields are said to be "wound in shunt" with the outside circuit.

♣

STEAM STAMPS weighing 1600 pounds, with rapid drop (126 per minute), have recently been tried on the Rand, South Africa, but were not satisfactory. They are to be replaced with gravity stamps. The endeavor was made to crush nine tons per stamp. The steam stamps were 11 inches in diameter and 20 inches high, and the stems 5 inches diameter.

♣

THE term "lacoolite" was introduced by G. K. Gilbert for those intrusive masses of igneous rock that, coming from below, spread out in flat sheets between layers of sedimentary rock which they penetrate, and do not reach the surface unless exposed by subsequent erosion. It was the result of his exploration of the Henry mountains in southern Utah.

♣

MANILLA ropes for mine hoists are in very limited use, having been replaced by steel. In a few small mines where the acid waters rapidly corroded iron ropes, manilla or hemp ropes have been substituted for iron. One of these is at the Newton copper mine, Amador county, Cal. It is unlikely, however, that such ropes are more economical than modern steel ropes.

♣

THE strike of the gold-bearing conglomerates on the Witwatersrand is approximately east-west and the dip south. There are no extralateral rights, and the superficial area of a claim or group of claims determines the extent of the underground holding. This varies in relation to the angle of dip. The steeper the dip the greater the amount of banket under a given surface area.

♣

THE atmospheric temperature in the Coolgardie district of Western Australia is sometimes so high that only about 20% of the steam of the engines will condense in the surface condensers, which makes steam making expensive in that section. The shortage of water has been overcome by the extensive pipe line and pumping plant recently put in there from the vicinity of the coast to the mines.

♣

GOLD is yellow by reflected light and green by transmitted light. If the gold be alloyed with silver the color by transmitted light is light green, and if with copper, emerald green or even bluish green. When in a fused state gold presents a peculiar greenish color, and at increased temperature emits purple vapors. There is always a certain loss when gold is highly heated, due to vaporization.

♣

THE word "tiff" is of Cornish origin, and was a name originally applied to fluorspar, but by common usage this application has been extended to embrace other spars, until now "tiff" means any kind of spar, though in Missouri lead-zinc mines it is applied to the particular spar which chances to be most abundant in any particular district. This includes calcite, fluorspar, heavy spar, celestite, strontianite and witherite.

♣

THE difference between a high pressure and low pressure engine is that in the former the steam pressure is over forty pounds per square inch and the steam exhausts into the atmosphere, and in the low pressure engine the steam pressure is below forty pounds and the steam exhausts into a coodenser. The condenser accumulates a quantity of hot water, which can be reused in the boiler, and maintains a constant vacuum in front of the piston, which assists in moving the piston to the amount of about one-half the vacuum gauge pressure.

♣

IN running ropes the wear of the rope increases with the speed, in consideration of which it is advisable to increase the load carried rather than the speed. A hoisting rope should never be required to carry over one-sixth of its capacity at its worst—that is, when the rope is worn out and considered unsafe. It is not the constant weight of the load when running that severely tries the rope, but the sudden starting and stopping. The loaded skip or cage should never be started with a jerk, but slowly and with increasing speed until the maximum has been reached.

♣

THE efficiency of compressed air in operating pumps underground in mines is greatly increased by reheating the air at a point near the pumps. This is usually possible where the ventilation is sufficiently good. A compound direct-acting pump, heated sufficiently to prevent freezing, will pump double the amount of water with the use of a given amount of air that a single-acting pump will. Freezing of a mine pump may often be prevented by arranging a drip from a pipe so that a small stream of mine water will fall upon the exhaust opening. This usually keeps the temperature at a point somewhat above freezing. A large exhaust opening is also necessary, and may be kept from clogging with ice much easier than a small one.

♣

WHERE a steam pump is used in a shaft a slip joint is of great service both on the steam and column pipes. In placing these in position arrange them with the smaller pipe uppermost, otherwise grit, being forced upward in the column pipe, will settle around the smaller inside pipe and bind it so tight that the pipe can be drawn neither up nor down. Should this occur as the result of inexperience, the grit may be removed by disconnecting the pipes and loosening the grit by pounding on the outside of the pipe. The removal of the grit may be facilitated by the use of a stream of water under pressure, directed into the larger pipe.

♣

A MINING CLAIM located late in the summer of 1902 has until midnight Dec. 31, 1903, before reverting to the public domain if assessment work has remained unperformed. In California the miner is chiefly to be guided by the Federal statutes, as there is little State legislation of importance. Recording of mining locations is not required by the United States statutes, and is only necessary where the State or local laws make it imperative, and this California laws do not require. However, the miner should surround his claim with every possible safeguard, if it is of any promise, for should a valuable mine be developed, the title should be perfect, and the more valuable the property the greater the necessity for every precaution to make the title secure.

♣

MAGNESITE—magnesium carbonate ($MgCO_3$)—frequently contains a small quantity of magnesium silicate, and sometimes iron carbonate. Its massive form is similar in appearance to unglazed porcelain and is rather hard to drill, though brittle. Magnesite in its crude state is used in the manufacture of carbon-dioxide gas, either by calcining or by treatment with sulphuric acid. In the latter case, the magnesium sulphate, as a by-product, is crystallized out, yielding Epsom salts ($MgSO_4\ 7H_2O$). The residue, after calcining (MgO), is used as a refractory lining for open-hearth furnaces and converters, either in the form of bricks or concrete; it is also mixed with asbestos as a non-conducting covering for steam pipes, boilers, etc.

♣

THE Bruckner roasting furnace is a cylinder of plate iron revolving horizontally on friction rollers between a flue and a fire box. The ore is charged and discharged through manholes in the side of the cylinder. The flame from the fire box passes directly through the furnace, and thence mixed with the gases from the roasting ore passes to a dust chamber. The Bruckner is an intermittent furnace. One charge must be removed from the furnace before another is introduced. The White-Howell furnace is also cylindrical in form, revolving horizontally on friction wheels or carriers between the fire box and the flue, but this type of furnace is continuous in operation, the ore entering at one end and discharging at the other, the flames traveling in a direction opposite to the travel of the ore. The furnace is inclined slightly toward the discharge end.

♣

THE demand for metallic bismuth is considerably exceeded by the supply. The production and price of bismuth and its ores are under control of Johnson, Matthey & Co. of London, England, and the government of Saxony—as the output must be restricted in order to make it profitable to work the mines. Bismuth is found in several districts of the western United States, occurring both free and combined. A telluride and tellurate of bismuth have been found in Colorado. Gold and silver values are also frequently associated. The principal use for the metal is in the manufacture of alloys which melt at comparatively low temperatures—lead, tin and cadmium being the other constituents. An alloy of 50% Bi, 27% Pb, 4% Sn and 3% Cd melts at 60° Centigrade. Bismuth is also a constituent of anti-friction alloys, pewter and type metal. Bismuth subnitrate—$BiNO_3(OH)_2$—is used in medicine and as a cosmetic.

♣

HEMATITE (iron sesquioxide) Fe_2O_3, contains iron 70%, oxygen 30%. It is of several varieties. Specular iron is a micaceous variety, with metallic luster, the crystals often splendent, coarse to fine grained, the latter often resembling some kind of mica schist. It is soft and unctuous to the touch, has a red streak, compact columnar, or fibrous, is often hard—5.5 to 6.5—luster sub-metallic, the masses often radiating, color red, brown, brownish black; sometimes found in reniform masses called "kidney ore," streak red. A third variety is red and earthy, being soft, readily soiling the hands. Reddle and red chalk are earthy varieties of hematite, with some clay. Clay iron stone, common in silver and gold mines and elsewhere, is hard, brownish black to reddish brown, sometimes deep red. Its luster is submetallic to unmetallic. This ore is often siliceous or clayey. When associated with lead carbonate it forms the so-called "hard carbonate" found in Leadville, Colo., and other lead-silver mines. Limonite is the brown variety of hematite. Limonite, if highly heated, parts with its water of crystallization, and turning red becomes hematite.

The Guadaloupe y Calvo District, Chihuahua, Mexico.

NUMBER III

Written for the MINING AND SCIENTIFIC PRESS by H. Z. OSBORNE.

The Guadaloupe y Calvo mining district embraces the southwestern corner of the State of Chihuahua, Mexico, where that State joins the States of Durango and Sinaloa. A Mexican mining district is a rather important political division, and frequently embraces a large extent of territory. All mining claims, or "denouncements," within its boundaries, must be filed with the mining agent for record, at its capital, as well as all other official or legal papers affecting mining titles. The town of Guadaloupe y Calvo is the capital of the mining district of that name, as well as being the largest town in that section. Its elevation above sea level is 7300 feet. It is connected with the outside world by trails east across the Sierra Madres to Parral, and west to the Pacific coast. Most of its commercial supplies come from the East, but a portion comes from Mazatlan. In a former paper the writer described the trip from Parral to Guadaloupe y Calvo, and gave a brief description of the latter town. The two principal mines at Guadaloupe y Calvo are the Rosario and the Independencia, the former being the larger, and having had an interesting history. Walter Harvey Weed, of the U. S. Geological Survey, has visited this section, and contributed two interesting papers on its geology and mines to the American Institute of Mining Engineers. Of the geology of Guadaloupe y Calvo Mr. Weed says:

"The gold occurs in fissure veins traversing altered and fractured andesitic rocks. These quartz veins are older than the rhyolitic rocks, and only show where the light-colored, chalky-white or pink porphyry tuffs have been removed by erosion or mine workings. In part the ores occur in andesitic gangue, but more commonly in true quartz veins. The amorphous or crypto-crystalline nature of some of the quartz suggests replacement, but 'comb quartz' also occurs. The veins are only exposed on the east side of the creek, the west slope being composed of dacitic rocks."

The Rosario mine has been under bond to C. W. Clark, a son of W. A. Clark of Montana, for two years, and it was recently purchased by Mr. Clark for $500,000. During the visit of the writer in February, 1903, the 10-stamp mill was in operation on ore, most of which was sorted from the old dumps, which are very extensive. An accompanying illustration shows the mill and the croppings of the vein. Of the Rosario vein Mr. Weed says:

"This vein is one of the largest producing quartz veins of the world. It varies from 60 to 150 feet in width, and dips with the hillside so that it forms a great reef fronting the valley, and its exposed wall forms a very conspicuous object. It is said to average over 100 feet across, and where I measured it the thickness was 110 feet. The great open cut on the vein is 1800 feet long, 7 feet deep and 130 feet across. Four distinct ore shoots, separated by low-grade quartz, have been worked. The low-grade ore now forms the enormous dump heaps seen at the mine; and, despite the fact that the people of the town have largely obtained a living by picking over this dump, it is said to be all good cyaniding ore, 'averaging better than $10 per ton.' The vein has a N. W. - S. E. course, and dips west. The vein has been worked on one hill to a depth of 430 feet, but a vein of this magnitude will probably not play out at such shallow depths.

"The Rosario vein was discovered in October, 1835, by a Tarahumar Indian from Nobogarne, when it was shown to some miners from the Refugio mine, 30 miles south of Rosario. The extraordinary size and richness of the vein caused a rapid influx of miners to the locality, and two months after the discovery there were 2000 people encamped about it. The vein was located by various individuals, but soon passed, by purchase and debt of the owners, into the hands of the Ochoa family. In 1836 the Ochoas leased the property, in two parcels, to two companies, organized with English capital, and known as the Guadalupe Co. and the Zorilla Co., respectively. The Guadalupe Co. worked the western part and the Zorilla the eastern part of the property. These companies were obliged to work under lease, as the former Mexican law did not permit foreigners to hold real estate. The terms of these leases are said to be in the mining records, and provided for a royalty of 25% for four years and $50,000 for eight years; the lease expired in 1847 or 1848.

"Under these companies the vein yielded largely of gold and silver, so that in October, 1842, a decree was secured from the Government permitting the erection of a mint at the mine. The records of this mint have been destroyed by fire, but custom house records show that coinage began in July, 1844, and that steam power was introduced in 1847.

"The recorded output of the Rosario for the years 1838 to 1846 is $16,000,000, but owing to the heavy tax upon bullion and the ease with which the tax was evaded, reliable estimates place the total output from the discovery of the vein to the closing down in 1847 at $40,000,000. The mine was, during these years, worked by the most primitive methods, and the tailings show that a large part of the value was lost. The ore was carried on men's backs to the surface and then packed on burros to the various crude reduction works located many miles down the creek, where it was treated in tahonas, with an overshot water wheel furnishing the power.

"In 1847 large quantities of water were encountered; and, the working expenses being very greatly increased, the English companies attempted to renew the lease for a rental of $30,000 a year, a proposal that was indignantly refused by the owners. Personal differences, added to the refusal, led to the abandonment of the property by the English company, who removed to the silver mines of Guanacevi. From this time to 1883 no development work was done. Various Mexican miners robbed the pillars of rich ore left in the workings, 'gophered' the rich streaks of ore, and sorted the dump.

"In 1883, Judge Flipper, representing the Guadalupe M. & M. Co., organized at Memphis, Tennessee, secured the property under an agreement with the Ochoa family, who reserved a one-fifth interest and were to receive one-fifth of the gross output of the mine. This company operated the mine until 1887—erecting a 10-stamp mill, and sinking a new shaft, from which a crosscut was driven to the vein and drifts run out from the old shafts. In one year this company shipped $113,000 in gold; but the manager was robbed of nearly $20,000 while taking the bullion across the mountains, and, as a consequence, the property was abandoned by the company in 1887 and reverted to the Ochoas. At that time the Mexican mining laws required properties to be worked by six men for six months of each year; this the Ochoas failed to do, and in 1889 the property was denounced by four Americans, who obtained title from the Federal Government. With three Mexican merchants, admitted as equal partners, the property was operated and the ore treated in a stamp mill with pan amalgamation. In 1892, operating under lease, two of the partners cleared over $100,000 in twenty-two months, working on ore from the dump heap and from the rich pillars left in the workings. Meanwhile the ownership of the property passed into the hands of Tibuceo Garcia, and was sold by him in 1895 to the Rosario Mining & Milling Co."

Such is the history of the Rosario mine to the present day. It will now doubtless enter upon a new era of development at depth. The present workings are several hundred feet deep. No doubt a powerful hoisting plant with big pumps and a large mill will be put on the property. The lack of roads will make this expensive, and possibly the new owners will find it economical to make a wagon road to the terminus of the Parral & Durango railroad, over which to carry their machinery. An extension of that road to Guadaloupe y Calvo is possible, and if constructed it would open up a rich mineral country.

The Independencia property is the second one of importance at Guadaloupe y Calvo. Of this mine Mr. Weed says:

"The Independencia property includes a group of claims situated east of the town of Guadaloupe y Calvo. The claims cover a complexity of veins. The main workings are entered by a tunnel near the mill, and include shafts and drifts on the Independencia ledge. The vein outcrop consists of porous white quartz, which is rusty and drusy in some places. The ledge runs a little north of west, and has been quarried by open cut and stoping from below. These workings show the vein to be 8 or 10 feet wide, with a pay streak from 1 to 5 feet across, showing a well-defined sinuous wall. The ore consists of white quartz and red jasperoid carrying pyrites, and rarely free gold. Some of the ore carries high values in silver, but no recognizable silver minerals were seen, the richest ore showing a black clouding of the quartz. The vein filling is finely crystalline, and shows none of the coarse texture and comb-structure of a filled fissure, its nature being that of replacement quartz. Where crystalline quartz is seen, it is secondary, and cements fragments of shattered original vein filling. A banded structure is rarely seen, and occasionally the vein filling shows fragments of an andesitic breccia, the rock being altered and of a greenish-yellow color. So far as seen, the vein is nearly vertical. Its surface continuity is interrupted by a patch of rhyolitic tuff.

"The workings consist of three tunnels with drifts, and expose the vein for a vertical depth of 220 feet; two winzes of 26 and 30 feet depth, respectively, prove the vein below the lower tunnel. The following assays show the general character of the ore on the Cuauhtemoc vein: Gold, 0.04 oz. to 5 oz. per ton; silver, 3.20 oz. to 167 oz. per ton. An average of twenty-four assays from the various faces gave: Gold, 1.18 oz. per ton; silver, 16.62 oz. per ton. The ore varies in appearance. The pyritic ore is commonly reddish quartz, with veinlets of white and gray quartz. The silver ore contains finely disseminated galena, with zinc blende, and occurs in a mixture of dark gray, white and amethystine quartz. Chalcopyrite occurs in minute specks. The rich gold ore shows dull greenish secondary quartz, often in botryoidal forms, filling cavities; the primary ore often shows rusty gold, suggesting decomposed telluride ores. It also occurs associated with minute specks of copper pyrite and zinc blende. The rocks are altered porphyritic andesites."

Leaving Guadaloupe y Calvo and proceeding westerly, one passes down the bed of the arroyo, the water of which is used for the Rosario mill. The ruins of a good many old reduction works, generally tahonas, or arrastras, are seen, which were run by the English company, or later by gambusinos. These ruins of old works, the buildings generally of stone, are seen along the streams for considerable distances beyond Guadaloupe y Calvo, where it is said the Englishmen used to pack their ore from the Rosario.

A sugar-loaf mountain is a conspicuous object on the landscape west of Guadaloupe y Calvo—thirteen hours ride distant. Indeed, it can be seen two days before reaching that place, from the heights east of the Rio Verde. It is called Mount Milpillas. After leaving Guadaloupe y Calvo the mineralization of the country does not seem so marked before reaching this mountain as it does after it is passed. From Guadaloupe y Calvo the Arroyo Santa Rosalia is five

Open Workings and Tunnel, Rosario Mine, Guadaloupe y Calvo, Mexico.

Mala Noche, an American Home in Mexico.

hours' ride, Arroyo Hondo (deep) is two hours farther, and Los Tarros, in the saddle right under Mount Milpillas and north of it, six hours farther. Los Tarros is at an elevation of 8850 feet. Between Arroyo Hondo and Los Tarros are La Reforma plantations, embracing several thousand acres planted mainly in corn. Plowing was in progress at the time I passed, and it was interesting to observe the Indians manipulating the primitive plows, consisting of a sharpened stick attached to a pole, in turn fastened to the horns of oxen. A dozen or more teams were being worked in one field.

(TO BE CONTINUED.)

The Kayak Coal and Oil Fields of Alaska.

Written for the MINING AND SCIENTIFIC PRESS by P. C. STOESS.

The Kayak district occupies a belt of country extending along the Alaskan coast for a distance of 175 miles from the west side of the Malaspina glacier on its far eastern end to the waters of Prince William sound on the west, being bounded on the north by the high ridge forming the main St. Elias range of mountains, thence south to the tidewaters of the Gulf of Alaska, 30 to 40 miles.

An area, nearly in the center of the belt, 40 miles wide and running from the summit of the St. Elias range to within 2 to 5 miles of tidewater, is taken up by the Behring glacier. The strip in front of the glacier, between it and the gulf, is a gravel moraine for the most part, covered in places with scrub timber, and through which several streams flow from beneath the glacier, varying much in their courses at different seasons.

The country shows a number of low abrupt hills, separated from each other by flat wide valleys, having easy grades and fronted in places on the shore line with level tidewater and mud flats. The tops of the hills are bare, rocky and precipitous generally, the foothills are covered with a fair growth of spruce timber, and the valleys with a thick growth of alder, berry bushes and grass, with, in places, good soil. The moss, usually found in Alaska, is in this section not over 6 inches to 1 foot thick.

The climate is not as severe as that of the interior, but the rain and snowfall are much greater. The climatic conditions are about the same generally as those prevailing on the coast section of Alaska, and there is nothing in the climate to prevent active operations in the way of development the year round, when the conditions are provided for.

The formations consist generally of a series of coal-bearing sandstones, the croppings of which are 15 to 20 miles inland, ranging from gray to reddish-brown in color, and overlying a series of oil-bearing shales and slates, cropping on the beach and shore line and in the low hills bordering the coast.

The thickness of these formations is not known, but from the indications so far as observed the coal measures are not less than 7000 feet thick, while the oil shales appear to have an equal thickness. In the section of country around Catalla the formation is considerably broken, the rock dipping in several directions, within a small area. The general course of the hills and the strike, however, in this part of the fields is north and northeast, the dip varying from vertical to 40° to the northwest. About 15 miles inland, in the area of the coal croppings, the formation is less disturbed and the strike swings off more to the east. In the coal croppings on Carbon, Clear and Canyon creeks it strikes east-west and dips 40° to 60° north. East of the area covered by the Behring glacier, in the Yaktag section, the formation is less disturbed and has a course nearly east-west and dips 35° south. The section to the west of Catalla, west of Martin river, is covered by the immense tide flats of the Copper river delta, subject to inundation by both tidewater and the floods of Copper river, while further west, around the Eyak-Orca section, the country is broken and generally more like the region around Catalla.

Oil seepages of importance are reported on and near the shore line of this entire belt. Extensive gas flows have also been found associated with oil seepages, and in places where no oil has been discovered. The principal oil seepages found are on Johnson creek, White river, Yaktag and Ducktaw rivers in the Yaktag district, up Eight-Mile river, and at the head of the Ochtilee river in the Sucklin district, 3 miles up the south fork of the Neuchawak river, near the head of the Catalla slough, at the head of Martin slough, in the Catalla district, and near and on the south end of Eyak lake in the Orca district.

Beside these there are numerous less important ones. A hot sulphur spring has been found on the southeast end of Eyak lake. It has been stated that the oil-bearing belt does not extend anywhere more than 5 miles inland from tidewater, though gas flows and signs of oil have been found as far inland as Kostakra lake, 5 miles farther in from the coast.

Close to the head of the Catalla slough, and on one of the seepages of oil, the Alaska Steam-Coal & Petroleum Syndicate, Ltd., has sunk a well 365 feet deep and has a flow of oil. The well was capped the second day after the oil was encountered, hence its capacity was not fully determined, but during the time it was flowing it shot up at intervals a jet of oil 60 feet above the top of the derrick through an 8-inch pipe, and since the well was capped there is a heavy leakage of oil and gas around the casing of the well. Following is the log of the well as driven:

	Feet.
Surface drift	5
Broken shale	10
Light colored shale	140
Fine grained sandstone	18
Seam of coal	½
Hard dark shales	190
Stratum of quartz	½
Oil-bearing sand	1
Total	365

A second well has been sunk 1700 feet by the Alaska Coal & Petroleum Co., but so far no oil has been obtained, though the well is going through the same formation as that in the English company's well. This well is situated about ½ mile southwest of the English company's well.

Several other wells are being prepared and inside of sixty days six new wells will be under way.

Practically all the oil-bearing lands that show any signs of being worth anything, and some that are worth nothing, have been located during the past eight months. As near as can be estimated nearly half a million acres of oil lands have been taken up.

The coal croppings, of which most is known, lying 20 miles northeast of Catalla, occur in the valleys of Sheppard, Trout, Clear, Carbon and Canyon creeks, and also on the hills between these streams. There are six veins of importance ranging from 4 to 30 feet thick. The coal in the veins is practically free from shale, though there are occasional bunches of iron sulphide. The veins dip 40° to 60° north. The coal is so situated that it can be mined by tunnels. The grade of the coal in the several veins varies, some of the larger veins carrying as low as 60% fixed carbon, being a fair grade of bituminous coal. One of the veins on Trout creek has been found by working test to make very good blacksmith coal. Most of the veins contain a semi-anthracite coal, which makes good steam fuel. Their general physical appearance is that of bituminous coal. The samples taken so far are from the surface.

Practically all the important available lands known to contain coal have been located and are being developed. The total area of coal land in the section north of Catalla and in the district to the east of the Behring glacier does not exceed 200 square miles. The district east of the Behring glacier has not been explored as fully as that north of Catalla, but the best part has been recently located, and it is stated the coal showings are larger than those in the western end of the field, the coal being of the same quality.

The following is an analysis of coal from the district:

	No. 1. 7-ft. vein.	No. 2. 12-ft. vein.	No. 3. 4-ft. vein.
Moisture	1.5%	1.5%	1.7%
Volatile matter	18.0%	10.5%	10.0%
Fixed carbon	75.0%	85.7%	84.2%
Ash	5.0%	1.8%	3.8%

The oil found throughout the district appears to be of the same character. It is stated by the chemists who have analyzed it to have a paraffine base. The following analysis was made in Seattle from a sample of the crude oil taken from the well at Catalla:

Naphtha	34.2%
Illuminating oil	34.4%
Lubricating oils	16.5%
Coke and residue	14.5%

Specific gravity, .800.

Another analysis made in Los Angeles, Cal., gave:

Specific gravity	.7957 (45.9° B.)
Cold test	Not chilled at 3° below zero
Naphtha	38.5%
Illuminating oil	31.0%
Lubricating oil	21.5%
Coke and loss	9.0%

Oil has a flash test of 70° to 80°.

Oil is light green in color.

In addition to the oil and coal lands a small area of placer gold has been discovered and worked in a small way for the past five years. The bluffs near Cape Yaktag carry small amounts of fine gold, which yield about $3 per man per day. On White river, in the same section, and 5 miles up from its mouth, a year ago a small area bearing coarse gold was discovered and is being worked. It is stated that only about 2 miles of the channel is profitable. The value has not been fully demonstrated as yet. The ground is from 3 to 6 feet deep to bedrock. The gold is coarse, varying from the size of a large pin head to that of a small bean, and is worth about $18.50 per ounce. The source of this gold is probably some deposit under the Malaspina glacier under which the White river rises. The district is not fully explored, but from information available it does not appear that there is a probability of much gold-bearing placer ground being found.

The Kayak district is reached by steamers running direct from Seattle, Wash. The trip occupies seven to nine days, depending on the state of the weather. For the Kayak-Catalla section and the Yaktag section the point of debarkation is Kayak village, on Little Kayak, or Wiggham island, where there is a small settlement, whence Catalla and other points on the mainland are reached by rowboats, launches, etc. To reach Yaktag it is necessary to walk along the beach from the Ochtilee spit, opposite Kayak, 60 miles, as there is no harbor or landing place that is safe and available during bad weather nearer to Yaktag than Kayak, though during fine weather small boats may be landed on the beach at Yaktag. To reach Orca section one can go on the steamers to Orca, where there is a safe harbor. No reliable charts or surveys of the coast from Yaktag to Orca have been made, hence the steamers on this run will not land freight directly on the mainland. All passengers and freight are landed at either Kayak or Orca, but mostly at the former place, thence being transferred on lighters and small boats to Catalla, Chilkat Point, or Ochtilee spit as required. The United States Government has ordered a survey of the shore line made, and will determine whether it will be possible to obtain a landing safe at all seasons at some point either in Controller bay, or near it on the mainland.

There are postoffices at Orca and Kayak and one is to be established at Catalla, which place is a more convenient point for most of those operating in the district. Hotel accommodations are limited at Kayak and Catalla, though there are stores carrying small stocks of staple goods.

There are a number of small boats running between Kayak and the mainland, and there is no difficulty in getting to and from the various points.

White labor, up to a few months ago, was scarce, there having been no demand for it until recently. The natives can be hired for "packing," boating and certain other classes of work, but are not skilled outside the above mentioned things, to which they are accustomed. They are quick to learn, are generally superior to most of the coast natives, but are few in number. They demand and receive the same pay as white men.

The run of the oil stream or pools will probably be difficult to determine at first, owing to the fact that a large portion of the uptilted part of the country, back in the coal range and in front of the main St. Elias range, is covered perpetually with a thick bed of snow and ice, making much of the information that would be of use in determining these matters unobtainable. From known facts, however, it is thought that the best and most permanent wells will be found on the east end of the Yaktag section, as this part of the belt is less broken than any of the rest of it.

Hints on Amalgamation.

Written for the MINING AND SCIENTIFIC PRESS by W. H. KRITZER.

As ore conditions vary in different localities, the directions following for the preparation and cleaning of plates apply only in a general way, for the practical millman will prefer to prepare the copper plates under his charge in a manner that has proven to give the best results in saving the values from the ore that is being crushed.

To keep mercury, it should be placed in a large jar or wide-mouthed bottle, and for every five pounds of mercury a solution of one pound of sal-ammoniac and two pounds of quicklime, with enough water to dissolve, should be added.

An occasional shaking will keep the mercury in this jar in proper condition for dressing plates.

To retort and clean foul mercury, fill the retort about one-half full and cover with a layer of powdered charcoal or quicklime. Lute and wedge the cover on the retort, and, if the pipe has no water casing surrounding it, cover it with wet cloths and keep wet, allowing the lower end to extend into the vessel of water placed below to catch the distilled mercury. Heat the retort gradually until nearly red. Remove the fire before it is fully red, and allow to cool, keeping the water running in the meantime.

To clean mercury without retorting, place the foul mercury in a jar or large bottle. To this add a mixture of one cupful of nitric acid and ten cupfuls of distilled water. Shake occasionally and allow it to stand for twenty-four hours.

DRESSING THE PLATES.—Rinse off thoroughly with clean water, using a hose, and, if dark or fouled, go over them with a brush or flannel mop, using a weak solution of sulphuric acid or cyanide of potassium, which may be strengthened up to as much as one part of acid to ten of water, if required.

For general purposes use: Caustic soda, 5 ounces; cyanide of potassium, 2 ounces; dissolved in five gallons of water.

When blackened or fouled with black sulphurets use: Carbonate of soda, 8 ounces; sal-ammoniac, 16 ounces; lime, 48 ounces; or to five gallons of salt brine add one-half pint of sulphuric acid.

When blackened or fouled with oxide of manganese, sulphate of copper or zinc, take: Muriatic acid, 1 pound; distilled water, 5 gallons.

After having cleaned the plates and used one of the above solutions, take from the jar a small quantity of mercury and place it in a small bottle. Then stretch a piece of muslin over the mouth of the bottle and sprinkle the plate with the mercury; rub it smooth with a flannel mop in clean water. In starting new plates do not clean up too often; allow the amalgam to pile up, applying the quicksilver until it is well built up; but do not allow the amalgam to

harden and scale on the plates, as it should he kept just soft enough so it will not run, and when ruhhed up with the finger have a similar feeling to putty. As the amalgam accumulates, do not allow it to collect in bunches, hut take a brush and go over the plates from side to side; the fine ridges formed will be an aid in the collecting of the gold.

To remove amalgam, use a thick piece of ruhher or leather. Do not use a metal scraper. Do not clean too close, as the gold will not he lost, or the silver either, and you avoid the danger of scraping off the silverplating and giving verdigris an opportunity to form on the copper, which is so detrimental to the plates. If the amalgam is hard and does not remove easily, dip the plate in warm water.

Better results have been attained hy having plates with a wide surface and a very slight fall; for with a narrow surface and a heavy fall, the fine or float gold (in a thick hody of water) can not come in contact with the surface and is carried off.

Notes on the Metallurgy of Copper of Montana.*

Written by H. O. HOFMAN.

In 1901 the United States produced 268,782 long tons of fine copper. Of this total, Montana is credited with 102,621 long tons, or 38.2%.

The leading smelting works are located in Butte, Anaconda and Great Falls. In Butte are the works of the Colorado Smelting & Mining Co., the Colusa smelter of the Montana Copper Co. (closed in 1888), the plant of the Parrot Silver & Copper Co. (closed in 1899), the Bell plant (closed in 1884), the Clark's Colusa (closed in 1888, then come the active works of the Colusa Parrot Mining & Smelting Co. (Butte Reduction Works), the Butte & Boston Consolidated Mining Co., and the Montana Ore Purchasing Co.

In Anaconda are the old and new (Washoe) works of the Anaconda Copper Mining Co.; in Great Falls the establishment of the Boston & Montana Consolidated Copper & Silver Mining Co.

The active works furnished in 1901, approximately, the following amounts:

	Pounds.
Anaconda Copper Mining Co.	113,800,000
Boston & Montana C. C. & S. M. Co.	54,700,000
Montana Ore Purchasing Co.	29,900,000
Butte & Boston Con. M. Co.	22,200,000
Butte Reduction Works	18,000,000
Colorado Smelting & M. Co.	7,500,000
	246,100,000

The discrepancy of 17,000,000 pounds of copper hetween the figures of production is due to the fact that the matte of some works is converted in others, and that both are credited with the copper they turned out.

PAST AND PRESENT PLANTS.—The Colorado Smelting & Mining Co. was started 1879 hy the late Henry Williams. The ore was roasted at first in the long-hearth hand reverberatory furnace, having a hearth 12 by 50 feet, and then smelted in a reverheratory matting furnace with hearth 14 feet 7 inches hy 9 feet, wood heing used as fuel. The original smelting furnaces treated twelve tons of ore in twenty-four hours, producing matte assaying 60% copper and 700 to 800 ounces silver to the ton, which had to he hauled 200 miles to reach the railroad. In 1889 Bruckner cylinders came into use for roasting ores; followed in 1892 hy the R. Pearce single-deck turret furnace. In 1894 Pearce's first douhle-deck turret furnace was added, and in 1901 the first six-deck turret furnace of R. F. Pearce was put in operation. At present (summer, 1902), the roasting department has four single-deck turret furnaces with 6-foot hearths, five douhle-deck turret furnaces (one with a 6-foot and four with a 7-foot hearth), and one six-deck turret furnace with a 7-foot hearth.

The hearths of the reverheratory matting furnace were made 21 hy 12 feet in 1889, increasing the ahove capacity to eighteen tons in twenty-four hours. At present there are three matting reverberatories with hearths 47 hy 20 feet (the first of these larger furnaces having heen erected in 1899). The matte, containing copper 50% to 55%, silver 100 ounces, and gold 1.5 ounces to the ton, is sold.

The Colusa smelter of the Montana Copper Co. started 1880 by A. Wartenweiler, with four long hand reverheratories for roasting (hearths 60 feet hy 11 feet 6 inches) and two reverheratory matting furnaces (hearths 15 feet 9 inches by 10 feet). Smelting begun in 1881; a reverheratory matting furnace treated in twenty-four hours twelve tons of raw and roasted ores, producing 65% copper matte, with a consumption of ten cords of wood. Lump ore was at first heap-roasted, hut, stopped on account of the smoke nuisance, was replaced in 1882 hy stalls. In 1884 there was in operation, hesides the stalls, twelve long-hearth hand reverheratory roasting, six reverheratory matting and one hlast furnace. The latter, 3 feet hy 4 feet 6 inches at the tuyeres and 10 feet high, was run with charcoal. Works sold 1888 to the Boston & Montana Con. Copper & Silver M. Co., and formed the so-called Upper Works. Closed down 1893, when the new Great Falls establishment of the company made them superfluous.

The Parrot Silver & Copper Co., started July, 1881. Ore at first roasted in eleven long hand reverheratories (hearths 60 hy 14 feet) and smelted in six matting reverheratories (hearths 14 feet by 11 feet 6 inches). Weight of smelting charge, two to three tons; ten tons put through a furnace in twenty-four hours. Matte (60% to 67% copper and forty to forty-five ounces silver per ton) at first hrought forward to hlister copper, hut this soon given up on account of the excessive cost, and the fact that matte was more easily marketed than blister copper. Shortly after starting of works, a stall 40 feet long and 9 feet high was hult hy J. T. Reese to roast lump ore. It proved a failure and was replaced by A. J. Schumacher with open stalls, 8 feet deep, 6 feet high and 6 feet wide. In 1891 there were in operation 120 stalls. The hand reverheratory roasting furnaces were supplemented, 1889, hy two small Spence mechanical shelf-roasting furnaces, each treating five tons of concentrates in twenty-four hours, reducing the sulphur to 6% to 7%; these replaced 1892 hy a round, and 1893 by two ohlong Keller-Gaylor-Cole mechanical shelf-hurners.

A Roherts four-hearth mechanical reverheratory roaster, similar to the Wethey furnace, was put in operation 1897. Hearths of matting reverheratories enlarged in 1887 to 16 feet by 12 feet 6 inches. For lack of space they never reached the large sizes of the other furnaces at Butte. The largest furnaces, 1895, had a hearth of 22 feet hy 16 feet. In 1884 a Herreshoff 48-inch water-jacket hlast furnace was erected hy E. D. Peters; in 1885 a 3-foot by 6-foot hlast furnace, with cast-iron water jackets, was added, hut was soon replaced hy A. J. Schumacher with a 3-foot hy 8-foot furnace having steel jackets. In 1884 the converting of copper matte was hegun under the general direction of the inventor of the process, P. Manhes. The practice was to melt 40% to 50% copper matte in a cupola furnace, tap it into converter, blow to white metal and pour, then melt the white metal in cupola and hlow it to blister copper in the converter. In 1885 A. J. Schumacher succeeded in making metallic copper from 40% to 50% matte in one operation of two consecutive stages, and thus laid the foundation of the modern practice of converting.

When the works were closed down, August 20, 1899, the roasting department contained two Keller-Cole-Gaylord furnaces, each having a capacity of fifty tons ore, and one O'Hara furnace, treating fifty tons in twenty-four hours. Smelting was carried on in three under-grate hlast reverheratory furnaces with hearths 20 hy 12 feet, treating altogether 135 tons of ore in twenty-four hours, and in two hlast furnaces, 44 inches by 96 inches at the tuyeres, each putting through daily a 120-ton charge. The converting department had six upright converters, 5 feet in diameter and 8 feet 6 inches in total height.

The Bell plant was huilt soon after the erection of the Parrot works, which roasted in long-hearth reverheratories and smelted in blast furnaces. In 1885 it had two hand roasters and two hlast furnaces.

Clark's Colusa was built 1884 by W. A. Clark; sold 1888 to Boston & Montana Co., and formed its lower works; closed 1893 in favor of the new plant at Great Falls. At this plant the first two-hearth, mechanical O'Hara roasting furnace was operated, 1885; the hearths were 50 hy 7 feet. A second O'Hara furnace, erected 1885, had hearths 70 hy 7 feet, and treated thirty tons ore in twenty-four hours. In 1891 ores were roasted in three O'Hara furnaces and one 10-ton Bruckner cylinder. The first smelting furnace, a circular, water-jacket hlast furnace, 36 inches in diameter at the tuyeres and 9 feet high, was replaced 1885 by a larger furnace. In 1887, two 50-ton circular, water-jacket hlast furnaces were put in operation. In 1886, two reverheratory matting furnaces were added to the plant, each treating a twelve-ton charge in twenty-four hours.

The Colusa-Parrot Mining & Smelting Co.'s plant, Butte Reduction Works, started 1885 hy employes of the Parrot smelter. At first ore was roasted in heaps and then smelted (forty-five tons in twenty-four hours) in a 36-inch water-jacket hlast furnace. A long hand reverheratory (hearth 100 by 14 feet), erected 1886, remained in operation until 1888, when it was cut in two, making two furnaces. In the same year the first Bruckner furnace was installed (cylinder 15 hy 7 feet; charge, seven tons). In the fall of 1889, a second cylinder, 20 hy 8 feet. In 1894 the first four-deck Wethey calciner was huilt, replacing one of the 50 by 14-foot hand reverheratory roasters and the 15 by 7-foot Bruckner cylinder. Its work proving satisfactory, a second Wethey furnace was erected. The 50 by 14-foot hand roaster was replaced hy a larger furnace, 75 by 5 feet, to he used mainly for roasting slimes. In 1898 the third, and in 1900 the fourth Wethey furnace was installed, replacing the remaining hand roasters and Bruckner cylinder. Smelting capacity of the plant increased, 1886, hy erection of a 96 hy 42-inch Orford hrick furnace. The original 36-inch furnace was put out of blast and replaced in 1889 hy a furnace 38 inches diameter at tuyeres. In 1897 a sectional hlast furnace of the United Verde hot air type, 84 hy 42 inches at tuyeres, replaced the two older furnaces. In 1900 a second rectangular furnace, 112 hy 42 inches at tuyeres, was put in blast, and in 1901 the 84 hy 42-inch furnace was enlarged to 112 by 42 inches.

First reverheratory matting furnace (hearth 15 hy 9 feet) erected 1887; the second (hearth 18 hy 11 feet), treating from twelve to fifteen tons per twenty-four hours, erected 1888. Then customary to wet down the roasted ore and shovel into the matting furnace through the side doors. In 1889 hoppers placed over the furnaces and roasted ore charged hot through the roof. This increased smelting capacity from eighteen to twenty-one tons in twenty-four hours. In 1896 one large reverberatory matting furnace (hearth 35 hy 16 feet, capacity forty-five to fifty tons ore in twenty-four hours) replaced the two smaller furnaces. A second (hearth 45 hy 16 feet, capacity fifty-five to seventy tons) was huilt in 1897; and in 1900 a third (hearth 50 hy 20 feet, capacity 85 to 100 tons). This last did so well that the 1896 furnace was rebuilt on the lines of the furnace of 1900. Present plant: Four Wethey four-deck calciners, two water-jacketed hlast furnaces (112 hy 42 inches at tuyeres) and three reverheratory matting furnaces (hearths 45 by 16, 50 hy 20, and 50 hy 20 feet).

The Butte & Boston Con. M. Co. works started 1885 with four Bruckner cylinders (8 by 18 feet), two reverheratory matting furnaces (hearths 22 by 17 feet, treating five-ton charges), and two hlast furnaces, the larger heing 96 hy 36 inches at the tuyeres and 11 feet high. In 1889 two O'Hara roasting furnaces were added; later four Allen-Brown-O'Hara furnaces; and, these giving satisfaction, the original O'Hara's were remodeled to the Allen-Brown-O'Hara type, and the Bruckner cylinders thrown out. In 1892, when the plant hurned, eight Allen-Brown-O'Hara furnaces were in operation. The plant was rehuilt, the Allen-Brown-O'Hara furnaces repaired, hut not the Bruckner. A new blast furnace, 96 hy 36 inches and 16 feet high, was erected to take the place of the old small cupola. The furnace was originally provided with a hell and hopper feed, which proved too expensive. In 1901 the width of the new furnace was increased to 40 inches and the height reduced to 11 feet. Up to 1893 the hlast furnaces smelted little but roasted concentrates. Matting reverberatory furnaces remodeled and increased in size 1895. Converter plant started 1900. Present plant: Eight Allen-Brown-O'Hara roasting furnaces (hearths 90 hy 9 feet), four matting reverheratories (hearths 50 by 20 feet, the first furnaces of this size having heen huilt in 1899–90), one hlast furnace 96 hy 44 inches at tuyeres and 9 feet high, and three horizontal converters with harrels 10 feet 6 inches by 7 feet.

(TO BE CONTINUED.)

*Trans. Am. Inst. Min. Engs. (Condensed).

Archæan and Algonkian.

The Archæan is the oldest known geological formation. It is characterized hy the entire ahsence of clastic rocks, such as quartzite and sandstone, and consists wholly of granitic, schistose and gneissoid rocks, and is essentially the same wherever found. One of these kinds of rock may occupy large areas, hut when a variety of rocks occur in a single area their geological relations are usually very complex. They are completely metamorphosed, the mineral constituents much contorted and hroken, indicating that the rocks of the Archæan have been suhjected to repeated metamorphosis and powerful dynamic movements. The actual derivation of the Archæan is still somewhat douhtful. They may he metamorphosed sediments, which would require the conception of still older rocks, the degradation of which has furnished the material for the later sediments. It is thought hy some authorities that these rocks represent igneous masses intruded into older sediments, the whole of which, both sedimentaries and intrusive masses have heen extensively metamorphosed, or they may he considered as wholly igneous and representing either a portion of the original crust of the earth, or else originally crystallized material which now reached the surface in consequence of inward crystallization and suhsequent erosion. The Archæan rocks are unlimited in downward extent, hut are limited ahove by the Algonkian. The determination of Archæan areas is usually made on lithologioal grounds. In different parts of North America are one or more series of clastic, that is, fragmental rocks, between the Archæan and the hase of the Camhrian. Noted regions in which these rocks occur are in Canada, in the Lake Superior region, in Newfoundland, New Brunswick, the Black Hills of South Dakota, in Missouri, in Texas, in the Rocky mountains, in Arizona, in California, in the Grand Canyon of the Colorado river, in British Columhia, in the Adirondacks, and elsewhere. These rocks are all classed as Algonkian. In some regions it is comparatively easy to recognize the Algonkian, particularly where there is non-conformahility of strata, hut as often it is difficult to thus differentiate the Algonkian from the Archæan on one side and the lower Cambrian on the other. The Archæan, Algonkian and Cambrian formations are noted carriers of ores, in which gold, silver and copper and iron deposits are the most extensive and valuahle.

Mining in Broken Hill, New South Wales.*

NUMBER III —CONCLUDED.

Written by EDWIN K. BEAUMONT.

Another modification of the square set system as adopted in the Central mine is known as the "block system" (see Figs. 10 and 11). The lode for its entire length through M. L. No. 9 has been surveyed into parallel blocks each 50 feet wide—i. e., ten sets, each 5 feet wide. Each alternate division is a block and the next a stope. The whole level is gradually developed by a drive along the foot wall and by crosscuts to the hanging wall, thereby determining the width of the lode along its entire length, and the stopes are then carried from the foot wall to the hanging wall on the sill floor, and the space filled with square sets, leaving every facility for forming the necessary gangways, chutes, etc. These are then filled in with mullock and the stope starts on its course upwards, being exactly 50 feet wide the entire width of the lode at that point, thus leaving a pillar of ore 50 feet wide on each side of it from wall to wall, which will carry all pressure during the mining of this stope. A run of square sets is put in each side of the stope as it goes upwards, forming a gangway and ladderway, the sides of which are lathed or paddocked off, thereby confining the mullock filling in the center of the stope. The ore is broken by machine drills driven by compressed air, and in the same lifts and proportions as in the before mentioned open stope system. The ore falling on the mullock filling in the center of the stope is popped and spawled into suitable size for handling and trucking to the shaft for haulage to the surface. One great difference in this system from the others is that the winzes—6x5 feet—are always sunk 100 feet apart at the side of each alternate stope, being half in the stope and half in the adjoining block, thereby saving a second winze when the block is being taken out at any future time. The ore from the adjoining stopes having been all extracted, and the space filled with the mullock, this winze will then be available and serve the same purpose for the remaining block. The same advantages of ventilation, mullocking and stoping all apply to these stopes, as in the foregoing open cut and sloping stope systems, and they are mullocked up in the same manner, excepting that the chutes for conveying the ore from the working faces to the sill floor are placed in the runs of sets, placed on the sides of the stopes for that purpose, and the chutes can be placed at any suitable intervals for the workings.

The advantages and disadvantages of these several systems are: The whole of the ore body is, or at least eventually can be, extracted, and after extraction of lode material comparatively few, if any, large voids or openings are left, which also leaves the surface areas for works, mills, machinery, etc., almost free from risk of subsidence. The great advantage evident from the presence of mullock filling—in lieu of a forest of timber—is the immunity from risk of fire. The miner is always in reach of the "back," i. e., from 3 feet to 9 feet, and can readily sound and examine the back of the workings, and thereby make sure they are safe; this ensures a great freedom from accident caused by masses of ore falling on men while at work immediately under them, though, unfortunately, recent experiences have shown that, as far as human knowledge or judgment can avail, a place may be sounded and examined by miners with a lifetime experience and reported as safe, when a few hours afterwards the back falls in and reveals a fault or crack which the sounding did not make known, serious or fatal accidents consequently resulting; but even then this cannot in any way be compared to the great risk incurred by men when re-erecting square sets that have been knocked down by a heavy shot, when sometimes a charge will bring away more ground than anticipated, for then a dozen or more sets will come down, and the men will have to work under, probably, a dangerous back in re-erecting the sets or staging before they can actually examine it and assure themselves of its safety. Another advantage is the saving in the expense of timber. Of course, against this must be placed the cost of quarrying the mullock filling on the surface and conveying it to the stopes, which would, however, be required in any case in filling the square sets in the other systems. The great advantage of good air is important, as the mullock fills in all spaces except the winzes and stope itself where it is being worked, thus ensuring always at the working face a current of air, which also carries off the smoke after firing and adds to the miners' health and comfort, removing much that in former days made the miner's life a hazardous and unhealthy one.

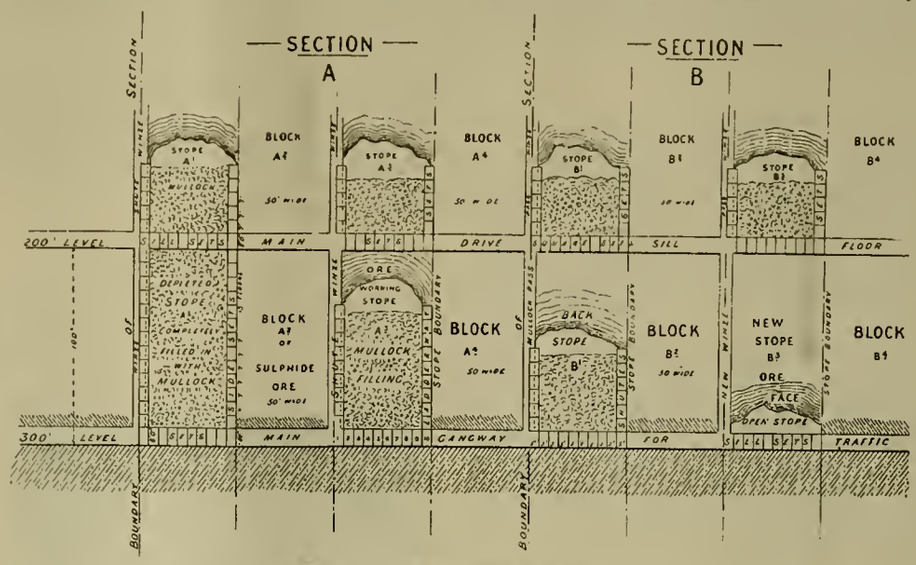

Fig. 10.—The Block System of Stoping.

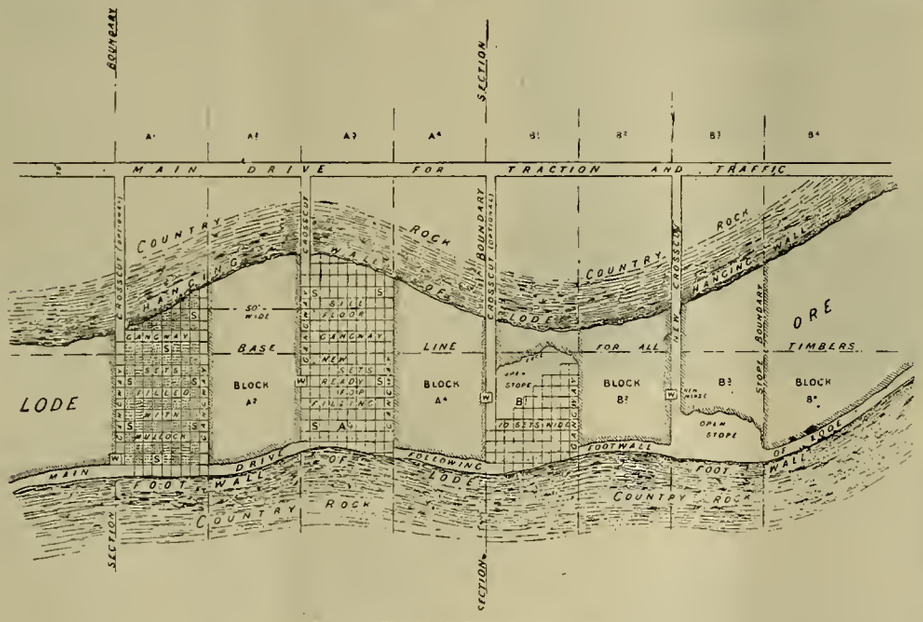

Fig. 11.—The Block System of Stoping.

CONCLUSION OF UNDERGROUND STOPING.—There is one other important method employed, and by which a large amount of oxidized ore has been removed. I refer to the open-cut system and surface extraction. In reference to the open-cut system I am indebted to J. J. Shaw, engineer in charge and manager for Baxter & Saddler's contracts in working their open excavations, for his courtesy in supplying me with the necessary data, drawings, etc.

OPEN EXCAVATIONS.—The large surface excavations are one of the chief sights of Broken Hill, and though descriptions may give a slight idea of their extent, I think they must be seen to be understood or appreciated. Imagine an open cavern, three-quarters of a mile long, traversing the whole of the Broken Hill Proprietary Co.'s blocks 11, 12 and 13, each of which is 20 chains along the line of lode and 20 chains wide. The widths of these cuttings vary from 120 feet in block 11 (in what is known as Smith's cut) to about 350 feet wide across Baxter & Saddler's cutting in block 12. There is also a great width of 300 feet opposite McGregor's shaft in the center of Block 11. The cuts are down about 250 feet, and they are recovering a large amount of timber that was used underground in the square set system of stoping in the old 200 level workings, the ore from which was then hauled up the various shafts before the open cuts reached their present depths. The great mass of over-burden, mullock, country rock, etc., that has been removed in the extraction of the ore, can be imagined by the

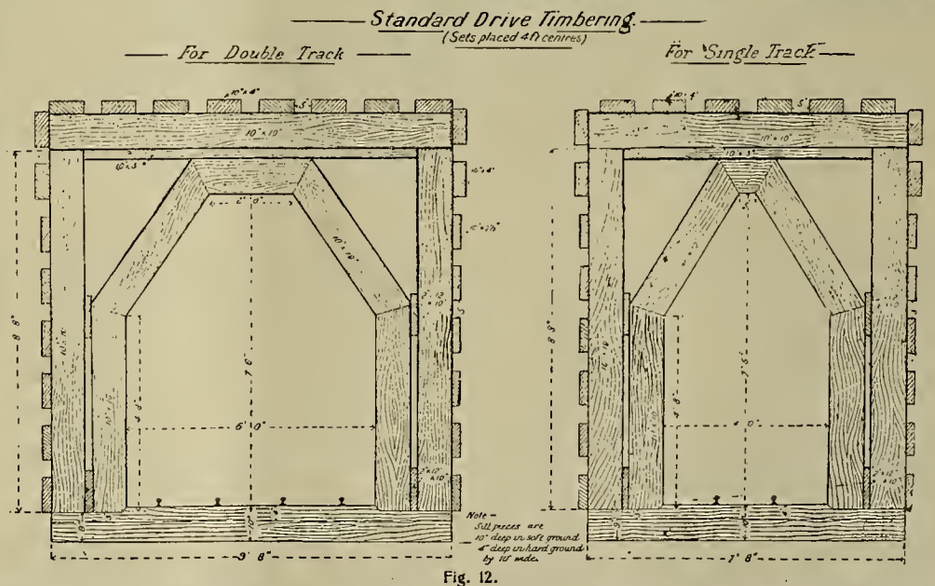

Fig. 12.

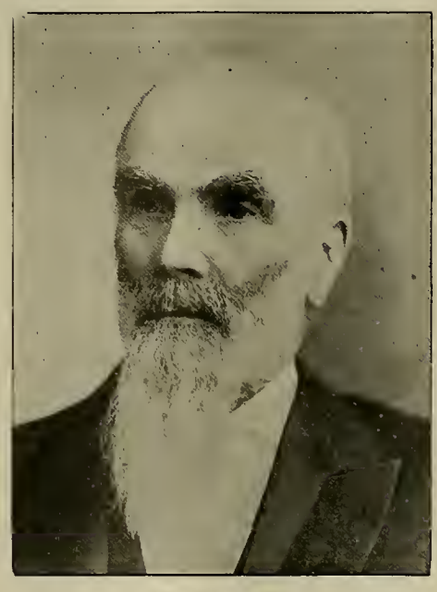
heaps on hoth sides of the line of lode, reaching (near the outer portions) a height of 60 feet or more (the angles of repose heing hetween 30° and 40°). The areas covered hy the hase of these heaps (following the area described hy the toe of the various dumps) will almost equal the area of the adjoining hases of the lode; in fact, supplementary leases have heen taken up on which the mullock heaps and dehris have heen deposited.

INCLINE TRAMWAYS.—One of the most interesting features of the works is the system of "incline tramways," hy which the waste is removed from the cuts. The grade is 2 feet to 1 foot approximately; they are always douhle lines, and two end-tipping trucks, called "dohhins," are used, heing hauled hy a ¾-inch wire rope attached to a hauling engine or winch having a loose drum and 9-inch cylinders, approximately 15 H. P. The empty dohhin runs down the incline, while the full one is heing drawn up, thus aiding the traction of the loaded one. On arrival at the surface, near the engine room, the full dohhin is stopped hy placing a "sprag" on the wheel (this is a piece of hardwood about 18 inches or 2 feet long and 4 inches in diameter); the hauling rope is detached, and a horse hitched to the dohhin, which is then drawn along a surface line of 3 feet 6 inches gauge, and heing an end-tipping truck is run to the end of the hank, where a "cradle" or tipping trough of old sleepers is formed; the sudden impact of the front wheels in this cradle causes the dohhin to discharge its load over the end of the dump; of course, as the dump grows the cradle or tipping trough is removed to the outer edge, the invert heing generally about 6 inches helow the level of the line.

HORSES.—Horses are used in running out these dohhins. The driver runs alongside and on nearing the end of the dump pulls a strap fastened near the hreeching, which releases the fastening attaching the horse to the dohhin. The horse immediately runs off the line and allows the dohhin to pass him, and then trots up hehind and turns round, ready to he re-hitched to the empty dohhin to draw it hack to the cutting again, often needing nothing more than a word from the driver. Unfortunately the animals working in the hottom of the cuts, where the oxidized ore is mined and dust frequently blows ahout, sometimes get leaded, and then become the same type of wreck that the men do when they suffer from the same malady, which, since the stopping of the smelters on the Barrier, I am pleased to say, is not such a menace, or nearly so prevalent as in the early days. This, I think, is largely due to the greater cleanliness of the workmen and the increased facilities given hy all the mining companies—for each mine has its own changing house, where the men can indulge in a hot or cold plunge or shower hath. Yet it is remarkahle how many miners go home daily covered with black sulphide dust, looking more like ahorigines than white men.

FLYING FOX.—The next most important method of extraction and that hy which the greater part of the ore from the open cuts is raised to the surface is the "flying fox," which is the name given to a large skip which is hauled up and conveyed along an aerial ropeway, and thence discharged into large ore bins at the sides of the railway lines on the surface, from which it is conveyed to the mill or to the smelters. A mast is erected on each side of the cut and a cahle stretched over an iron saddle near the top. The cable is anchored securely on either side, while on the surface is located the hauling engines, of the same type as used on the incline, having a loose pulley and reversing gear. An attachment called a bicycle runs along the main cable across the cut, having on it four pulleys. The upper two travel along the cable, the lower two heing used in hoisting the skip vertically from the cut, and the same rope—called the "traveling rope"—then draws the hicycle, and, of course, with it the skip along the cable. When it is over the bin on the surface a self-acting catch holds it steady, while it is lowered and discharges its load into the hin. The skip is again hoisted and is run out along the cahle and again lowered into the cutting. In the meantime a second skip has been filled and it is attached and hoisted and discharged as before.

The skips are ahout 1 foot 4 inches deep, 4 feet wide and 5 feet long, and hold about 1 cuhic yard. They are suspended hy four chains, one at each corner, the hack two heing fixed to the skip, while the front ones are fastened hy hooks, which are undone to release the load. These skips are used for many purposes besides hauling ore, for I have seen a workman with a hroken leg hauled to the surface and deposited safely, thus saving a steep climh up the hanks. The sides of the cutting are designed with a slope of a half to one and three-quarters to one, and would meet at a depth of ahout 250 feet, but owing to the frequent slips of the sides they are at present very irregular. Some very heavy firing is done in these cuttings, which shakes the ground for a great distance, hut great masses of the rock are removed.



ORE BODY.—The ore hody in the center of the cut is ahout 25 feet to 50 feet in width. The open cutting in Baxter & Saddler's contract, block 12, and also in Smith's cutting, hlock 11, are now working immediately ahove the fire area, and frequently pieces of hurnt timher and slagged rock are found. These cuts were of great use in coping with fires underground hy pouring large quantities of water down the shafts right ahove the fire area.

DRIVE SETS.—There is one other feature to which I will draw your attention, viz., the sets as used in the douhle track drives, where horses are used underground. The application of these will he evident from the drawing (Fig. 12). They are specially designed to withstand heavy vertical and lateral pressure, and are placed at intervals according to the nature of the hack or country they have to hold, hut generally ahout 4 feet to 5 feet center to center.

It may he of interest to know that the horses used in underground traction are stahled underground and seem to thrive well, for they are all in good condition and take kindly to their work. The stahles are lighted with electric light.

Passing of a Noted Man.

In last week's issue appeared a hrief notice of the death of Thos. Chalmers in Chicago, Ill., on July 13th. The man whose portrait appears herewith retired from active husiness in 1893. He was one of the founders of the firm of Fraser & Chalmers, who com-

Thos. Stuart Chalmers.

menced husiness in 1872 in Chicago, succeeding the Eagle Works Manufacturing Co., after P. W. Gates, president of that company, had decided to liquidate after the great fire of 1871. Fraser & Chalmers commenced operations with sixty men on property 60x145 feet, and two years ago when they were ahsorbed hy the Allis-Chalmers Co. they were working 1500 men in Chicago and 1000 men at shops they had huilt in England, at Frith, Kent.

Thomas Chalmers was a skilled mechanic of the old school, who, having served an apprenticeship of seven years in Scotland, received the balance of his education, both technical and commercial, hy contact with the world and learning its requirements. His life is a history, when one considers that he came to Chicago when it had a population of 4000 people; that he lived there sixty years; that he was in touch with the development of the Middle West and the great North-west, and had to do personally with so many large institutions where power or machinery has been required from the heginning to the present day in the development of this great country.

Thomas Stuart Chalmers was horn June 14, 1816, at Dronley, near Dundee, Scotland. His father, William Chalmers, was a manufacturer of linen. At that time it was all done hy hand weaving. People in those days never went 20 miles away from where they were horn. There were no railroads or conveyances of any kind in Scotland—none there or here either—no steam loom weaving—everything done by hand weaving. William Chalmers, father of Thomas, did it all in his place. People for 20 or 30 miles around delivered the webs to him at Dronley. He went to school until he was 14 years of age, then went to learn his trade—that of a machinist—at Brown & Allen, Dundee, manufacturers of spinning machinery. At that time steam-spinning machinery was heginning to be manufactured.

Mr. Chalmers served seven years as an apprentice and was paid half a crown (equal to 56 cents American coin) a week from the heginning, and was raised a shilling per week every year, making 2s 6d for the first year; 3s 6d for the second; 4s 6d for the third; 5s 6d for the fourth; 6s 6d for the fifth; 7s 6d for the sixth; 8s 6d for the seventh—equal to ahout $2.12 per week at the end of the seven years—which was considered fair pay. At the end of the seven years Chalmers went off as a journeyman machinist to a place called Fyfe in Fyfeshire, Scotland, ahout 15 or 20 miles from Dundee. There were no railroads, so he had to walk it and alone. He worked in that shop for three years (Brown & Co.) as an erecting machinist, putting up power spinning and carding machines in the different mills throughout Scotland, reaching these various mills hy stage. They were within a radius of prohably 20 to 25 miles. He got 18s per week at first and was afterwards raised to 20s—£1 a week—or ahout $5 per week. He had to pay 5s per week for hoard and lodging. There was no way really to spend the money outside, so the halance was practically saved. There was very little dissipation in those days. There were no visiting showmen nor circus nor traveling theatricals, hut lots of gypsys around the country who simply told fortunes. Tinkers made tinware and made horn spoons out of cattle's horns.

Once every year there was a country fair and cattle show and people came from the country all around. There were no prizes given nor offered. That was the time that people were engaged for the year, and that time they made engagements for lahor. The engagement was that they could neither discharge a man nor could he leave. If a man wanted to leave at the end of the year he could go to this fair and get another agreement for another year somewhere else and the hond was good. He could not he discharged nor could he leave, and if he did leave nobody would employ him; if a man tried to discharge him he could not do it unless he had good cause for it.

He went to Chicago in 1843 and went to work at the corner of Randolph St. and Fifth Ave., working there six weeks at $6 per week for a man named Nickerson. He had a small machine shop, all horse power machinery. He was to get $1 a day, hut never received anything, the time he worked there heing lost. Nickerson could not get any money for what he had done. He could not collect it. Chalmers did all kinds of repairing work there and put heating apparatus in the old Dearhorn school, on Madison St., hetween State and Dearhorn. He then went back to Lockport, Ill., and worked on his farm until the fall. He then went to Chicago again in the fall of 1844, walking hack and forth each time. He tried to get on hoard one of the steamers running from Buffalo to Chicago, daily line. He wanted to see if he could not work his passage down to Buffalo where he could get work at his trade, hut could not do it. When he came hack to Chicago in the fall he came alone and walked. He then went to work for P. W. Gates, who had a hlacksmith shop located then on what is the viaduct at Randolph St., hut was then West Water St. He was a young man and a hlacksmith and was working with his father-in-law, Hiram Scoville. They were hoth hlacksmiths, Chalmers heing the only machinist there. They were the only three in the shop, doing farm repair work and making wagons, plows and everything that came along. Chalmers was associated with Gates a great many years—until 1871; then, hecoming dissatisfied, he took a place as chief engineer on the Lady of the Lake. He stayed on the hoat a whole season up till Septemher, which was run hetween Chicago and Buffalo. It took twelve days to make the round trip—six days each way. She carried passengers. He received $40 per month and hoard. That was the first money he had seen.

The hriefest sketch of Mr. Chalmers' career would he a history of the industrial life of Chicago, in which for nearly sixty years he hore so honorahle a part.

United States Geological Survey in the Oil Fields of California.

The United States Geological Survey, within the last eighteen months, has heen making a preliminary examination of the productive oil fields of California, with a view, first, to acquiring a knowledge of the general conditions of occurrence of petroleum in the State, and, second, to applying the laws that may be deduced from such researches to other portions of the Coast Range. The director of the Survey has long recognized the paucity of knowledge relating to Coast Range geology, and in view of the fact that several of the formations of this region are oil-bearing he is now directing especial efforts to unraveling the intricate problems with which mining engineers, oil men and others have to do in the prosecution of their professional and industrial work. A considerahle numher of topographic maps, covering the agricultural regions of southern California, have already heen published—these with special reference to the water supply. Latterly other sheets of a similar nature, but covering more particularly the oil fields, hoth productive and prospective, have heen prepared and are now in the hands of the engraver. Still others are under survey in the field. Eventually it is proposed to cover the entire area of the Coast Range, the field work to he carried on as rapidly as the resources of the Survey will permit. The Survey has in press, for immediate publication as Bulletin No. 215, a catalogue and index supplemental to the catalogue and index published in 1901. The present catalogue hegins where the former ends; but there will he found in this index some entries—additional and corrective—which refer to papers covered hy Bulletin No. 177. The two bulletins constitute a general catalogue and index of the publications of the Geological Survey from its organization in 1879 to the present time.

Modern Practice in Hydro-Electric Plants.

Written for the MINING AND SCIENTIFIC PRESS.

One of the most important installations on the Pacific coast, when completed, will be that of the Columbia Improvement Co. of Tacoma, Wash., now under course of construction. The operative point of this installation is located on the Puyallup river, midway between Tacoma and Seattle. The initial water supply comes from the glaciers and snow peaks of Mount Ranier, forming the Puyallup river. The water is led from the river by a flume, and, taking advantage of a bend in the river, is carried 10 miles across country to a bluff, from which point it discharges into the river again, after passing through the wheels. The head available is 850 feet, and the water discharges onto the wheels through four separate pipes, each 48 inches diameter by 1650 feet in length, varying in thickness, according to the pressure, from ¼ inch at the top to ¾ inch at the bottom of the line. There are four main electrical units, consisting of 3500 K. W., 225 R. P. M. General Electric generators. Each generator is driven by Pelton wheels, direct connected. There are two wheels to each unit, the generator shaft being extended on either side and the wheels mounted on the overhang. The wheels proper consist of cast steel annealed centers, to which are bolted cast steel buckets, making the total wheel diameter 10 feet. The buckets are designed to take a 7-inch stream, and are 24 inches across the face, each bucket weighing 250 pounds. The total weight of each complete wheel and center is approximately 13,000 pounds.

Owing to the high head and extraordinary amount of power involved (each unit with its overload capacity is capable of developing 7500 H. P.), the finest mechanical construction is necessary. The interior surface of each bucket is carefully ground out to true hydraulic curves by means of special apparatus, and the buckets are independently weighed and balanced, there being less than ¼ pound difference in weight in any of them. The center is machined all over, and, when the buckets are secured, the complete wheel is adjusted to a perfect running balance of 225 R. P. M. The shaft, which carries the rotor and the two wheels, is of nickel steel, being 20 inches in diameter where rotor is carried, 16 inches at bearings and 14 inches where wheels overhang.

The bearings, two in number for each unit, are of exceptionally heavy construction; they are of the ring-oiling generator type, mounted on cast iron floor frames for setting in masonry foundation. Although of liberal proportions, the bearings are called upon to sustain an enormous pressure under high journal speed, and they are designed with every known safeguard.

In addition to the oil rings of usual type, the bearings are water jacketed with an auxiliary water pump and have independent oil pumps to insure oil under pressure being supplied to the journals at all times. As an additional precaution against overheating, each bearing is equipped with an electric thermostat and alarm, which indicates any rise in temperature above a certain point.

Water is supplied to each wheel through a combination pin and deflecting nozzle, enabling the most economic use of water at all stages of load.

The nozzles are controlled by special-type Lombard governors, designed for this particular work.

The main gate valve of each wheel is of the Pelton single-disc type, with outside yoke and screw and rising spindle, the body being of cast steel, annealed and bronze mounted. The valve stem is of nickel steel, and there are oil-packed steel roller bearings to take the thrust in all directions. This arrangement makes the gates readily operative, even under the extreme pressure. The wheels are inclosed in heavy, sheet steel housings, ribbed and reinforced to prevent vibration and noise.

In addition to the four main units, there are two exciter units of 200 H. P. capacity each, of the same general type as the main units. Thus, the total capacity of this plant will be in excess of 30,000 electrical horse power, which it is proposed to transmit to Seattle and Tacoma, each distant about 35 miles, for use in the various industrial enterprises thereabouts.

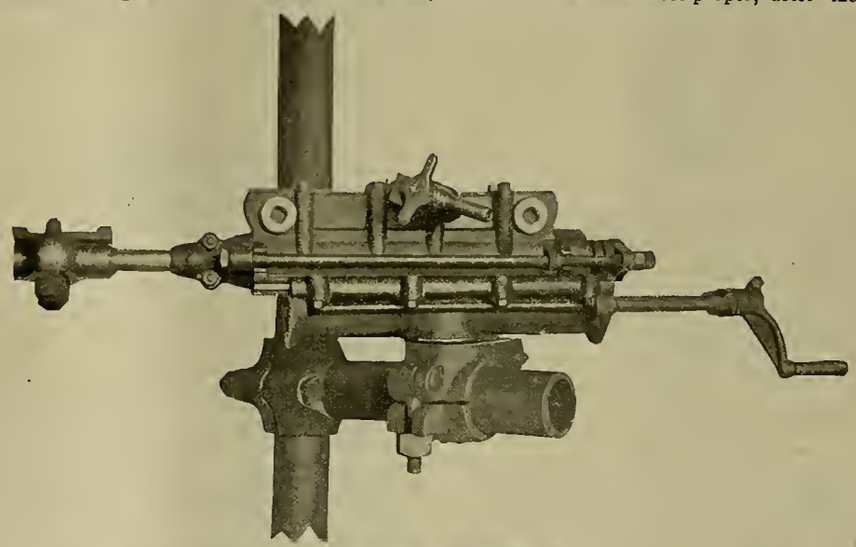
The scheme is the creation of Stone & Webster, an engineering firm of Boston, Mass., the electrical apparatus being furnished by the General Electric Co. and the hydraulic equipment by the Pelton Water Wheel Co. of San Francisco, Cal.

Sinking a Shaft in Quicksand by the Freezing Process.

Sinking of a shaft in quicksand at the Laura and Vereeninging Colliery, in Limburg province, Holland, has been accomplished. The shaft is 270 feet deep to the coal measures and 15 feet inside diameter. It is described by the Iron and Coal Trade Review as follows:

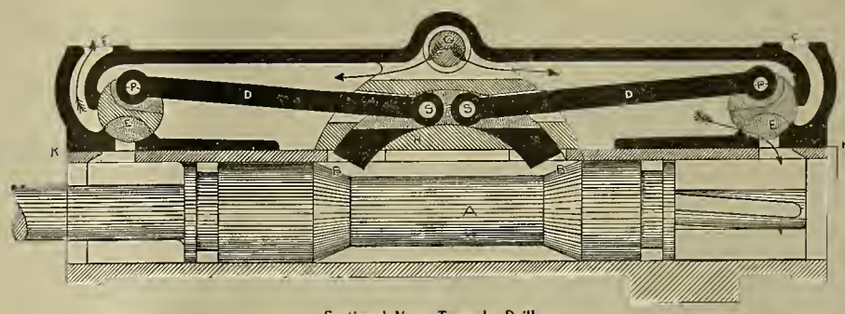
At first a temporary shaft, with a diameter of about 30 feet, was sunk to a depth of 28 feet, and was provided with a provisional timbering consisting of planks and rings of channel iron. From the bottom of this shaft twenty-four boreholes were made, intended for the reception of the freezing tubes. These holes were sunk on the periphery of a circle with a diameter of 24 feet, so that the freezing tubes were at a distance of about 36 inches from each other. They are of a diameter of 4 or 4½ inches, and accommodate the small descending pipes, which only measure 1¼ inches across. The latter communicate by means of valves with a distributing ring, and the former with a return ring, introduced in order to be able to regulate the flow of the freezing solution. In the middle of each freezing tube there is inserted an elastic union which admits of its expansion and contraction with the fluctuations of the temperature. The freezing liquor, which consists of a solution of chloride of magnesium, leaves the refrigerators at a temperature of 20° C. and passes into the distributing ring, then down the small descending pipe as far as the bottom of the freezing tube, in order to ascend through the annular space between the pipe and the tube, until it reaches the return ring, from which it is conveyed by a pipe back again to the refrigerators, where the temperature is once more lowered. By means of the various valves any one of the freezing tubes can be cut out of the system. This operation is rendered necessary when one of them becomes stopped up or leaks.

For the production of the cold there was a double compressor, of which the piston diameters were 5 inches and 7½ inches, and the stroke 18 inches. This machine was driven by a steam engine through the medium of a belt. The carbonic acid was drawn in at a pressure of 220 pounds per square inch and compressed to from 1000 to 1200 pounds per square inch. The compressed and consequently heated gas was next sent through a cooler, where it lost some of its heat, and then was passed into the two condensers in which it was liquefied, and finally the carbonic acid was conveyed through a third condenser to the refrigerators. Before entering the worms of this apparatus, it passed through an expansion valve, which suddenly brought the pressure from 1100 pounds down to about 200 pounds, causing a most intense absorption of heat, or, in other words, the production of intense cold. The refrigerator is a cylindrical vessel with a diameter of 56 inches and a height of 110 inches which is filled with the freezing mixture, consisting of a solution of magnesium chloride 30% strong. The spiral worm tube with the carbonic acid winds inside this vessel and causes the temperature of the solution to sink to 20° C., at which it is pumped into the distributing ring and from thence flows down the freezing tube.



The boreholes were carefully tested to see that they were vertical, for any considerable deviation from the vertical would leave an unfrozen space in the wall of ice. Rotary borers were used and three months' time were required to put the twenty-four holes down. It took eight weeks to freeze a wall of ice 20 inches thick, and at the end of twelve weeks the ice wall was deemed thick enough to begin excavation. The frozen material was excavated with chisels and hammers, a soft unfrozen core considerably facilitating the work. This sinking of 242 feet consumed seventy-five working days, or at the rate of 68 inches per working day. In widening out the shaft in the coal-bearing strata a collapse occurred on the south side, filling the shaft with 40 feet of sand and water. Water is then pumped into the shaft, filling it completely. Twelve more boreholes were driven into the shaft close to the sides, and six more holes on the south side of the shaft and 18 feet from its center. This area was frozen and the work of excavation again begun, and 8½ months after the accident had occurred the bottom of the shaft was again reached.

The Torpedo Drill.

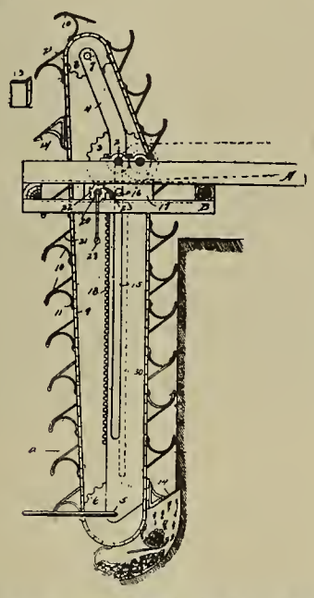


The Torpedo drill is stated by its manufacturer to be the result of development through experiment and experience during the progress of regular mining operations at the North Star mines, Grass Valley, Nevada county, Cal., A. DeW. Foote superintendent, who is represented to have invented the Corliss valve system as applied to rock drills. The Torpedo drill is designed to so act that the full pressure delivered by the hose will be received by the pistor.

By reference to the cut (Fig. 1) the construction and the operation of this drill may be readily understood. A is the piston, which impinges on a circular rocker operating within the Torpedo valve chest, which is bolted to the cylinder on the line KK. The circular rocker is held in position by the bronze guide H, which is readily removed. Attached to the rocker by the pins SS are two valve rods DD, which are attached to the circular valves EE by the pins PP. These circular valves EE are Corliss valves, which fit within steel bushings. These bushings are shrunk into the valve chest proper, after the valve ports have been carefully milled to a template, with intent to make the valve openings accurate. It will be seen that the inclined surfaces BB on the piston, coming in contact with the ends of the rocker, slide the rocker in its seat, and cause the valve to open and close. In this drill the ports are $\frac{7}{16}$ of an inch wide by 1½ inch long. The movement of the rocker is simple and is always in the direction of the motion of the piston. The air is admitted into the valve chest at the opening G, and when the valve is open it passes through the ports, which are about ½ inch deep, into the drill at either end. The exhaust is at the ports F and F on each end of the drill. The valve rods D are made of tool steel, are light, strong and durable. The valve motion is accomplished with but little power. The Corliss valve short-port system, it is claimed, permits the full pressure to reach the piston. A special feature claimed about this valve motion is that it will cause the drill to run at full speed on any stroke from 2 inches to the full stroke of 5 inches.

It is manufactured by the Rix Compressed Air & Drill Co., No. 396 Mission street, San Francisco, Cal., where one of these drills is kept on the testing block and can be seen in operation. The weight of the machine is 120 pounds, length of stroke 5 inches, and diameter of cylinder 2¼ inches.

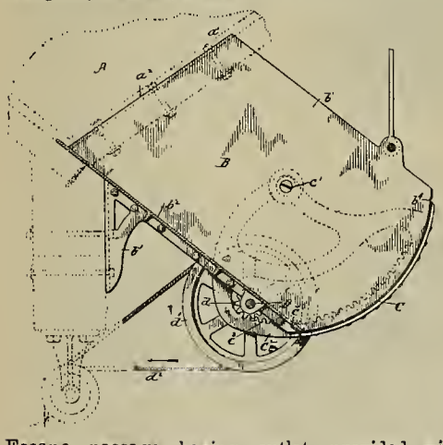
The Torpedo Drill, Set on Column Arm



Sectional View Torpedo Drill.

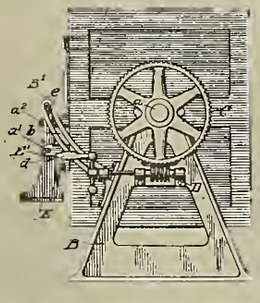
Mining and Metallurgical Patents.

PATENTS ISSUED JULY 21, 1903.



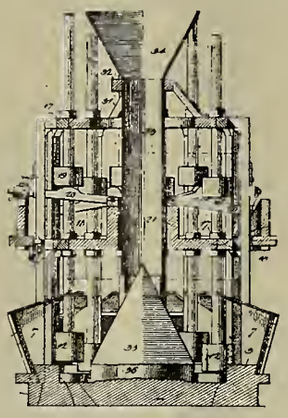
Specially Reported and Illustrated for the MINING AND SCIENTIFIC PRESS.

EXCAVATOR.—No. 733,422; P. J. Raymond, Detroit, Mich.



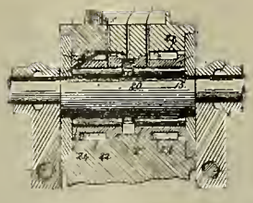
In excavator of kind employing sprocket wheels and chains, bucket secured to chain at advance portion and provided with rearwardly extending brace adapted to contact chain, when bucket is upon straight portion of chain.

GATE FOR COAL OR OTHER POCKETS.—No. 733,623; J. Campbell, Newton, Mass.



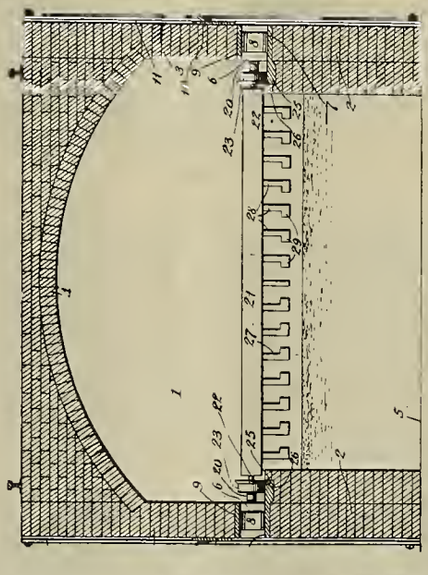
Escape passage having outlet provided with curved side edges, gate for opening and closing same movable in curved path along curved edges or borders and having curved closing plate or bottom and joint sealing abutment at rear end of closing plate or bottom to close against side of wall of passage adjacent to rear lower edge.

FURNACE FOR MELTING METALS.—No. 733,931; J. J. Anderson, South Haven, Mich.



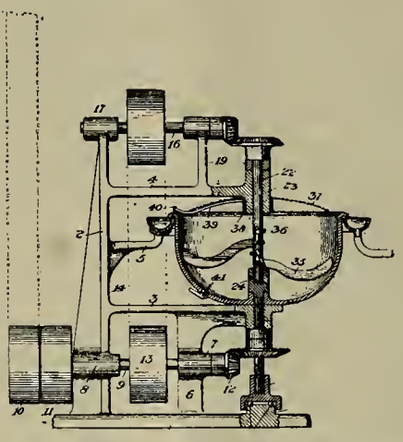
Metal melting furnace comprising closed chamber imperforate at top and bottom and provided with laterally projecting trunnions closed at inner furnace connected ends, supporting frame provided with journals which receive trunnions and support closed chamber, burners G projecting laterally into furnace above body of metal therein, but below top of chamber, air and oil pipes leading to burners and connections for supplying pipes.

STAMP MILL.—No. 733,933; R. J. Baker, El Paso, Texas.



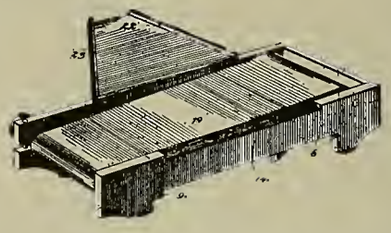
In stamp mill frame including annular upright, plurality levers pivoted radially to upright, cam-shaped projections upon upper sides of levers, vertically movable stamping stems having tappets engaging and adapted to be gradually rotated by cam-shaped projections of levers, rollers upon outer ends of levers, suitably supported annular gear wheel having cams adapted to engage rollers.

CRUSHER.—No. 734,332; T. E. Hurley, Butte, Mont.



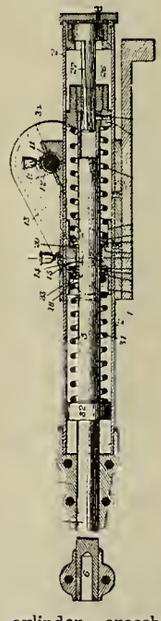
In crusher, frame, fixed jaw, swinging jaw, eccentric shaft having bearings in frame, pitman operated by eccentric shaft and connected with swinging jaw, bushings arranged in pitman head and surrounding eccentric shaft, removable plates on sides of head engaging outer ends of bushings, inner ends of bushings being spaced apart, rollers arranged between bushings and eccentric shaft and spaced apart at inner ends, outer ends of rollers engaging removable plates, collar rigidly secured to shaft at space between bushings and arranged between inner ends of rollers to prevent end movement of rollers, collar having peripheral notches, oil cup on upper side of head, central duct leading from oil cup to space between inner ends of bushings and ducts at opposite sides of central duct and extending through bushings to rollers.

ORE ROASTING FURNACE.—No. 734,104; E. Swain and C. Wood, Iola, Kans.



Combination in ore roasting furnace of side walls comprising lower sections provided at top with cap plates extending longitudinally thereof and covering outer portion of top of each lower wall section, cap plates being thickened at inner edges to form tracks and grooves being provided in lower wall sections adjacent to inner edges of plates and upper wall sections spaced from lower wall sections to form continuous longitudinal air inlet openings.

GOLD SEPARATOR.—No. 733,973; D. C. Knowlton, New York, N. Y.



In gold separator, combination with supporting frame, parallel horizontal shafts supported in bearings of frame, two vertically aligned shafts supported in bearings of frame and geared to horizontal shafts to be revolved in opposite directions, tank centrally mounted upon lower vertical shaft, and plurality of blades each having compound curvature and adjustably secured to upper vertical shaft to project directly therefrom toward tank walls at variable angles.

ORE WASHER.—No. 733,944; C. Carlson, Joplin, Mo.

In ore separator combination with suitable frame, of table mounted thereiu with longitudinal edges abutting against sides of frame, table being uniformly inclined both longitudinally and transversely, and adapted to travel continuously in direction of longitudinal inclination to discharge separated material, means for delivering material transversely to table at higher side, and means for discharging impurities transversely from table at lower side, whereby material in passage transversely across table will be separated into strata of varying degrees of purity and is delivered in separated condition at lower longitudinal end of table.

ROCK DRILL.—No. 734,364; P. Reinhalter, Philadelphia, Pa.

In rock drill, cylinder, crosshead therein having oppositely located extensions, drill rod passing loosely through crosshead, means carried by crosshead and projecting through slots in casing for reciprocating crosshead, abutments upon opposite portions of drill rod, ball-bearing devices carried upon opposite portions of crosshead and received within extensions, springs interposed between abutments and ball-bearing devices, and means for reciprocating crosshead.

Mining Summary.

Specially compiled and reported for the MINING AND SCIENTIFIC PRESS.

ALASKA.

Work is under way on the 900-foot flume and wing dam for the Juaipa M. Co., near Juneau. The object in building the flume is to turn the course of the creek. A 10-ton derrick will also be built, with mast 90 feet in height and telescoping boom with reach of 90 feet.

Lake Arkell, the new district recently discovered in Alaska, is said to be rich, and hundreds of people are going there. The new strike is on the tributaries of Alsek river, 20 miles from Champagne landing and 30 miles above and north of Mush creek. The distance from White Horse is 120 miles. The creeks are 20 miles from the Yukon river.

In the Chistuchina district the season is late, with much snow yet on the ground. Numerous snowslides have occurred and claim operators are clearing the ground by sluicing the snow through the boxes. It was snowing heavily June 3rd.

No definite information can yet be given concerning the probable richness of the Nizina district. There was yet much frost in the ground at last advices, even in that which has been uncovered, and, notwithstanding the early indications to the contrary, the season is a late one. Practically nothing in the way of sluicing has been done. Most of the gold so far taken out has been taken from crevices and bedrock where easily exposed. No one has done sufficient sluicing to estimate what it will run to the shovel per day.

Dr. J. T. Frizell of Portland, Or., says that on Unimak island, one of the Aleutian chain from which he recently arrived, there are thousands of tons of carbonate of iron.

ARIZONA.

COCHISE COUNTY.

The old Gunsight property, near the Modern mine, is bonded to California men. The ore runs high in copper, silver and lead-shipping ore. There is a shaft 300 feet deep on the property.

Assistant Superintendent French of the Copper Queen at Bisbee says that a small hoist will be put in at the Gardner shaft.

During the middle of June the management of the Higgins Dev. Co., near Bisbee, has located a shaft, built 2500 feet of mountain road, installed a 10x14-inch hoist, an air compressor and drills, and sunk a shaft 140 feet and side drifts commenced.

GILA COUNTY.

The Stevens Co. is working on its property at Garfield. The pump has not been working well, and sinking the winze has been discontinued.

The Sierra de Oro Co. at Clifton, under the mansgement of Crawford & Potter, have begun development. The company will install a power plant, an air compressor and drills.

The Clifton-Morenci district has recovered from the recent strike, and is producing the usual tonnage. The A. C. Co. will put in air drills at their Longfellow mines and the Shannon Co. are installing an electrical drilling plant for driving the Carter tunnel to a connection with workings from the other side of the mountain.

The Dominion Co. is working nearly full capacity.

MARICOPA COUNTY.

(Special Correspondence).—Phœnix will shortly have a mining exchange.

It is reported that Los Angeles, Cal., parties have an option on the tailings at the old Vulture mill-site near Wickenburg. It is claimed that these tailings were cyanided in a very primitive manner and that they will yield good values by improved cyanide processes.

Donofrio & Eddy expect to let a contract for sinking a shaft 100 feet on one of their claims, 8 miles west of Frog Tanks. The ores carry gold, silver, lead and copper.

G. Hamlin of the Relief mine, 15 miles north of Peoria, says development work is progressing favorably.

The Illinois Copper Co., near Wickenburg, expect to resume work as soon as it becomes cooler.

The Pike's Peak G. & C. M. Co. are working their property, 12 miles west of Frog Tanks.

Phœnix, July 27.

The Haxworth C. Co.'s group of twenty-five claims at Agua Caliente is reported sold to Chicago and Milwaukee men for $100,000.

MOHAVE COUNTY.

(Special Correspondence).—The Dempsey & O'Dea gold mines at Pilgrim Camp, 9 miles west of Chloride, are bonded to a company of Eastern and Los Angeles, Cal., men for $200,000.

The drift on the 500 level of the Tennessee mine is in 700 feet. Between the 300 and 500 much good milling ore was taken out. Ore in small quantities is yet being found and development is going ahead.

Waddey & Richardson, who contracted to sink the shaft on the Sunrise mine from 140 feet to 240 feet, have nearly finished the work and a good-sized vein of ore is coming in.

The Samoa and Fourth of March mines are producing four carloads of ore monthly. More men are to be put on the former.

It is reported that the Elkhart shaft, down 500 feet, is to be sunk deeper.

The Polar Star mine of Dupont & Hawks is down on the vein 65 feet, showing 90-ounce silver ore, with 1 to 1½ ounce gold. The work of development is suspended until a hoist can be put in.

J. Kay has struck native copper in his claims at Mineral Park.

The Queen Bee mine is working again, after a suspension caused by the Territorial eight-hour law. Twelve men are employed in sinking below 350 feet and driving the drift at the 300.

The Aztec Turquoise Co. have men prospecting for turquoise on their claims and later will have considerable work done.

A milling plant is to be built on the gold claims recently bought by E. R. Holden & Co. of New York, 4 miles west of Kingman. Water for the mill has been secured.

The Mohave G. M. Co. is working more men on their property at Leland and the tunnel on the north side of the hill is being run at the rate of 40 feet a week. The Colorado Iron Works have completed a 40-stamp mill 9 miles below the mines on the Colorado river.

The Gold Roads mine at Acme is outputting ore for its new 300-ton milling and cyaniding plant. Ore is broken by contract for $2 25 per ton.

At Stockton Hill good progress is being made in the sinking of the shaft on the De la Fountaine mine, which is to go down 150 feet below water level before drifting.

Chloride, July 27.

YAVAPAI COUNTY.

(Special Correspondence).—The Hillside mine, 50 miles west of Prescott, is being developed to greater depth under the direction of J. Lawler of Prescott, who, with E. G. Wells, owns the property. Some new ore of good grade has been recently found on the north end of the property on the Seven Stars claim. It is the intention to sink winzes at distances of about 200 feet along the entire length of the vein developed (2500 feet). These winzes will be sunk from 150 to 200 feet in depth by means of a small gas engine. A crosscut tunnel will also be driven in at the south end of the property, at a level lower than the lowest tunnel heretofore run. The mine is equipped with mill and cyanide plant.

Prescott, July 27.

The 40-stamp mill at Octave, in Weaver district, is handling 4000 tons of ore per month, says Superintendent A. E. Hurley. The ore is free milling quartz, running $9 per ton. The mine is developed to a depth of 1200 feet and is equipped with two hoists, a 30-drill compressor and cyanide plant. The property is owned by Pennsylvania men.

G. W. Hull expects to install an electric power plant and electric drills at the Cleopatra mine, near Jerome.

Work will be resumed on the Monte Cristo mine on Groom creek in Hassayampa district, 5 miles south of Prescott. Manager Blauvelt will begin unwatering and developing it.

E. L. Sharpneck will put in a steam stamp on the Blake group, in the same district.

It is reported that Douglas, Lacey & Co. will resume work on the Home Run mine, Hassayampa district.

The Octave mine, in Weaver district, is producing 4000 tons of ore per month, which is treated at the 40-stamp mill. The ore runs from $9 to $13 gold. It is developed to a depth of 1200 feet with twelve levels. There are two hoists, a 30-drill compressor and a cyanide plant. A. E. Hurley and J. R. Leonard are managers.

The new 6-stamp mill and cyanide plant of the Iron King mine, near Val Verde, is in operation. It has a capacity of fifty tons daily. The mines have over 3000 feet of development work, which has all been done within a year. Prospecting is to be continued with diamond drill. B. Blanchard is superintendent.

Upon the application of fifteen different mining companies operating in this county and one private individual, Judge R. E. Sloan has granted a temporary injunction against the Yavapai District Union of the Western Federation of Miners, the McCabe, Walker and Groom Creek mining unions, H. Burns and E. P. Starr, walking delegates, restraining them from in any manner interfering with the peaceful operations of the respective companies named. The defendants are cited to show cause why the injunction should not be made permanent. The injunction is the result of the alleged interference of the union men with the working of some of the properties.

CALIFORNIA.

AMADOR COUNTY.

The Amador Queen mine, near Jackson, is being worked by leasers, who are hunting for pockets. It has produced high-grade arsenical ore.

Crosscutting is in progress at the Oneida, near Jackson, from a drift at the 2200-foot level to cut the ledge 100 feet to the east.

The Shenandoah mine, near Plymouth, on 1000-foot level, run 200 feet on a ledge 130 feet from shaft. This ledge is 25 feet wide. The American E. P. Co is erecting lines through the Plymouth district. When this is accomplished, the Shenandoah will consider the building of a mill.

At the Kennedy mine, near Jackson, the new hoisting machinery is in position. The gallows-frame is being put up. The frame will be over 100 feet in height, and it will be 103 feet from the collar of the shaft to the center of the sheaves. The mill is running steadily, forty stamps dropping in the new mill.

J. C. Williams of Nevada county, vice-president of the Western Federation of Miners, has been in this county several days on business concerning that organization. It is said the object of his visit is to bring the engineers and others identified with the local union of the American Federation of Labor to affiliate with the Western Federation. It is necessary, the latter claims, to hold its position, that all those working in mines in this section should become members, even though they keep up other unions as well. The present center of agitation is Amador City. Superintendents of the Bunker Hill and Fremont mines have been consulted and they fear that trouble is liable to reoccur. Notices have been posted for some time requesting those employed about Amador City mines to become members of the Western Federation. The time limit has been extended to August 10. Notices are posted around Jackson calling a special meeting for organizing engineers, millmen and mechanics as a union under the jurisdiction of the Western Federation. A meeting will be held August 1st.

BUTTE COUNTY.

The Spring Valley hydraulic mine near Cherokee is reported sold to T. L. Vinton of Cherokee.

It is expected that the pumps at the Lecompton mine, near Nevada City, will take ten days to unwater the mine.

The North Bloomfield ditch is to be repaired this fall by building new flumes and replacing old ones and running a 500-foot tunnel through a point where a slide occurred. W. G. Shand is superintendent for Bourne & Co.

Timbers are being cut and roads opened preparatory to starting work at the Jim mine, in God's Country, Eureka township.

The Goldbank quartz mill in Forbestown is to resume work after an idleness of several months.

A 4-stamp mill and 1250-foot pipe line is being built at the Southern Cross mine on the North Fork of the Feather river, near Forbestown. T. Goyne is superintendent.

CALAVERAS COUNTY.

(Special Correspondence).—A run of five and three-quarter days in a 5-stamp mill at the mine of the Maltman G. M. Co. at Angels last week returned $743.97 gold, an average of about $9 per ton. F. Maltman is president and superintendent. The company is about to add ten stamps to the mill.

The Angels Quartz M. Co. of Angels will add twenty stamps to the mill and increase the concentrating plant by addition of new machinery. J. V. Coleman is owner.

At the Kenross mine, at Whiskey Slide, 8 miles from Mokelumne Hill, Superintendent J. T. Thompson says he has thirty men at work, and he expects the stamp mill to be ready for operation next month.

The 10-stamp quartz mill at the Easyz Bird quartz mine of the Emma M. Co., near Mokelumne Hill, started crushing last week. The works are lighted by electricity generated on the grounds.

NEVADA COUNTY.

On the 1600-foot level north of the Champion mine, near Nevada City, a ledge of sulphureted ore has been found in new ground. On the 700-foot level north another ore shoot has been opened, for which work has been in progress for many months, and which was known in upper levels as the Soggs shoot. The shaft of the Champion Co. on the Merrifield now has a depth of 1740 feet. From the 1300-foot level to the bottom it is 16 feet wide, 6 feet high, and has three compartments, one of which is used for the pump column. Above the thirteenth level it has two compartments.

The engine and 10 stamp mill of the Last Chance quartz mine on Diamond creek is being overhauled. A new boiler is also being put in; Bray Bros., bonders.

A 50 ton cyanide plant is to be installed at the Pine Hill mine, Nevada City.

The Brunswick mine is being wired for electric power, which will be installed to run the pumps. The wires are taken through the 700-foot air shaft, at the bottom of which the motor will be established. This will generate power for operating the pumps, which will arrive shortly, when active operations will be resumed.

A 5-stamp mill will be built on the Huron quartz mine, near Omega. W. H. Bray has charge of the work of development.

At the American Hill mine of the Sierra Nevada M. & D. Co., R. Simmons manager, a hoisting works is being erected and a shaft sunk.

The Last Chance mine in Washington township, bonded some time ago by Bray Bros. of Wheatland, will begin work soon. The machinery and 10-stamp mill on the property are being overhauled.

A 20-stamp mill is being built at the California mine on Gaston Ridge, near Washington, L. R. Poundstone superintendent. The mill was bought from the Gold Bank M. Co. at Forhestown.

A strike is reported in the property owned by W. Norton of Nevada City. The mine is in Willow valley, near Nevada City. The leasers, W. Young and R. W. Martin, began work a few days ago, and after putting in their first shot uncovered a ledge rich in gold and heavy with sulphurets. Young & Martin have a two years' lease on the property.

SANTA BARBARA COUNTY.

The Union Oil Co. struck a gushor on July 27.

SHASTA COUNTY.

The converters at the Keswick smelter, closed down since July 2, have been started up again. Two furnaces are now in operation and the third will be running inside of ten days.

The Crown Deep mine in Lower Springs district is to be reopened. The mine is owned by W. P. Miller of Golden Gate, Alameda county. New York men have a bond on the Crown Deep. J. Hume of Redding is superintendent. The ore will be shipped to the smelter of the Mountain C. Co. at Keswick.

SIERRA COUNTY.

The Ruby mine, at Forest City, is reported looking well. For fifteen years this property was worked as a gravel mine, but later a quartz ledge was found which has since been developed with encouraging results. The ore carries free gold and is paying. N. Sanford is foreman of the Ruby mine.

At the Oriental mine in Sierra county, on the north side of the Yuba river, the tunnel is in 2700 feet. It is intended to drive to 3300 feet.

SISKIYOU COUNTY.

A. C. Brokaw of Quartz Valley is working the Golden Eagle mine and mill on Indian creek.

A ditch is to be built from Scott river to Hamburg Bar, Klamath river, for working the hydraulic claims at latter place. It will be 14 miles long and carry 6 inches of water. The ditch will take water from Scott river above Scott Bar. The construction of the ditch will employ 150 men.

TRINITY COUNTY.

Five stamps in the Brown Bear mill are dropping on ore from the Lambeth & Grayson dump, and five stamps are crushing ore from the Lappin mine, under bond to J. J. Chambers of Redding.

Fifty men are employed at the Dorleska mine, Dorleska. H. Z. Osborne is manager.

TUOLUMNE COUNTY.

W. C. Cullers and A. W. Rozier, owners of the Hard Times mine, near Arrastraville, have granted the owners of the Little Beauty mine the right to tunnel through their ground and also to use same as dumping ground.——B M. Hohenshall of Stockton has bought the Yellow Rock quartz mine, near the Newcomer mill, on Knight creek, near Columbia; also, an undivided one-half interest in and to the Fraction quartz mine, on Knight creek, between the Occidental and Sunset claims.

W. C. Stanley has bonded the Handover and Hard Times mines at Arrastraville, near Soulsbyville.

The mill at the Soulsby mine, at Soulshyville, is running and forty men are at work, says Manager W. Sharwood.——A. Harris is putting up a mill on the Vine Spring mine, near Columbia.——The Don-

dero gravel mine at Yankee Hill, near Columbia, has been shut down for the season.

The Harvard M. Co., near Jamestown, in sinking the No. 1 vertical shaft from the 700 level, struck a 15-foot gouge. The shaft was timbered with double sets, one set of timbers being placed 3 feet outside of the regular shaft set, to allow space for easing the timbers. The gouge lies on the serpentine foot wall, which is so soft that it requires to be timbered in the same manner as the gouge. It was estimated that the shaft would continue in this formation for 600 feet, and that each 100 feet would require six men easing timber. Sinking has been discontinued and crosscutting for the vein commenced at the 800 level. It is reported that the shaft will be carried down on an incline on the vein from the point where the ore crosses the shaft, says the Mother Lode Magnet.

YUBA COUNTY.

The Beeney farm of 600 acres, 7 miles east of Marysville and south of the Yuba river, is reported sold at $75 per acre to R. E. Cranston for Michigan men. A drill is in use prospecting the land. The Cranston syndicate owns 1700 acres.

COLORADO.

(Special Correspondence).—Colorado is no nearer a settlement of her labor troubles than when they first started. In fact, they appear to be growing more serious. The men at the Eilers plant, Pueblo, have notified the Trust that they will go on strike July 26, which would close three of the Trust's plants—two in Denver and one in Pueblo. The Trust has notified its patrons to ship no more ore, as they are unable to handle same. The closing of these plants may mean the building of independent smelters—something Colorado needs. The closing of the smelters will also mean the closing of some of the mines throughout the State, as the mines are dependent upon the smelters to market their ore.

Colorado is favored with a special session of the Legislature. The Governor has asked for an appropriation bill to be passed. One was "passed" at the regular session but declared illegal. It is thought the Governor will call a second extra session to pass an eight-hour bill. Should such a law go into effect it would undoubtedly compel many of the unprofitable mines to close down. In many of the camps the miners are only working eight hours and mill men twelve hours.

Denver, July 25.

BOULDER COUNTY.

Work at the Ben C. Lowell group of mines at Magnolia, operated by C. H. Cheney and W. H. Hirshfield is going ahead. The ore shows free and rusty gold, as well as tellurides, and in the breast of the main drift a vein of ruby silver is reported struck. Development work is being done in the 325-foot level, stoping and drifting. They propose to build a mill this fall, as the ore can be treated by cyanide. Machine drills driven by steam are used in drifting.

At Sugar Loaf the Livingston is in operation. The mill has been overhauled and shipping will be resumed, says Superintendent W. Niles. —— The Great Western M. & M. Co. are getting ready to build their mill. Shipments continue.—— The Recluse mine is shut down.

The Eagle Rock Co., near the Cochrane mill, W. Capp of Denver manager, is driving a crosscut tunnel in Sugar mountain, in 800 feet.

CLEAR CREEK COUNTY.

Additional rolls and other machinery are being put in at the dry process mill at '94 tunnel at Alice, 12 miles from Idaho Springs, says G. W. Possell, manager of the company. The remodeled plant will have a capacity of fifty tons per day and is expected to be in operation in September.

The Josephine group on Spanish Bar, near Idaho Springs, has been sold to the Josephine Con. G. M. & M. Co. The group consists of three claims and the company intend to develop them by sinking the Josephine shaft, which is down 290 feet, to additional depth of 400 feet.

It is reported J. E. Bowden of Idaho Springs has sold the Josephine mine to the Josephine Con. M. & M. Co. for $155,000. The company intends to erect a hoisting plant and mill.

An explosion at the Sun & Moon mine, near Idaho Springs, wrecked the transformer house July 28th, set fire to the oil in the transformers and threatened the destruction of the main shaft house. It is supposed to have been the work of strikers, as this was one of the first mines affected hy the recent strike. There were no explosives kept anywhere near the transformer house.

The Elkins M. & M. Co., operating the Terrible properties at Silver Plume, has engaged J. T. Nicholson and W. Morrison of Idaho Springs to superintend the installment of machinery in their mill, which will have a capacity of 300 tons, to be increased to 500 tons later. B. C. Catren is manager.

A. Anderson, G. Carlson and M. W. Tanner of Idaho Springs have a lease and bond on the Beacon of the West property, near the Waltham, in Russell district. The shaft is down 250 feet. The lessees will clean out the shaft to the bottom, retimber where necessary, and expect to put in a hoisting plant and erect shaft house and continue sinking.

The Cripple Creek Gold Temple Co., operating a lease through the main shaft of the Gold Sovereign Co., have put in machinery, including an air compressor. A new 10x10 gallows-frame, 40 feet high, has been put over the shaft and further improvements planned. The leasing company have finished cutting the eighth level station at 600 feet. With this new level extended they will have an additional 75 feet of stoping ground, which will result in increasing the tonnage 150 to 200 tons monthly. Their low-grade ore averages $40 to the ton, first-class $150.

DOLORES COUNTY.

(Special Correspondence).—At the Emma mill, at Dunton, the company is making tests and expect to put in a cyanide plant. The mill has a capacity of forty tons per day and will be enlarged. R. Keller has charge of the property.

The Dunton Con. Mines Co. has been organized to operate the America group, near Dunton.

Dunton, July 27.

FREMONT COUNTY.

The Canon City smelter has resumed treating about 1500 to 2000 tons of ore monthly from Leadville.

GILPIN COUNTY.

Work is going ahead on the concentrating plant for the Nevada Con. G. M. & M. Co. on King flats, west of Nevada, near Central City, and it is expected to be in operation next week.——The Augusta G. M. Co. resumed operations last week on its tunnel running south from Chase gulch into Winnebago hill.

The Mont D'Oro G. M. Co. has been organized by E. C. Sherman and T. R. Cudahy of Central City to operate the New Century (the Tippecanoe) group of claims, in Quartz Valley district and near the Tucker. They are sinking a shaft and will put in a steam hoisting plant.

HINSDALE COUNTY.

The Tobasco M. Co. has leased the engines and boilers of the Black Wonder mill at Sherman, near Lake City, and is moving the electric generator to the mill, that work may progress at mine and mill until repairs to the pipe line recently damaged are completed.

LAKE COUNTY.

Harris & Miller have men reopening the Criterion and Cleaner mines, near Leadville. The mill is being remodeled with intention of putting in a cyanide process. —— The Red Cross Co., in Buckskin gulch, has resumed development work, says Superintendent G. W. Shelton, part owner.

The O. K. shaft of the Progressive M. Co., on Fryer hill, Leadville, has been opened and shipments of twenty-five tons a day are going to the smelter.

The necessary repair work on the New Monarch shaft is completed and shortly the sinking of the shaft to 1300 feet will be commenced.

The Fitzhugh property has been leased to R. B. Estey and T. D. Kyle of Leadville.

J. & G. Campion have leased the Wells & Moyer placer, on Rock hill, California gulch, and will sink a new shaft 500 feet from the old shaft on the Sequin claim.

The 900-foot drift between the Coronado and the Midas has been completed and the work has been started.

The Cloud City mine at Leadville is shipping iron ore daily to the steel works in Pueblo. The shaft is down 504 feet and a drift is being run from the bottom. There is an upraise in the drift and a good body of ore has been found. Manager Jones says the company will sink a new shaft and make other needed improvements.

The California Gulch M. Co. of Leadville has decided to release the property for two years at a fixed royalty.

J. F. Campion, manager and part owner of the Ibex or Little Johnny mine at Leadville, and G. F. Campion have a lease on the Nisi Prius M. Co.'s sixty acres, comprising the Wells and Moyer placers on Rock hill. Campion is also owner of the Sequin lode, which is included in the consolidation. A shaft will be sunk on the Wells and Moyer to catch the extension of the Rock and Dome ore shoot, and will be located 600 feet south of the Sequin shaft. Heavy machinery will be put in.

MINERAL COUNTY.

Plans are being drawn for the steam plant to be added to the Humphreys mill, near Creede, to furnish additional power during the winter when the water is frozen in the creek, says Manager G. Davis.

The Humphreys mill at Creede is handling 6000 tons of crude ore per month, making a saving of 95% and producing a high-grade lead concentrate, also a 60% zinc product.

OURAY COUNTY.

(Special Correspondence).—The American G. M. Co. is handling 40 to 45 tons of ore per day in its 20-stamp mill, using only fifteen of the stamps.

F. M. Jackson is overhauling the Micky Breen mill, which has been idle for years. A new concentrator is being put in. The company is known as the Tempest-Apex M. Co. They will build a tramway from the Tempest mine to the mill. About 7000 feet of development work has been done on the Tempest. The Apex has produced considerable high-grade ore.

Ouray, July 27.

PARK COUNTY.

The Alma placer, consolidated with the Snow Storm placer, is half way between Alma and Fairplay, and is owned by the Snow Storm Hydraulic Co. It comprises 5000 acres of placer ground. J. Fortune is general manager. This placer is situated in the basin of the Platte river at Alma. The gravel is 50 feet in depth. There are 3½ miles of ditches, supplied with water from the Platte, and over 4000 feet of sluices. It is worked by giants, 900 feet of piping and derricks. This placer has been worked over thirty-five years. Since consolidation with the Snow Storm placer miles of ditches have been added and widened. All buildings and workings are lighted with electric lights.

The Cincinnati placer at Fairplay will start up again. Last year many placer locations were made in Mosquito, Buck and Beaver Creek gulches and preparatory work is going on. The Lowe placer, 6 miles south of Fairplay, is working with full force. W. Bemrose is working his placer in Hoosier gulch, which he located in 1860.

SAN JUAN COUNTY.

(Special Correspondence).—Gladstone is on Cement creek, 9 miles from Silverton, on the Silverton & Gladstone Railroad. Here is located the Gold King mill, which has been in use for a number of years, with several additions, as more room was required. The company intends doubling the capacity of the mill. The mine is on Bonita hill and is worked through shafts and tunnels. They have 2½ miles of underground workings. The main tunnel is in 2500 feet and connects with a shaft 700 feet deep, with two compartments. The ore is hoisted by electric hoist to the tunnel level, 250 feet below the surface, and run out to the mill. They are handling 200 tons of ore per day. The ore is quartz and iron, sometimes with good copper values. It averages $15 to $20 per ton. W. Z. Kinney has charge of the company's affairs at Gladstone.

The Mammoth Tunnel group of thirty-two claims, owned by the Stony Pass M. Co., is reached by the Silverton & Gladstone Railway. The tunnel is 7½x8½ feet in the clear, with double track. This company owns eight claims on Stony Pass, Green mountain, 6 miles from Silverton, and will build a mill on the property. A. A. Brown is in charge.

The Yankee tunnel, owned by the Boston & Silverton M. & R. Co., is in 1800 feet and the Lamont tunnel 710 feet. The company owns forty claims. They have a mill and will run as soon as enough ore is blocked out to keep the mill employed. C. W. Swett of Boston, Mass., is president and A. A. Lamont manager.

Gladstone, July 27.

(Special Correspondence).—The Brooklyn M. Co., in the Red Mountain district, is working its properties. Seven hundred feet of development has been done and they are operating a 5-stamp mill and milling fifteen tons per day, also shipping two cars of ore per week to the smelter. F. Manion is superintendent.

Chattanooga, July 27.

A streak of tungsten ore has been struck in the Tom Moore tunnel, near Silverton, at depth of 300 feet.

The Gold Queen Mines Co. has sold the Silent Friend and Mattie B. groups of fifteen claims in Minnie gulch to S. Shaw of Denver.

SAN MIGUEL COUNTY.

(Special Correspondence). — The Alta Mines Co., on Silver mountain, near Ophir Loop, have been doing experimental work the past two years and have about 1 mile of tunnel work on their claims. They have a 20-stamp mill on the property, using vanners and bumping tables, and are now installing a slime table. A. C. Koch is manager.

The Ophir Con. G. M. Co. are operating their 50-stamp mill, handling 175 to 180 tons per day. They will drive a tunnel which will cut the vein 900 feet lower than the present tunnel. L. G. Homfeld is superintendent of the mill and H. S. Buckley assistant manager of the company.

About ninety tons of ore are being put through the 30-stamp mill of the Butterfly-Terrible G. M. Co. They are making about nine cars of concentrates per month. The main tunnel is in 3000 feet. A 1500-foot aerial tramway transports the ore to the mill. The mill is operated by water power, but the company intends installing a steam plant to run the mill during the winter, and also heat the plant by steam. J. McMahon has charge of the property.

Ames, July 21.

(Special Correspondence).—The Yellow Mountain M. Co. are handling twenty-five tons of ore per day with their 10-stamp mill. The capacity of the mill will be doubled. This company is the owner of the old Caribou mine. At present working on the Caribou vein. The main tunnel is in 2000 feet. They have three claims—Caribou, Montezuma and Capitan. W. Davidson, superintendent, states they expect to double their working force. They are now employing twenty-five men.

J. Real has a lease on the 40-stamp mill of the Suffolk G. M. Co., handling sixty tons per day. The mine of this company is under lease. The company is interested in the Badger tunnel, through which, when completed, it is expected to reach all of the fifteen claims of the company.

G. R. Dolf, manager of the Milwaukee-Ophir M. Co., states they have completed an upraise of 480 feet between the Deadwood tunnel level and the old Nevada workings and will build a mill. The Nevada has been idle since 1884 owing to water in the mine. This has now been overcome. The property lies east of the Caribou, on Yellow mountain.

G. B. Pickett has charge of the Carhonero mine, doing development work. The upper level is in 600 feet on the vein and the lower crosscut 500 feet. Ore is carbonate and galena, with silver and gold. They are shipping ore by the carload.

Ophir, July 21.

(Special Correspondence).—R. W. Davis, Jr., manager of the Menona M. & M. Co., is operating the old Columbia 30-stamp mill and shipping ten to fifteen cars of concentrates per month, getting from $8000 to $10,000 gold on the plates. He states they have enough ore blocked out to run the mill three years.

The Tomboy G. M. Co. are shipping 700 tons of concentrates per month. A portion of the old mill is idle, hut the sixty stamps in the new mill are dropping steadily. D. A. Herron is superintendent.

The Silverton M. Co. has a tunnel in 2500 feet in Sultan mountain and will continue it several thousand feet farther. Twenty-three hundred feet from the mouth they have a 110-foot shaft. At the shaft they have a 50 H. P. electric hoist. Work at level No. 8 is being done by contract. They have recently found a good body of ore. The company is repairing the mill and will put in an engine, boilers and generator. J. C. O'Neill is general manager and R. J. McCartney superintendent.

The Hercules Con. G. M. Co., T. Kane manager, will start up shortly. It is the intention to double the capacity of the mill. This company has 3½ miles of underground workings. The property is on Sultan mountain.

Smuggler, July 26.

The annual report of the Butterfly-Terrible G. M. Co., operating at Ophir, issued under date of July 10, shows 717 feet of tunneling driven, 178 feet being in the main tunnel and 539 feet on the east drift. An upraise has been made to connect tunnels Nos. 1 and 3, which is 320 feet in height. Since finishing the upraise a stope 350 feet by 20 feet has been cut and 300 feet of timhering done in the east drift. There are four ore shoots on the east side of the upraise and three on the west. During the producing period, between May 1, 1902, and June 26, 1903, there was shipped to the United States mint 1126.26 ounces of bullion, containing gold values of $16,772.78, and silver values of $137.64. In addition there was shipped concentrates worth $2925.21. C. Bullock of Denver is president.

M. Robbins, foreman of the Smuggler-Union mines, and E. Field have leased the seventy-six claims and all dumps below the Smuggler dump in Marshall basin, owned by the Smuggler-Union M. Co., and are building a 10-stamp mill.

The Smuggler-Union M. Co. is sinking the Mendota shaft 600 feet to the ninth or Bullion tunnel level.

A plant for driving compressed air drills is being installed at the Liberty Bell crosscut tunnel, near Telluride, and the property will be equipped with air drills.

TELLER COUNTY.

(Special Correspondence).—The Cripple Creek drainage tunnel is within 300 feet of completion and should be finished fully two weeks ahead of contract time. Its ef-

fect on the mines is already noticeable.

Cripple Creek, July 27.

The Bonnie Neil plant on Raven hill, Cripple Creek, resumed last week under Lessee Sidell.

G. Jordan has bought the cyanide mill and machinery on the Ironclad claim on Bull hill, Cripple Creek, and is moving it to the Summit mill at Gillett, where Jordan has a lease on the tailings of the Summit mill. The Ironclad cyanide mill has six tanks and this number will be increased.

Rice & Stone of the Stratton estate propose to build a 100-ton cyanide mill, to be erected on Ironclad hill, Cripple Creek, near the offices of the Stratton estate The mill will treat the low-grade ore which it is expected will be mined from the leases on Ironclad, Globe, Womack and Bull hills.

T. McManus of Victor has secured a $20,000 bond and two-year lease on the Glenwood, Oro Cash and the Doonan claim, near Victor, on Howell mountain.

The C. O. D. at Cripple Creek has been considered a worked out mine. T. B. Burbridge sank the shaft to 1000 feet, near the present water level. In drifting underneath the old ore shoot he broke into 4 feet of $80 ore, showing gray copper.

Out of twenty-three deep shafts in Cripple Creek district which had ore at all, nineteen have gnod ore in the bottom levels and most of these bottom levels are near the present drainage level, says G. J. Bancroft. Many of the shafts had lean ground for two or three levels. The number of strikes near the present water level is noticeable. An unusual number of strikes have been made at this horizon, which also marks the limit of the evidences of oxidation. Possibly the water stood at about this elevation at some time in the past.

Work is to be resumed on the Newell tunnel under Beacon hill, near Cripple Creek. Manager W. C. Newell proposes to start work 2200 feet from the portals of the tunnel and cut the Prince Albert, Beacon and Eureka claims. The Newell tunnell has been closed down for a number of months. The resumption of work in this tunnel will benefit several properties in that vicinity.

J. W. King is building a cyanide plant on the Sioux Falls property on Spring creek, near Cripple Creek.

IDAHO.

BOISE COUNTY.

At the Hard Scrabble mine, at Bernard's, owned by J. and W. H. Daly, E. H. Ross and O. McCallister of Meridian, they have men on development work, and have built a wagon road from the mine connecting with the State wagon road at Cape Horn, a distance of 12 miles.

The Twin Sisters mill near Quartzburg has been closed down, it is said, because it does not save the values closely enough. Silver predominates, but the ore carries $5 in gold. H. McConnell of Boise is president.

BLAINE COUNTY.

A 10-stamp mill is being hauled out to the Rosetta district, on the Little Smoky, C. C. Rauthrauff superintendent.

ELMORE COUNTY.

The Elmore mine at Rocky Bar will be reopened by a company of Pittsburg, Pa., men. I. E. Rockwell is manager and M. Leech is superintendent.

IDAHO COUNTY.

(Special Correspondence).—The Moose Creek Placer M. Co. is incorporated at Grangeville, C. P. Richardson, president and manager. The company proposes to enlarge and extend the ditches on the property, install enlarged hydraulic plant and either derrick plant or cableway for boulder handling.

The Buckeye M. Co.'s property at Newsome has just made a cleanup from the season's run of about 100,000 cubic yards. No figures have been given out by the management as to values in the ground. The ground lies advantageously for cheap and rapid hydraulicking. The banks reach a height in present pit of 120 feet. R. L. Phillips, formerly superintendent at Moose Creek placers and American Eagle (quartz), is superintendent. About fifteen men have been employed.

Newsome, July 25.

Work has been started on the Dewey Extension group near Ronsevelt, Thunder Mountain district, by Spokane men, including M. Wolfe and J. Meyers. R. Strang says the season's rush to Thunder Mountain has begun and a number of men are outfitting at Stites for the trip.

Manager F. Macey of the Iron Springs M. Co. on Rapid river, near Warren, says a hoisting plant is being put in to sink a double-compartment shaft. A sawmill is also being set up to cut lumber for the buildings.

MICHIGAN.

HOUGHTON COUNTY.

Commencing Aug. 1, the capacity of Red Jacket shaft at the Calumet & Hecla mine at Calumet will be 1500 tons of rock daily. If the Calumet & Hecla propose an increase in its output, it will be from this source in preference to the shafts on the Osceola lode, which in the past have shown lower values. It is understood all of the company's inclined shafts are to be provided with 7½-ton capacity skips. One of these has already been put in at No. 7 Hecla, the daily output from this source being 700 tons.

The work of installing the hoist for No. 4 shaft at the Baltic mine of the Copper Range Con. Co., north of Painesdale, is about completed and is expected to begin permanent service next week. —— The compounding of the heads at the Champion mill is reported showing a reduction of 30% in the coal consumption.

It is expected the fourth head at the Trimountain mill, at Edgemere, will be ready for operation Aug. 1, when the Trimountain will stop rock shipments to the Arcadian mill.

The improvements under way at the Red Jacket shaft of the Calumet & Hecla during the past year are about completed. The last of the mine bins is finished. Ten days will be required to make the necessary alterations in the shaft and rock house, and during this period the shaft will not supply any mill rock. The nine-ton skips, which are to supersede the cages, are in readiness, by use of which the hoisting capacity of the shaft will be doubled. The mine outputs nearly 6000 tons daily. Bins have been provided at each alternate level, commencing at the 57th at either side of the shaft, and their capacity of nine tons is equal to that of the new skips to be used. The skips are box-shaped, and in the matter of their hoisting and lowering there will be no deviation from the present method. The advantages anticipated are a saving in time of loading and discharging and the hoisting of heavier loads. The engines can hoist a ten-ton load at the rate of 3600 feet per minute, and, allowing for reduced speed at the top and bottom of the shaft, round trip to extreme depth can be made in five minutes.

It is reported that the Michigan will be shipping rock to the Mass mill in October. The shaft rock house at the A shaft of the Michigan has been enclosed and sheathed. A smaller structure on the B shaft is started and will be completed within sixty days. The hoist for the A shaft is on the ground and the 40-drill compressor will be delivered by October.

C. H. Taylor, consulting engineer in charge of the hydraulic plant being constructed at the Victoria, says the automatic compressing plant will be of 4000 H. P.

MISSOURI

JASPER COUNTY.

Material for a 300-ton mill is being delivered at the Independence mine on the Guinn land, north of Webb City. A blanket sheet of ore was developed on this lease and the incline shaft was sunk to 235 feet. M. B Conkey is the manager.

The Obert M. Co. has completed a 100-ton mill at Duenweg.

A company composed of C. T. Bunce, S. Ennes, H. M. Metcalf, O. M. Odell and A. Haughton of Joplin has leased the Murphy land at Zincite, a noted producer, but which for several years has been idle and flooded. They will put in a pumping plant.

Only two weeks of this year show a larger zinc shipment than that of last week. The shipment was larger than the output, which was close to 5000 tons, but the shipment was over 5500 tons. The highest price reported paid for zinc was $40 per ton, which price has ruled for weeks, and the basis ranged from $35 to $37.50 per ton of 60% zinc. Lead continued firm at $52 per ton. A year ago zinc sold at $42 per ton and lead at $48 per ton.

MONTANA.

BEAVERHEAD COUNTY.

Work has been resumed in the smelter of the Indian Queen mine in the Birch Creek district.

BROADWATER COUNTY.

Roseberg & Sutton of Helena have leased and bonded the Stray Horse mine, near Winston. Work has been commenced on a concentrator.

F. W. Rossberg, formerly superintendent of the Peck concentrator at East Helena, has a lease and hond on the Stray Horse mine near Winston. He will superintend development at the Stray Horse. There are 4000 tons of milling ore on the dump. A shaft will he sunk on the vein in the lower tunnel, which is in 1500 feet. The mine is opened hy three tunnels, but for the present work will he confined to the lower tunnel. Excavation for a 40-ton concentrator has been finished.

LEWIS AND CLARK COUNTY.

The Mission Peak M. Co., near Helena, which has been running its stamp mill for two years, will add a cyanide plant.

MISSOULA COUNTY.

The Tarbnx M. Co., of Saltese, has the shaft down 400 feet. A crosscut is to be driven 75 feet and the vein drifted. A cage and pumps are being installed.

SILVER BOW COUNTY.

J. O'Leary, secretary and treasurer of the Hidden Lake M. Co. of Butte, says a 100-ton concentrator will be built at that property. The company has nineteen quartz and placer claims, millsites and two water rights on Warm Springs creek.

Nine mines of the Amalgamated Copper Co. in Butte and the Anaconda smelter are to open August 20th. Nearly 5000 men will return to work. The shut-down was caused by making connection between the furnaces and the great flue and stack recently completed.

NEVADA.

ESMERALDA COUNTY.

The mines of the Con. Esmeralda M. Co., 12 miles from Hawthorne, is to have a 40-stamp mill. The plant was originally erected at Jordan, 16 miles from Bodie, a number of years ago, but not used. It includes power drills, air compressor, rock breakers and complete hoist.

It is reported C. H. Elliott of Salt Lake, Utah, has bonded the Chiatovich mine at Silver Peak for $75,000. The property is equipped with machinery and is in operation.

LINCOLN COUNTY.

The Baltimore and Radical claims have been sold to B. F. Lewis and J. H. Gurmann. They adjoin the property of the Parallel G. M. Co., near Searchlight, on the northwest.

An air compressor and new machine drills will be installed by the Ione M. Co., near Searchlight. Two shafts will be sunk, a whip being used preliminary to a hoist; F. A. Spare, manager.

NYE COUNTY.

Reduction works for the Tonopah M. Co. are being considered, to be built this summer at Tonopah.

Superintendent McCarthy, of the North Star mine at Tonopah, reports that the shaft is now down 905 feet and stringers of ore coming in.

The Boston Tonopah shaft is down 300 feet. It is the intention to crosscut at 500 feet; G. S. Nixon, president.

A flow of water has been encountered on the 300 level of the Rescue mine in Tonopah. It is pumped to the surface and sold for various purposes.

The Enterprise M. Co. reports a discovery of tin at their mine at Lone Mountain, 4 miles south of Barrel Springs.

STOREY COUNTY.

Electricity is to be substituted for steam in operating power drills at the Overman mine, Virginia City.

WHITE PINE COUNTY.

The Wild West M. Co. is putting in machinery, offices, ore bins and making other improvements on its property in Egan canyon, near Cherry creek.

NEW MEXICO.

GRANT COUNTY.

W. McAllister has arranged with Edward Steele, of Dallas, Texas, to erect a 60-ton concentrator for the low-grade ores of the Aztec mine in Pinos Altos mountains, near Silver City. The ores contain gold and silver sulphides. The new concentrator will consist of rolls, screens, jigs and concentrating tables.

SANTA FE COUNTY.

The Gold Bullion M. Co. has been incorporated at Santa Fe by R. S. Baldwin, S. Jaros and F. M. Choate of New York. The company will operate in southern Santa Fe county.

OREGON.

BAKER COUNTY.

The Dixie group on Granite Boulder creek, near Sumpter, is to have a milling plant of twenty tons capacity. F. Ray is manager.

The new 5-stamp mill on the I. X. L., F. T. Kelly, manager, has started up. There is sufficient ore blocked out to keep the mill running several months.

Arrangements are being made to install an air compressor and power drills on the Victor, in the Cracker Creek district. This property was taken over recently hy A. G. Hanauer, of Spokane, and is under the management of the Geiser-Hendryx Investment Co., H. T. Hendryx of Sumpter, manager.

The Gold Hill property, near Durkee, operated hy the Burnt River G. M. Co., was sold to Nicholas Bros. of Portland, Or., for $250,000, of which $25,000 was paid down. The mine has a 10-stamp mill, with rock crusher and four concentrators.

The Quebec mine, in Blue Mountain district, has started up under direction of R. Adams.

A 100-ton mill is to be built at the Golden Wizard, near Sumpter, as soon as ore has been tested. J. M. McPhee is superintendent.

The Single Standard Co., on Paddy creek, tributary to Eagle, near Baker City, Or., will erect a 20-stamp mill on the property, says E. S. Tice of Baker City.

L. O. Miller of Sumpter says the Golden Wizard Co. will build a concentrating plant.

The Listen Lake Co., operating in the McNamee district, has finished an air blast and is grading for a hoist to be put in within a short time.

Mack's Luck G. M. Co., operating in Deer Creek district, is opening up its property.

JOSEPHINE COUNTY.

W. H. Hampton is constructing a tubular hydraulic elevator at Deep Gravel placer.

SOUTH DAKOTA.

CUSTER COUNTY.

The Sunbeam M. Co, near Custer, have a shaft on the vein down 220 feet. The ore is bluish gray quartz, carrying free gold. The company has installed a hoisting plant, consisting of boilers, hoisting engine, an air compressor, pumps, blacksmith shop, sawmill, etc. It is the intention to build a stamp mill, the lumber for which has been sawed.

The Bullion Co, near Keystone, will erect an 80-stamp mill as soon as practicable.

LAWRENCE COUNTY.

J. Conzette, of the Ruby G. M. Co, is erecting a small cyanide plant for experimental purposes preparatory to the permanent plant to be built near Lead City.

The Horseshoe Co. of Deadwood has made a new departure in locating its new mill at the mines on Bald mountain, says the Lead Call. thus saving on transportation of ore. The new plant is expected to drop one-half of its stamps on August first. The building is 424x168 feet, containing 120 stamps, engine, boilers and tanks. Forty feet west, and connected by a covered tramway, is the crusher building, equipped with two No. 5 Gates rock crushers, engine and two boilers of 100 H. P. each, and a bin capacity for 3000 tons. The crushed ore passes from the crushers to a conveynr, which delivers the ore into the mill bins. Coal is delivered by the same process to the boilers in the center of the mill building. The mill bins hold 7000 tons. The tanks are steel and the eight are 40 feet in diameter and 5 feet deep. On the floor below are sixteen tanks 10x20 feet. Lower are eight gold solution tanks 10x15 feet. Still lower are eight sump tanks 12x24 feet and four storage tanks 14x30 feet. The mill is in two sections of sixty stamps. In the center is the engine and boiler of 150 H. P each. The mill is near the Mogul mine and will be supplied with water from the Mogul workings. The Horseshoe Co. will convert the Kildonan mill at Pluma into a wet crushing mill, removing the rolls and substituting sixty stamps, giving it a capacity of 250 tons daily.

PENNINGTON COUNTY.

The tramway from the Ida Florence shaft to the Bismarck mill, near Hill City, is being built, and it is expected to have the stamps dropping next month.

UTAH.

BEAVER COUNTY.

The lead furnace of the Majestic smelter near Milford will be blown in by August 15th, says Manager W. A. Farish, and will treat 100 tons of Harrington-Hickory silver-lead ore per day. For the present the ore will be transported to the smelter by teams, a train or railroad to be put in later—the distance being 4½ miles. The starting of the lead furnace will be followed soon after by the blowing in of the 250-ton copper furnace.

JUAB COUNTY.

Constructing Engineer J. M. Callow and Superintendent Legg of the Uncle Sam Con. M. Co. have called for bids for the construction of the building and supplying machinery for a concentrating mill near Eureka.

The West Tintic M. Co. has been organized at Salt Lake City by A. C. Lee, D. F. Walker, Jr., and H. W. Walker. The company owns a group of four claims in West Tintic district, near Eureka.

R. G. Legg, manager of the Uncle Sam at Eureka, says the company is giving final consideration to the matter of a mill.

The shaft of the Black Jack M. Co., at Mammoth, is down 1100 feet, with 300 more to go to reach the drift from the Lower Mammoth. The Black Jack is putting out iron ore for the furnaces of

the Amsrican S. & R. Co. in Jordan vallsy.

The managemsnt of the Lower Mammoth of Tintic, at Eureka, has mads connection with sach of its main fissurss on the 1200-foot level, with a maximum depth of 1500 feet below the surfacs.

MILLARD COUNTY.

Of the propossd enlargemsnt of the Highland Boy smelter, owned by the Utah Con. M. Co., Mansgsr Channing states that ground will bs broken for the buildings and contracts for the equipment let in August.

SALT LAKE COUNTY.

Connections in ths installation of the new flue at the Highland Boy smelter havs been completed, says Managsr Channing, and 516 tons daily are bsing smeltsd. Twelve roasting furnacss and two largs rsverberatory furnaces are to be added.

S. Bambsrger has deeded the Fortune mine near Bingham to the Bambsrgsr Exploration Co., and also bought ths Evergreen lods, a claim within the lines of the Fortuns group, for $3000. Work is temporarily shut down at ths Fortuns, says the Bullstin.

The St. Jos mine at Bingham has been closed down for an indefinite period, says Manager Hasbrouch, dus to a deal psnding for control of the mine.

The output of the Yampa mins at Bingham, under ths 30,000-ton contract with ths Bingham Con. smelter, is averaging two carloads daily, to bs increassd as soon as connection with ths Copper Belt railway is effected. No stoping has been dons, the ore all coming from dsvelopments.

Ths rscsnt striks reported on ths 1500 levsl of ths Brooklyn claim, of the Bingham Con. M Co, is proving richer than first reportsd. Managsr McVichie is reportsd as saying, in this connection, that the Bingham propsrties ars approaching that stags where increased facilities for smelting and output will become necessary. Ths tunnel is bsing driven and ths water has drawn off, so that it will bs possibls soon to carry on mining in the various shafts.

SUMMIT COUNTY.

Ths Ontario, Park City, is to have a new concentrator of fifty tons capacity. It is to bs located at No. 3 shaft. It will bs run by electricity, says Managsr Root.

At the Silver King Con., ths company intends building a boilsr houss, 35x50, for three sets of boilers. Ons sst of 85 H. P. boilers will bs put in as soon as the building is ready for them. A new gallows frame is to bs erected. A station has been cut on ths 500 lsvel for a duplex compound pump which will havs a capacity of 600 gallons per minute. A new 12x 16 sngins good for 2000 fset will be put in also.

WASHINGTON.

FERRY COUNTY.

At Mount Elsmeham, the Nighthawk tunnsl is crosscutting the vein 65 feet from the hanging wall in soft, granulated quartz and has not struck the footwall.

The Ruby mine, on Mount Chapaca, is employing eight men. Ors is bsing shippsd to ths Everett smeltsr. The Ruby is 12 miles northwest of Loomis.

The Horn Silvsr mine, on Palmer mountain, nsar the Similkamesn river, has a 5-foot vein of silver-bsaring ore. Eight men are employsd; O. P. Tufty superintsndent.

OKANOGAN COUNTY.

J. Boyd is in New York arranging for the installation of a 3000 H. P. electrical plant, and an air compressor, to be placsd at the mine of the Palmsr Mountain tunnsl at Loomis.

Ors from a blind ledge on the lower workings at the Opal mins, near Chesaw, gives high values in gold. Ths ore is 4 fset wide and is running with the tunnel, in 200 fset, and has a vsrtical depth of 90 feet. One hundred feet ahead of the face surface work shows a large body of ors. Treasurer F. L. Woodbridge, of the Opal Co. of Nswark, Ohio, says that a rsduction plant will be placsd on the propsrty.

PIERCE COUNTY.

A contract by which the Southern Pacific Railroad Co. will take the entire output of the Carbon Hill coal mines, is reported closed. The mine is near Tacoma, and its output is 20,000 tons a month. Hitherto a portion of the coal mined has bsen sold to steamship lines.

STEVENS COUNTY.

The Old Dominion 60-ton concentrator at Colville, which has been idle for six years, has been repaired, and operations started. The ore bodies on the Old Dominion have been uncovered. W. F. Kyle, lessse of the property, had twenty-two men during spring and early summer timbering the underground works in various parts of the mine and starting new developments. The latest and most important dsvslopment is ths opsning of 3 feet of chlorids ore in the old Ella shaft.

Work has begun on the Blackthorn claims, in ths Msteor camp, on the Colville reservation. Foreman Matthews rsports the lsdgs widsning. The tunnel was started at the bottom of the canyon and is running in on ths ledge.

Managsr Olmstead of the Stray Dog group is in New York making arrangements for extsnsive dsvslopment work, $15,000 having alrsady been expended on ths property, and it is said that the ledgs contains 26 inches of high-grade ore.

A California company is preparing to run a 3000-foot tunnel from Stray Dog canyon. Survsyors are surveying the site.

The Nonparsil Co. is at work on a 1000-foot tunnel to tap the lsdge at 700 fsst dspth.

FOREIGN.

AUSTRALIA.

NEW SOUTH WALES.

Ths tailings dump of the Wentworth mines at Lucknow are reportsd sold for $50,000.

Ths Nswstead Tin M. Co., at Elsmore, it is reported, has struck a rich tin lode 6 fest in width, ore assaying 25% tin. At Newstead, the tin dsposits are ovsrlaid by basalt from 150 to 200 fest thick, and this has to be sunk through bsfore ths tin-bearing granite is reachsd, and frequently considerable water is found in the shafts.

It is reportsd that ths Amalgamatsd Coppsr Co. has bought the Cobar coppsr mines in New South Wales. The price is stated to bs, with ths adjoining lsases, £1,500,000.

The Central mine, at Broken Hill, is to sink a new shaft (inclined) in the foot wall, all other shafts heretofore bsing in the ore body or started in the hanging wall country. Owing, however, to the extensive undsrground operations, ths ground on the hanging wall has sttled and is constantly shifting slightly, thus rendsring shafts there insecure and expensive to maintain. Ths nsw shaft will be frse from the sffects of "creeps" and othsr disturbances. Ths vsnturs is looked forward to with soms intsrsst, as it is the first shaft to bs thus locatsd in that district, though shafts so locatsd are common elsswhsrs.

QUEENSLAND.

Ths Queensland gold rsturns for ths month of June wsrs as follows:

Mine.	Tons Crushsd.	Yield in Ounces.
Charters Towers	25,400	41,000
Croydon	3,900	4,200
Gympie	15,000	14,000
Mount Morgan	22,500	9,900
Ravsnswood	1,900	4,100
Other fields	5,100	4,500
Alluvial	....	1,000
Total		78,700

Total yisld for six months, ouncs. 438,900

WEST AUSTRALIA.

The Kalgurli Gold Co., at Kalgoorlie, July 3, report: During June treated 3815 tons for a return of 3625 ounces (£14,047) of gold, with expsnditures for month as follows: Working expsnses, £6055; dsvelopmsnt, £655; capital expenditure, £474.

The Murrin Copper Co. report their production for month of June at: Twsnty-three days' smslting ore gave matte containing 120 tons of fine coppsr. It is sxpectsd ths nsw works will be in opsration by Aug. 1.

Shanks Bros. & Gesrke report from ths Victory lsase at Mount Clifford, north snd of Leonora district, having taken 618 ounces from twsnty-sight tons. The avsrags was twenty-two ouncss. This was taksn up in January. A leadsr was found on the outcrop. After doilying for a month, the gold was found on the lower ground, ths three msn getting fifty ouncss of aliuvial gold. The lease was then worked for alluvial, 300 ounces bsing secured by a dozsn msn. The thres msn thsn sank a water shaft 80 feet, and then drove 20 feet towards ths reef and sank to 100 feet, water level. At that depth stone going six ounces was found. There are other shafts, one 50 feet and the other 40 feet, down. It was from these that the latest returns were crushed at the Clifford battery. No stoping has been done.

The Mt. Magnet district of the Murchison Goldfield had up to the end of May last treated 216,561 tons of ore for a yield of 210,667 ounces; average, .97 ounce.

Following is the cost of operating at the Vale of Coolgardie during May: Stamps at work, 10; days running, 28; stone crushed, 1015 tons; duty psr stamp per 24 hours, 3 6 tons; bullion obtained, 336 ozs. 16 dwt. 23 grs.; aversge per ton, 6 dwt. 14 grs. Expenses—Mining per ton, 14s. 3d.; milling per ton, 8s. 3d.; development, per ton milled, 20s. Cyaniding — Tailings treated, 1066 tons; bullion obtained, 78 ozs. 6 dwt. 12 grs.; average, 1 dwt. 11 grs. Expenses—Cyaniding per ton, 4s. 3d. Total for month, 414 ozs. 2 dwt. 11 grs; average, 8 dwt. 5 grs. Total yield to dats, 55,390 tons for 35,266 ozs. 1 dwt. 4 grs.; general average, 12 dwt. 21 grs.

The South Kalgurli mins has bssn clossd, throwing 200 men out of smployment. The mine has besn stsadily working at a loss. Ths intsntion is stated to bs to raise additional capital to provids an enlargsd equipmsnt, in order that the mins may bs opsrated on a larger and more economical scale; J. Iiss, manager, Kalgurli.

BRITISH COLUMBIA.

ATLIN DISTRICT.

A company compossd of B. C. Warnick, P. Russ, S. Presssr, A. Buchanan and A. L. Solenburg of Pennsylvania, with H. W. Knight of Overbook, Or., are putting in a gold dredging plant at Atlin. The timbsrs for this drsdger wsrs obtained in Vancouvsr.

BOUNDARY DISTRICT.

The Boundary district has shippsd over 300,000 tons of ore this ysar, and the tonnage ssnt to the smeltsrs ths past month is the greatsst for sevsral months, being above 15,000 tons.

The Oro Denoro has joined the shipping list, ths ore going to the Sunsst smelter.

The Morning Glory shippsd thres cars of ore last wesk.

At Fairview, sevsnty msn ars employed in the Stsmwindsr mine, mill and cyanids works. The mill runs twsnty-five to thirty-fivs stamps, according to ors output.

Work has bsen startsd on the Trilby in Skylark camp, recsntly bonded by Gaunce & Wickwire of Grssnwood, McDonell brothsrs of Anaconda, and A. J. Coursen of Ssattle.

Work on the North Fork wagon road to Franklin camp is bsing rushed.

Eight furnacss ars in blast in the thrss Boundary smsltsrs, trsating 3000 tons of ore daily.

On the Quesn of Shsba claim at Dsadwood, G. Andrews is taking out fine looking ors. He is now down 25 feet in an incline on ore between lime and porphyry. L. A. Smith of Anaconda and G. Andrews own the property.

Tsn cars of ors havs bssn shipped from the dump of the Morrison mine, Deadwood. It is expsctsd that 1000 tons will be shipped.

Five more stamps will shortly bs addsd to ths mill of ths Waterloo mins, Camp McKinney.

It is expectsd thsre will be six furnacss in operation at the Granby smelter at Grand Forks by Ssptsmbsr 1, says H. N. Galer, assistant manager of the Granby Co.

At the Wakefield mine work is going ahead in both mins and mill. The concentrator is bsing remodeled under Superintendsnt G. King of Spokane, Wash., and whsn completed will handle 150 tons of ore psr day.

CARIBOO DISTRICT.

The Rambler-Cariboo mins, near McGuigan, will put in a compressor 2 miles from the mins, at which point by fluming two cresks an ample water supply can be obtainsd.

EAST KOOTENAY DISTRICT.

The Crow's Nsst Coal Co. has dscidsd to build its new offics in Fsrnie. On the last pay day at Crow's Nsst mines, a total of $130,021.05 was paid out at the thrss camps, an increase of $14,817.25 over any previous monthly payroll.

Ten of ths nsw coks ovens are ready for uss at Morrissy.

W. Blakemore of Nslson reports the iron propertiss, in which hs is interested, at the hsad of Crawford creek, in East Kootenay, carry a good grads of spscular iron. A 6-foot lsad has bssn opsnsd up and developmsnt work is being done. Ths group is 5 miles from Kootenay lake, with which connsction could be made by an aerial tramway. The coal fsilds of East Kootenay are also within easy rsach.

KAMLOOPS DISTRICT.

One hundrsd thousand dollars is to bs furnishsd by the Ashanti Lands, Ltd., an English concern, to install a plant to treat the ore of the Iron Mask at Kamloops.

Two new furnaces are being installed at Granby smelter, making a total battery of six. The connections with flue-dust chamber and blowers are to be made in a few days, when the plant will be closed down for a week.

LARDEAU DISTRICT.

The Eva stamp mill is nearing completion and the towers of the tram line are being erected.

The free gold vein on the Stockholm mine has been traced 1000 feet.

Messrs. Brock and Boyd of the Dominion Geological Survey are making a geological survey of the Lardeau district, of which a map will be issued by the department. The survey will take in the mineral belt from Fish crsek to Kootenay lake, including the country around Camborne, Trout lake and Ferguson.

ROSSLAND DISTRICT.

At the White Bear mins, nsar Rossland, the directors will expsnd $40,000 in buildings and plant, including a concentrator, and $10,000 to $15,000 in devslopment. A 20-drill compressor plant is undsr way. A 250 H. P. hoist has also bsen ordersd and the hsadworks to contain ths nsw hoist will bs shortly started.

J. Cronin, manager of the St. Eugsne Con. M. Co., operating at Moyis, B. C., will put in more power and add an engine to run the mills and will also put in zinc concsntrators.

At the Spitzse mins, nsar Rossland, the compressor and hoisting machinery are in opsration and underground work again under way. Two shifts ars carrying the main shaft down from the 100-foot station.

SLOCAN DISTRICT.

The minss in Slocan and Ainsworth districts are sither starting work or incrsasing thsir forcss, due to the lead bonus.

W. Hunter is working the Comstock. Ten inchss of ore has bsen expossd on the surface bstwssn No. 4 and No. 5 tunnsls.

The concentrator at the Wakefield is being remodelsd and will have a capacity of 150 tons psr day.

A strike is reportsd on the Black Hawk, of the Mansfield, at the head of the South Fork. Ths vsin is 6 fset wide, carrying a 10 to 14-inch paystreak.

The first shipment of three cars of zinc ore from the Lucky Jim, under ths manags msnt of Mr. Jonss, has bsen mads. This is one of the sarliest discovsrsd Slocan propsrtiss.

The iron deposits at the hsad of Crawford crssk, owned by B. White and J. Dsvlin, are to be worksd, as ths bonus granted on iron and steel by the Dominion governmsnt will enable thsm to work at a profit. The ore is spscular iron.

Managsr J. F. Collom of the Arlington mins at Slocan lake has made application to ths gold commissionsr for 400 inches of watsr to bs taksn from Springer crssk, this being preliminary to the sstablishmsnt of a mill for ths trsatment of Arlington ores.

At the Wakefisld mine ths concsntrator is bsing rsmodeled undsr ths supsrvision of G. King of Spokane.

Ths Rossland World says the Northwsstsrn has its stamp mill ersctsd and the Oyster-Critsrion and Eva are sach building 10-stamp mills.

COREA.

American msthods are said to have revolutionizsd the mining industry in Corsa. The Oriental M. Co, at Wunssn in northsrn Corea, nsar the Manchurian bordsr, 300 miles north of Chemulpo, havs bsen putting in an extended mining and milling plant. Americans ars said to have the best concessions in ths kingdom, and havs dons more work than any othsr foreign country in dsvsloping the minsral rssourcss of Corea. J. T. Forth of San Francisco, Cal., has installsd for ths Orisntal Co. one 40-stamp and ons 80-stamp mill, ons of these at Mayburg mine and ths other at Taraco. The English will start up a 30-stamp mill on their concssion next wssk.

KLONDIKE.

O. F. Brenner, manager of the Klondike-Dstroit Co., opsrating the Williams concession on Hunker cresk, has two stsam shovels on the road to Dawson, and intends to bring ssvsn or eight if the two first prove a suocsss. G. L. Taylor, the Indian river and Bonanza opsrator, has installsd a stsam shovsl.

The Yukon Council has decided to allow the minsrs a prior lien on 50% of ths sntire output of the Klondike mines. A supplier of wood is given equal right with a laborsr on the mins proper in ths prior lien on 50% of the output. A olause to the effect that labor may havs a lien on 50% of the product, unless an agrssment is signsd to the contrary, was stricken out. A laborer has ths right to a lisn on all the product of the mine when there are no prior mortgages or other prior incumbrancss, but up to 50% of the product he has priority over all manner of incumbrances.

MEXICO.

CHIHUAHUA.

J. Follensby and W. Kraft have bought the Nueva Chihuahua mine, near Chihuahua, for $50,000, Mexican, cash. The property comprises forty-four pertenencias.

DURANGO.

(Special Correspondence).—Regular operations continue in the mines and the smelter of the Fernando M. Co., in the San Fernando mountains near San Fernando. In the smelter are three calciners (two reverberatories and one mechanical—the column and arms of which are water-cooled instead of air-cooled) and two re-

verberatory smelting furnaces. The principal values in the ore are in gold, with copper and silver. After concentration, the sulphides are calcined and smelted up to 50% to 55% matte, which carries 30 to 35 ounces gold and 200 to 300 ounces silver. In the mine the lowest workings are through No. 5 tunnel. Preparations are being made to sink from this level, for which an electric hoist is on the ground. Electric power is generated by turbines operating under a 20-foot head. H. H. Taft is manager.

San Fernando, July 19.

JALISCO.

The Las Moras M. Co., G. E. McCormick, president, has over 3000 feet of development on its property at Ameca. The ores are low-grade copper, great quantities being shown by development. It is the intention to put up a large concentrating plant.

The Jose Moreno mine, 2 miles south of Guanajuato, is reported sold for $325,000. R. Morrison is manager.

SONORA.

(Special Correspondence).—The Yaqui S. & R. Co.'s plant, situated in the foothills of the Sierra Madres, on the west bank of the Yaqui river, 80 miles east of Minas Prietas, was visited by a tornado on the evening of July 11, which did great damage to unfinished buildings and construction rigging. Part of the roof of the large silver refinery was destroyed. Cables parted in the riggings, relieving the main supports, and but for prompt action of the employes the damage would have been much greater. For many months the company have had freight wagons hauling hundreds of tons of machinery, material, merchandise and supplies from the railroad, 80 miles away. All of the season's supplies have arrived, also most of the machinery. The plant when running will have a blast furnace capacity of 125 metric tons daily, while the refinery will take care of the bullion products of 300 tons of ore. The plant is so arranged that the smelting capacity can be increased by adding more stacks. The plant is modern in every detail and especially designed to smelt, reconcentrate and refine the products of silver-lead and copper ores and their by-products. All furnaces of whatever character are steel water-jacketed and provided with blast. Even the furnaces for melting bullion have the brickwork inclosed within steel water jackets, to protect the operator from excessive heat. The smelting plant will be equipped with machine shop, electric light, two-story sampler and an ice plant. In addition to the regular brine freezing tank, the plant will be provided with a water tank containing refrigerating coils to maintain the temperature of the water at nearly the freezing point to supply the employes. As a result of establishing a large smelting and refining plant so far from the railway, in the heart of the extensive anthracite coal and natural coke fields of La Barranca and Pilares, and adjacent to many mines, aggregating great quantities of all kinds and characters of ores, and where graphite, clay, pure iron ores and limestone can be had in unlimited quantities, a great ore market can be built up. At the present time it costs on an average about $50 per ton, United States gold, for freight and treatment charges on ores shipped out of the country, but with an ore market established in the heart of the mineral belt the conditions will be changed in favor of the miner. The transportation expenses on the ores to market have, as a rule, retarded development work, with the exception of work on the bonanza mines, where the ore was high grade.

Toledo, Sonora, July 16.

The Gold Treasure mine, 9 miles southwest of Naco, in San Jose mountains, has been sold to the Arizona M. & D. Co. of Oklahoma City, O. T., which owns the Gladstone & Big Medicine property in Colorado. A 20-stamp mill will be put up. The mine is within 6 miles of the railroad and has an available supply of wood and water.

It is stated that the Nahuila group of San Javier is bonded for $65,000 gold, and the Belene of San Javier for $75,000. The former is the property of the Guterrez M. Co. and the latter of Flores Bros.

The Congress of the State has approved the executive contract with the Bufa M. & S. Co., for the establishment of a reduction plant in the Sahuaripa district.

C. F. Wren, of the Alsacia D. Co., is at the mines near Cananea making arrangements for development work. He says a smelter will be built. The mines are in the Ajo mountains, 35 miles southeast of Cananea, and carry silver, lead and copper.

At Toledo the boilers for the Yaqui S. & R. Co. have arrived. The making of fire brick has begun, says the Nogales Oasis.

The Sonora Dev. Co., E. S. W. Drought manager, at Nacozari, has its 10-stamp mill, 5 miles from that place, almost completed.

The new 40-stamp mill of the Zublate M. Co. is completed.

ZACATECAS.

The mines of the Asientos district, Aguascalientes, produce about 400 tons of ore per day, the value ranging from $30 to $55 per ton. One of the mines, the No Pensado, has yielded in two years, it is said, $250,000 net profit.

PERSONAL.

J. B. FARISH has returned to Denver, Colo., from Mexico.

F. L. BOSQUI is examining cyanide propositions in Okanogan county, Wash.

J. HUME is superintendent of the Crown Desp mine near Redding, Shasta county, Cal.

GEO. L. CARR is in charge of the Yellow Rosa mine, at Dorleska, Trinity county, Cal.

G. SNYDER is in charge of the Balaklala copper mine of Shasta county, Cal., vice W. W. Adams.

FORMER COV. PECK, of Wisconsin, is inspecting mining interests in the Pearl district, Idaho.

N. SANFORD is superintendent of the Ruby mine at Forest City, Cal., vice R. Evans, resigned.

D. M. GRAY of the Canyon City, Colo., smelter, is in Leadville, Colo., buying ore for his company.

H. M. STANLEY is superintendent of the Sierra mine near Groveland, Tuolumne county, Cal.

H. C. ERMANN of the Compromise M. Co. has returned to Hermosillo, Mexico, from Nogales, Ariz.

S. DAVIS of Redding, Cal., is superintendent of the Old Spanish G. M. Co., in Shasta county, Cal.

W. W. ADAMS has resigned as manager of the Balaklala copper mines at Kennett, Shasta county, Cal.

CHAS B. WORES has returned to Los Angeles, Cal., from an examination of Nevada mining property.

W. H. PLUMMER has returned to Spokane, Wash., from the Le Roy group, near Elk City, Idaho.

R. ADAMS is superintendent of the Quebec mine in the Blue Mountain district, Baker county, Or.

O. REUTER of Chicago, Ill., is in the Black Hills of South Dakota, investigating the mining industry.

H. FULTON is superintendent of the Pittsburg Tunnel M. Co in the Thunder Mountain district, Idaho.

GEO. S. NIXON, president of the Boston-Tonopah M. Co., of Tonopah, Nevada, is in the East on business.

J. BOYD of the Palmer Mountain Tunnel Co., near Loomis, Wash., is in New York on mining business.

H. W. TURNER, E. M., has returned to San Francisco, Cal., from inspection of mines in Trinity county, Cal.

C. W. PURINGTON, who has been examining properties near Lake City, Colo., has returned to Denver, Colo.

H. T. HENDRYX has returned to the Victor mine, near Sumpter, Or., from a business trip to Spokane, Wash.

W. J. HOWARD of New York is in the Blue Mountain district, Baker county, Or., to examine mining properties.

GEORGE C. GILL, president of the Shannon Copper Co., has left Clifton, Ariz., for his home at Holyoke, Mass.

R. C. LEGG, manager of the Uncle Sam mine, at Eureka, Tintic district, Utah, has returned to the mine from Wyoming.

C. M. COLEMAN is general manager of the Keystone placer mine on the San Miguel river, San Miguel county, Colo.

L. H. CARVER, E. M., of San Francisco, Cal., has returned from Plumas county, Cal., where he has been inspecting mines.

F. L. WOODBRIDGE, treasurer of the Opal mine, near Chesaw, Wash., has returned to Newark, Ohio, from the mines.

JOHN LAWLER, owner of the Hillside mine, in western Yavapai county, Arizona, has returned to Prescott from the mine.

HENRY A. SALZER AND A. PLATZ of La Crosse, Wisconsin, have left the Gold Coin M. Co.'s properties at Black Lake, Idaho.

GEO. E. LAWTON is superintendent of the Houghton Development Co., operating the Solomon Springs group, near Bisbee.

G. MAULESS, an ore buyer for the American S. & R. Co., has returned to El Paso, Texas, from an extended trip in Mexico.

W. J. DOOLY, manager of the Johnny mine in the Stateline district, Utah, has gone to Bishop, Cal., to examine mining property.

R. K. CAMERON of Chicago, representing the Allis-Chalmers Co., is investigating the Poplar Creek gold fields, above Kaslo, B. C.

MANAGER OLMSTEAD of the Stray Dog mines on the Colville reservation, near Colville, Wash., is in New York on mining business.

J. JEWELL is in charge of the Kansas City Gold Reef M. Co.'s properties on Monumental creek, in Thunder Mountain district, Idaho.

ROSS E. BROWNE, E. M., has returned to San Francisco, Cal., from Placer county, Cal., where he has been on professional business.

F. RAY, manager of the Dixie group of mines, near Sumpter, Or., is in San Francisco, Cal., for the purpose of buying milling machinery for the mines.

R. EVANS, formerly superintendent of the Ruby mine, near Forest City, Sierra county, Cal., is now superintendent of the Taper mine, Plumas county, Cal.

A. G. LARSON, E. M., of Rossland, B. C., has been engaged to examine the Homestake properties, south of Rossland, with a view to their further development.

B. GOODWIN, C. F. HUMPHREY, J. MEYERS AND C. CHRISTIANSEN, officers of the Murchie Con. M. Co., were in Nevada City, Cal., last week, inspecting the mine.

J. P. EVANS is in charge of the construction of the smelter at the Eva May mine, owned by the Montana Mineral Land D. Co., Basin, Jefferson county, Mont.

J. T. FORTH has returned from the mines of Corea to San Francisco, Cal. He has been in Corea the past three years installing machinery for the Oriental M. Co.

G. SNYDER, of Salt Lake City, Utah, is manager of the Balaklala copper mines of the Balaklala Con. C. Co., at Kennett, Shasta county, Cal., vice W. W. Adams resigned.

H. C. MORGAN of Cuba, N. Y., president of the Columbia Menona mines in the Savage Basin, near Telluride, Colo., and A. M. Wellman of Friendship, N. Y., are at Telluride.

C. H. SPINKS of Berkeley, Cal., has been appointed superintendent of the Mertell M. Co., which is installing a plant near Livermore, Cal., to develop magnesite deposits there.

G. W. MEYERS, representing the Chrome Steel Works of Brooklyn, has returned to San Francisco, Cal., from Calaveras county, and leaves for a trip East on business next week.

GEO. B. LEE, superintendent of the new smelter recently completed at Douglas, Ariz., by Phelps, Dodge & Co. of New York, is at Grand Forks, B. C., investigating smelting methods at Granby.

W. L. MCLAUGHLIN is general manager, E. Marion superintendent of mines, C. C. Griggs superintendent of mill, and J. Hartgering master mechanic, of the Horseshoe M. Co. of Deadwood, S. D.

H. H. ANDREWS is to have charge of the construction work for the Oregon Electric P. Co., erecting the power plant on Eagle creek, east of Baker City, Or. A. B. Frame is manager for this company.

A. S. DWIGHT, E. M., has returned to Cananea, Mexico, from Rio Tinto, Spain, where he went to investigate mining and metallurgical methods in vogue there. Mr. Dwight is metallurgist for the Green Copper Co. of Cananea.

C. H. WHITE, E. M., instructor in mining and metallurgy at Harvard University, Cambridge, Mass., is conducting the geology class through the principal camps of Colorado. They will remain in Colorado until August 8, when they will return to Denver and thence East.

Commercial Paragraphs.

THE California office of the Colorado Iron Works Co., Denver, Colo., is 510–511 O. T. Johnson Bldg., corner Broadway and Fourth Sts., Los Angeles, Cal.

Catalogues Received.

"Assayers' and Chemists' Supplies" is the title of a 312-page catalogue 7x10 inches, from the Denver Fire Clay Co. of Denver, Colo., the ninth edition, with new features, classified, illustrated and accompanied by detailed explanation. Anything and everything used by the assayer or chemist is designed to be duly represented, the book being a finely printed compendium of information on many points of interest to any one connected with mining or metallurgy. Part I is devoted to illustrated description of chemists' and assayers' laboratory supplies; Part II to special chemical apparatus for analytical work; Part III, outfits for assayers and prospectors, school sets of chemical apparatus, collections of minerals, models and charts, scientific books; Part IV, fire brick, tile and fire clay material; Part V, chemicals and pure reagents; Part VI, physical apparatus. There is, besides, considerable general information.

Obituary.

DR. WILBUR CLINTON KNIGHT, professor of geology and mining engineering in the University of Wyoming, and curator of the State Museum, died July 29th, of peritonitis, at Laramie, Wyo. He was born at Rochelle, Ill., December 13, 1858, and was graduated from the University of Nebraska.

New Patents.

DEWEY, STRONG & CO.'S SCIENTIFIC PRESS PATENT AGENCY, 330 Market St., S. F., has official reports of the following U. S. patents issued to Pacific coast inventors:

FOR WEEK ENDING JULY 21, 1903.

734,212.—METAL SIGN—Ayers & Coffee, Modesto, Cal.

733,936.—TENSION DEVICE—J. Barrett, Tombstone, Ariz.

734,327.—SULPHUR BURNER.—H. Blumenberg, Jr., Daggett, Cal.

733,940.—VEHICLE SPRING—F. Bosch, Crescent City, Cal.

734,039.—BOTTLE—L. Brand, Los Angeles, Cal.

734,400—CASH DRAWER—H. H. Cheshorough, Seattle, Wash.

734,408.—WRENCH—H. G. Dunston, Santa Monica, Cal.

734,056.—RAILWAY RAIL JOINT—J. W. Gay, Sodaville, Or.

734 342—NAPKIN HOLDER—L. R. Le Lande, S. F.

734,076—PIANO TRUCK—A. Loeh, Portland, Or

733,983.—CAN BODY MACHINE—A. Lotz, S F.

734,237—GAS ENGINE—J. D. McFarland, Jr., S. F

734,238—DEPURATOR—A. W. Ottignon, Seattle Wash.

733,996.—WINDOW SHADE—M. E. Reilly, Tacoma, Wash.

733,999.—PLOW—Richards & Gitman, Tacoma, Wash.

734,243.—FLAT IRON STAND—Mary Schuhbert, Los Angeles, Cal.

734,284.—FRUIT BRUSHER—F. Stehler, Riverside, Cal.

734,145—PRESSURE APPARATUS—F. Swinney, Tucson, Ariz.

734,021.—CAR—Warner & Gilman, Tacoma, Wash.

734,110—LUMBER DRIER—G. X. Wendling S. F.

734,385.—WATER GATE—L. Winans, Hood River, Or.

Notice of Recent Patents.

Among the patents recently obtained through Dewey, Strong & Co.'s SCIENTIFIC PRESS U. S. and Foreign Patent Agency, the following are worthy of special mention:

GAS ENGINES.—No. 734,237. July 21, 1903. J. D. McFarland, Jr., San Francisco, Cal. One-half assigned to John Bruckman, of same place. This invention relates to improvements in explosive engines in which the cylinders are mounted radially with relation to an axis and in which their piston rods are connected to a shaft eccentric to this axis. One object of the invention is to obviate the leakage of gas and loss of power usual in the engines in which the inlet and exhaust valves are located contiguous to the crank shaft and wherein the admission and exhaust take place at the inner end of the cylinders. Another object is to confine the attachment of the piston rods to the crank shaft within the narrowest possible limits and to provide for take up when these bearing parts have become worn. These improvements are applicable either to an oscillating or revolving cylinder engine.

METAL SIGNS.—No. 734,212. July 21, 1903. E. L. Ayers and Wm. F. Coffee, of Modesto, Cal. Ayers assigned interest to Coffee. The object of this invention is to provide an indestructible sign suited particularly for use in indicating localities, directions and distances along highways. A further object is to provide a form which will hold a plurality of sets of directions indicating as many different places, distances, etc., and which will admit of one set or any letter or part thereof being removed or replaced at any time without having to dismantle the entire sign. A sign board of this character is not liable to injury or defacement by vandals and is practically indestructible.

Latest Market Reports.

SAN FRANCISCO, July 31, 1903.

METALS.

SILVER.—Per oz., Troy: London, 25 3/8d (standard ounce, 925 fine); New York, bar silver, 54½c, refined (1000 fine); San Francisco, 54½c; Mexican dollars, 42½c San Francisco, 42½c New York.

Silver shows no appreciable change since last week, though somewhat higher during the week than the above quotation.

COPPER. — New York: Standard, $13.25; Lake, 1 to 3 casks, $13.00@13.25; Electrolytic, 1 to 3 casks, $13.62½@13.75; Casting, 1 to 3 casks, $12.75; San Francisco: $13.00. Mill copper plates, $17.00; bars, 18@24c. London: £57 7s spot per ton.

Copper shows a still further, though slight, decline. There is no new or unusual feature in the copper market.

Following are the figures of the German consumption of foreign copper for the months January-May, 1903, compared with the same period of 1902 and 1901, in tons:

	1903.	1902.	1901.
Imports	36,223	33,971	27,344
Exports	4,739	3,748	3,783
Consumption	31,484	30,223	23,561

LEAD.—New York, $4.25; Salt Lake City, $3.50; St. Louis, $4.00; San Francisco $4.50, carload lots; 4½c 1000 to 4000 lbs.; pipe 5½, sheet 6, bar 5½c; pig, $4.75. London: £11 5s per long ton=2.75c per lb.

SPELTER. — New York, $5.87½; St. Louis, $4.85; London, £20 2s 6d per ton; San Francisco, ton lots, 6½c; 100-lb lots, 7c.

ANTIMONY.—New York, Cookson's, 9½c; Hallett's, 8½c; San Francisco, 1000-lb. lots, 10c; 300 to 500 lbs., 11c; 100-lb. lots, 13@15c.

TIN.—New York, pig, $27.25@27.50; San Francisco, ton lots, 29½c; 500 lbs., 30c; 200 lbs., 30½c; less, 31c; bar tin, ℔ lb, 32½c @35c. London, £125 5s spot.

PLATINUM.—San Francisco, crude, $18.00 ℔ oz.; New York, ingot, $19.00 per Troy oz Platinum ware, 75@80c per gram.

QUICKSILVER.—New York, $44.50@46.00; large lots; London, £8 15s; San Francisco, local, $44.50 ℔ flask of 76½ lbs.; Denver, $49.50. Export, $43.50.

BABBITT METAL.— San Francisco, No. 1, 10c; No. 2, 7c; No. 3, 6½c; extra, 17½c; genuine, 35c; Eclipse, 37½c.

ALUMINUM.—New York, No. 1, 99% pure ingots, 35c; No. 2, 90%, 30c to 34c.

SOLDER. — Half-and-half, 100-lb. lots 19½c; San Francisco, Plumbers', 100-lb lots, 16c.

NICKEL.—New York, 50@60c ℔ lb.; ton lots, 45@48c.

STRUCTURAL MATERIALS.

IRON.—Pittsburg, Bessemer pig, $19.50 @19.85; gray forge, $18 60; San Francisco, bar, 3c ℔ lb., 3½c in small quantities.

STEEL.—Bessemer billets, Pittsburg, $28.00@29.00; open hearth billets, $29 00; San Francisco, bar, 7c to 12c per lb.

LUMBER.—(Retail): Pine, ordinary sizes, $20.00@22 00; extra sizes higher; redwood, $22.00@23.00; lath, 4 feet, $4.25 @4.50; pickets, $19.50; shingles, $2.35 for No. 1 and $2.00 for No. 2; shakes, $13.50 for split and $14.50 for sawed; rustic, $26.00 @32.00.

NAILS.—Per keg (list prices): No. 20d to 60d, Wire, $3.25; Cut, $3.35; 10d to 16d, Wire, $3.35; Cut, $3.35; 8d, Wire, $3.40; Cut, $3.40; 6d and 7d, Wire, $3.50; Cut, $3.50; 4d and 5d, Wire, $3 60; Cut, $3.60; 3d, Wire, $3.75; Cut, $3.75; 2d, Wire, $4.00; Cut, $4.00. Special rates for carload lots.

LIME.—Santa Cruz, $2.25; Roche Harbor, $2.25 per bbl.

CEMENT. — Germania, $2.50 @ 2.75; Hewmoor, $2.90; Trowell, $2.90; Portland, $2.50@2.75 per bbl.

GENERAL SUPPLIES.

POWDER.—F. o. b. San Francisco: No 1, 70% nitro-glycerine, per lb., in carload lots, 15½c; less than one ton, 17½c. No. 1*, 60%, carload lots, 13½c; less than one ton, 15½c. No. 1** 50%, carload lots, 11½c; less than one ton, 13½c. No. 2, 40%, carload lots, 10c; less than one ton, 12c. No. 2, 35%, carload lots, 9½c; less than one ton, 11½c. No. 2** 30% carload lots, 9c; less than one ton, 11c. Black blasting powder in carload lots, minimum car 728 kegs, $1.50 per keg; less car lots, $2 per keg.

CAPS.—3x, $5.50 per 1000; 4x, $6.50; 5x, $8; Lion, $9, in lots not less than 1000.

FUSE.—Triple tape, $3.60 per 1000 feet; double tape, $3.00; single tape, $2.65; Hemp, $2.10; Cement No. 2, $3.00; Cement No. 1, $2.65, in lots of 3000 feet and up.

CANDLES.—Granite 6s, 16 oz., 40s., 10½c ℔ set; 14 oz., 40s., 9½c.

CHEMICALS.—Cyanide of potassium, 98%-99%, jobbing, 24@25c ℔ lb.; carloads, 23@24½c; in tins, 35c; soda ash, $2.00 ℔ 100 lbs.; hyposulphite of soda, 2½@2¾c ℔ lb.; caustic soda, in drums, 3@3½c ℔ lb; Cal. s. soda, bbls., $1.25@1.50 ℔ 100 lbs.; sks., $1.05; chlorate of potash, 12@13c; nitrate of potash, bbls., 10c; caustic potash, 10c in 40-lb tins; borax concentrated, 7@8c ℔ lb.; roll sulphur, 4@6c; powdered sulphur, 2@3c; flour sulphur, French, 2@3c; alum, $2.00@2.25; California refined, 2@2½c; sulphide of iron, 9c ℔ lb; copper sulphate, 5@7c; chloride of lime, spot, $2 50@2.75. sulphuric acid, in carboys, 66% B, 2½c ℔ lb.; nitric acid, in carboys, 8c ℔ lb.

WHITE LEAD.—Per lb., in kegs: 500 lbs. and over at one purchase, per lb., 6c; less than 500 lbs., per lb., 6½c; in 25-lb. tin pails, ½c per lb. above keg price; in 1 and 5 lb. tin cans, 100 lbs. per case, ½c per lb. above keg price. Dry Lead—In bbls., 1 ton and over, 6c; do. in kegs, 6½c.

RED LEAD.—500 lbs. and over at one purchase, per lb., 6c; less than 500 lbs., 6½c.

LITHARGE.—Pure, in 25-lb. bags, 8 @9c per lb.

BONE ASH.—Extra No. 1, 5@6c per lb. No. 1, 4@5c.

BORAX.—Concentrated, 7@9c per lb powdered, 9@12c; fused, 25@30c.

BORAX.—Crystal, 7c; calcined, 25c.

MANGANESE.—Pure, ℔ lb., 60c.

SODIUM.—Metal, ℔ lb., $1.00.

MOLYBDENUM.—$2 per lb.

CHROMIUM.—(90% and over) per lb., $1.00.

BISMUTH.—Subnitrate, per lb., $1.60.

MERCURY.—Bichloride, ℔ lb., 90c.

PHOSPHORUS. — (American) ℔ lb., 75c.

SILVER.—Chloride, ℔ oz., 90c@$1.00; nitrate, 55c.

ALUMINUM.—No. 1, 99%, small lots, 37c ℔ lb.; 100 lbs., 35c; 1000 lbs., 34c; ton lots and over, 33c, Pittsburg. No. 2, 90%, small lots, 34c; ton lots and over, 31c, Pittsburg.

URANIUM.—Oxide, ℔ lb., $3.50.

ZINC.—Metallic, chemically pure, ℔ lb, 50c; dust, ℔ lb., 10c; sulphate, ℔ lb., .04c.

(These prices are wholesale, f. o. b. San Francisco, unless otherwise noted.)

HELP WANTED.

Required for Copper Mines in Arizona

employing about 250 men, young mining engineer of good technical education and some experience in mining and mechanics, to act as assistant to superintendent. Address SHANNON COPPER CO., Clifton, Ariz.

Desks

Three entire floors of our spacious new building devoted entirely to show samples of office furniture. Call and see the latest style desks and other labor-saving conveniences.

Office and Bank Fixtures
A SPECIALTY.
ESTIMATES FURNISHED.
Call on Us or Send for Catalog. It Will Pay You.
Geo. H. Fuller Desk Co.,
646-650 MISSION ST., SAN FRANCISCO.

Montana State School of Mines,
BUTTE, MONTANA,
—AND—
Four-Year Courses in Mining Engineering an Electrical Engineering.
Fall Semester opens September 14th, 1903.
For Catalogues or other information, address
N. R. LEONARD, President.

COPPER MINES
Near two railroads; 300-ft. vein; large amount of ore shipped; area ¼ mile by ¾ mile. A good interest will be given for 300 to 500 ft. working shaft, or diamond drill work. Address Agent, this office.

SITUATIONS WANTED.

ASSAYER AND CYANIDE MILLMAN DESIRES position. References. Address "Assayer," care of Mining and Scientific Press.

CHEMIST AND ASSAYER DESIRES POSITION in mine or refinery. No objection to foreign countries. Address V.J.H., this office.

EXPERT DIAMOND DRILL FOREMAN AND Setter of twenty years' experience in various parts of the world. At present employed, but desires change and a permanent position in the West. Can bring one or two operators as desired. Address "Diamond," this office.

FIRST-CLASS MINING AND LAND SURveyor, Draughtsman, etc., desires position. Address H. W. K., Box 74, Long Beach, Wash.

MINE SUPERINTENDENT WANTS POSITION with a substantial company that has a mill on property. A qualified mining engineer who can run a mine or mill, cyanide plant, assaying and surveying. Address "Mining," this office.

MINING ENGINEER AND METALLURGIST, at present general manager of a large mining concern in Mexico, desires to change his position. Would need four months' notice. Address F.B.A.S., care of this office.

WANTED — POSITION BY EXPERIENCED Millman; 18 years' experience in operating jigs, Frue vanners and Wilfley tables. Best references furnished. Address F. L., care of this office.

TO COPPER MEN.

An experienced copper metallurgist would arrange to change from present engagement upon suitable representations

Is thoroughly familiar with all details of operation of large smelting plants, the handling of labor, etc., and would consider a proposition to engage as superintendent or metallurgist of plant already in operation, or to design and erect contemplated works, or act as consulting engineer.

In replying please give as fully as consistent details of location, salary, proposed terms of contract, etc., which will be treated as strictly confidential.

Address "Amargosa," care of Mining and Scientific Press.

WANTED.

CAPABLE ENGINEER OF GOOD STANDING and experience would like to purchase an interest in an established engineering business—mining or civil. Only a business capable of expansion and doing high grade work is desired. Address "Experience," care of Mining and Scientific Press.

WANTED--MILL TAILINGS,
Gold, silver or lead, in New Mexico, Arizona or old Mexico. Will buy or lease. Give location, quantity and value. A. E. VAN VELSAN, Telluride, Colorado. Box 181.

Backing Desired to Look Up Mining Properties.
References exchanged. Address "R", this office.

WANTED—Nitrate of Soda Deposits on the Pacific Coast.
Address "Nitrate," Mining and Scientific Press.

WRITE TO US
For Competent
TECHNICAL MEN
For all classes of work.
5000 positions filled in 10 years.
Engineering Agency
210 Monadnock Block, CHICAGO.

FOR SALE.

FOR SALE--Established Custom Assay Office in Yreka, County Seat of Siskiyou.

Cheap for cash. A snap. Reason for selling—affected eyes. Address Alden J. Steele, Yreka, Cal.

FOR SALE.—Good interest in a copper and gold property; 160 acres, near R. R. in California. Large quantity of ore shipped; last shipment 28.45% copper, $9 50 gold and silver. Fine ore supply. One-half purchase price from mine, balance easy cash payments. Fine property for incorporation. Address "Manager," this office.

Tonopah Claims for Sale.
I have several good prospects for sale, located in known mineral belt in Tonopah mining district. Groups suitable for incorporation. Claims $100.00 to $250.00 each. Correspondence solicited.
Address WALTER OSBORN,
BOX 309, TONOPAH, NEVADA.

LILLOOET, FRASER RIVER & CARIBOO GOLD FIELDS, LIMITED.
In Liquidation.
List of Properties to Be Sold by Private Tender, Pursuant to the Directions of the Liquidators.

Trout Lake Mining Division.

ALPHA GROUP (better known as "Broadview Group"), comprising 9 Crown-granted mineral claims, or fractional claims, situated on Great Northern mountain, above Ferguson, B. C., together with two blocks of land, namely: Lot 1144, situated just west of Ferguson townsite, and lot 2419, situated about 2 miles northeasterly from Ferguson on the North Fork of Lardeau river, at the foot of Great Northern mountain.

LANDS situated on Galena Bay Upper Arrow Lake. Three blocks of land comprising, in all, about 650 acres.

Rossland Camp.

The "CITY OF SPOKANE" and "NORTH STAR" mineral claims, together with the buildings and equipment thereon.

Boundary District.

The "NETA" mineral claim, Crown-granted, situated in what is known as "Brown's Camp," and the "QUEEN OF SPADES" mineral claim, Crown-granted, situated in what is known as "Central Camp."

Illecillewaet Mining Division

The LANARK GROUP, comprising 15 Crown-granted mineral claims, or fractional claims, situated on the main line of the Canadian Pacific railway, near Illecillewaet, B. C.

Parties desiring to put in a tender for any one or more of the above mentioned properties should have their engineer on the ground, and examination made, without delay.

Further particulars and conditions of sale and forms of tender (which are to be sent in not later than August 15th, 1903,) may be obtained gratis of the Liquidators, College Hill Chambers, College Hill, London, E. C., and J. V. Armstrong, Revelstoke, British Columbia.

Dated June 15th, 1903. July 31.

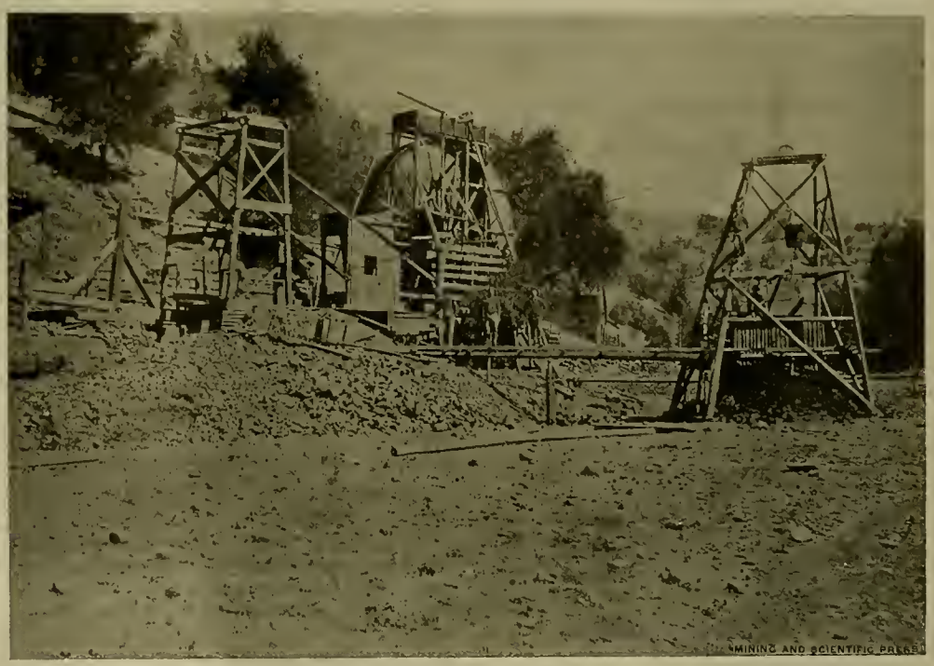
Whole No. 2246.—VOLUME LXXXVII. Number 6. SAN FRANCISCO, CAL., SATURDAY, AUGUST 8, 1903. THREE DOLLARS PER ANNUM. Single Copies, Ten Cents.



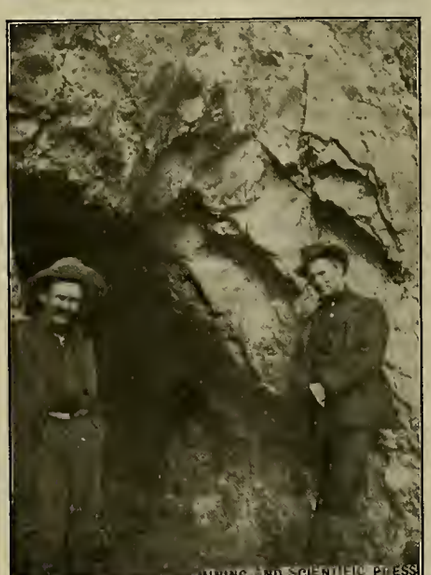
The Ingenious Prospector.

The average prospector is a man of original ideas, and often very good ones. If they do not always bear the stamp which characterizes the work of the trained engineer, the prospector's mechanical schemes usually are, at least, thoroughly practical and show the possession of a good fund of that very desirable capital, good sense. He is a man who can generally adapt himself to varied and often adverse circumstances and conditions. About the only thing that is "too much for him" when funds are low is a volume of water with which he cannot successfully contend with limited resources, but it is often a matter of surprise to see the amount of water he can take care of with makeshift arrangements. The "jackhead" pump is a favorite with him, and he can build one if needs be, provided he can secure the necessary materials and tools. If he cannot do this, he bails vigorously as long as he can make headway in sinking, but not infrequently he is obliged to give up the unequal contest by reason of lack of means to secure better machinery. He constructs his head frame of peeled round poles, if he cannot afford to buy sawed lumber. The structure may not be a "thing of beauty," but it is substantial and usually answers every requirement. Unable to buy boiler and engine, he builds a water wheel with his own hands and turns to his use and benefit the natural power of a neighboring stream or ditch. To the crank of the overshot wheel he attaches his "jackhead." The wheel may also be utilized to hoist rock from the shaft, or even to run a mill.

In the early days of California mining overshot wheels were to be seen throughout the mining region, and some of these were of great size—as large as 60 feet diameter—though usually 28 to 32 feet. These developed a greater or less amount of power, according to diameter and width of the breast. They are still in evidence in numerous isolated places, mining arrastras, pumps, mills and hoists.

For ventilation he employs all sorts of devices—home-made fans, water blasts and air sails, or drives an upraise to secure natural ventilation. He is "onto all the tricks of the trade" and knows how to apply them. The result is not always success—that is, financial success—but he makes headway, and no one can deny that he makes a mechanical success, and he does it with a minimum of capital other than practical ideas and willing, skillful hands.

The accompanying illustration shows clearly the equipment of a mine with a home-made outfit. The head frames are constructed of round, peeled pine poles. A little lumber has been used in building the ore bin, flume and wheel, but none has been wasted. The "direct-acting" jackhead may be seen at the left shaft, the rod near the top of the triangular structure (the bob) running back to the wheel crank. The water that runs the wheel is piped across the valley and is carried up to the top box through the pipe shown in the illustration. The shafts are provided with surface aprons to insure the safety of men below when the bucket is being dumped, and everything is arranged in workmanlike manner. The entire plant shows ingenuity and practical sense, and is a fair illustration of what may be done by a man having these with limited ready cash. This is only a single example of the ingenuity, perseverance and ability of the prospector to combat adverse conditions, and the mining industry owes much to him.



Typical Prospectors' Head Frames and Outfit.

Ten-Stamp Mill at La Cumbre, Packed in by Mules.

Result of Violence.

The miners who were ordered out of Idaho Springs, Colo., by a committee of citizens for alleged participation in the blowing up of the transformer house of the Sun and Moon mine, near that city, have appealed to Governor Peabody for military protection; but the Governor has replied that the expelled miners must seek redress in the courts of Clear Creek county, as he has no jurisdiction. A recent meeting of the "Citizens' Alliance" of Idaho Springs has fully endorsed the action of the "Citizens' Protective League" in driving out the union miners who are accused of having been implicated in the destruction of the mining plant of the Sun and Moon Mining Company. The men composing the Alliance are the leading merchants and citizens of that town, as well as mining operators and owners, and they have thus plainly evidenced their disapproval of any act of violence on the part of the striking Miners' Union in its attempt to gain a desired point in its strike. While it is unlikely that were a vote to be taken by any miners' union on a proposition to injure any mine officer, or to destroy any mine plant, such action would be favored by the union men, yet they are collectively held morally responsible for the independent acts of the lawless members of their organization, and if they care for and desire to win the sympathy and moral support of the community in which they live, they must watch vigilantly to prevent any such demonstration as that at Idaho Springs, for such acts are obnoxious not only to the fair-minded people of the section where these atrocities are committed, but to the entire civilized world.

THE attempts made by novices to write mining reports are often amusing. In a report recently issued for a gold mine, the writer artlessly informs stockholders, actual and prospective—particularly the latter—that forty-five tons are being crushed daily, and the mill is described as having one automatic feeder, with two rock breakers. In another paragraph is the statement that a platform is being built, covered with 2-inch plank, on which it is intended to set the hoist and the two rock breakers. These, and similarly absurd statements, clearly show that the management and direction of the business of the mine is in the hands of inexperienced men.

Mine Sampling.

On page 80 of the issue of July 18 of a New York contemporary appears a communication on the subject of mine sampling from an engineer, resident in Washington, D. C., in which occurs the following:

"The valuation of a block of ore being based on assay results, it is well to consider how these results should be used. The common method is to multiply each assay value by the width of ore at the point where the sample was taken, adding up the resulting "foot dollars" and striking an average to be used with the tonnage of each block to give the total value. In still more accurate work two assays are made of each sample, and these are averaged. Another way, and one which has given very reliable results, is to average the values of two adjacent samples and multiply the result of the average of the two widths of the vein; the product is to be used as the value of that particular part of the ore block; the result is quite different from that obtained by the first method, as will be seen below:

Width.....	2	(6)	10	(6.5)	3	(2)	1	(5.5)	10
Value.....	$20	($11)	$2	($10)	$18	($14)	10	($20)	$30

The average is $85, using the first method, and $67.25 using the last."

An analysis of the above shows serious mistakes in statements and deductions. The so-called "averages" are not averages at all. Then, too, it would be a mathematical impossibility to find an average value of $85, or of $67.25, when the highest ore value in the samples taken was but $30. The method of averaging two adjoining values and dividing by the average of two adjoining widths does not produce the same result as when they are taken separately—note figures above in parenthesis. This discrepancy is pointed out by the author of the Washington article, yet it is referred to in his article as "another way, and one which has given reliable results," which is absurd.

It will be observed that the samples given in the article referred to have been averaged by multiplying the several values by their respective widths, and then dividing by the number of samples taken instead of the total number of feet sampled, which accounts for the very high "average."

If mines were sold on samples taken and averaged in this manner, it would not be surprising to find such a mine fall short of the anticipations of the buyers in the mill run, or by smelter returns.

Seldom does this journal notice such things, for we are ordinarily too busily engaged in a more or less successful effort to keep errors out of our own columns to devote any time to the mistakes of others, but when a case so ridiculously misleading as the one above cited comes to notice, it seems necessary to call attention to so flagrant an error, though it is scarcely likely that practical men would fall into a similarly foolish assumption. Common sense is an attribute that the practical miner is supposed to have, but it is equally essential in other walks of life.

It may be appropriate to append a few suggestions on mine sampling and averaging of values.

No branch of the work of the mining engineer requires more careful consideration, painstaking labor and systematic application of method than the sampling of a mine. The man to whose lot the investigation of a mine may fall owes much to his employer, and a great deal to himself, and he cannot afford to take anything "for granted;" but he must prove everything, and prove it beyond a doubt. Whether his commission is to examine for buyer or seller, the proposition is essentially the same. His business is to investigate for facts, and, having secured the facts, to present them to his client in a form devoid of confusing terms—destitute of mathematical jugglery and free from a "system of averages" which do not average. Moreover, the truth—the whole truth—must be told, not partially, but wholly. If good ore exists, the engineer should so state, giving its value, location and amount, as far as is rationally possible to measure and estimate. If there be poor ore, it should be treated with equal fairness. Nothing which has any bearing on the economic operation of the mine should be omitted from the report.

Mines are of such various character that it is impossible to sample all mines in the same manner. The ideal mine to sample by hand is that one which has a vein of moderate width, where the values are distributed with approximate evenness, the ore neither so soft as to crumble nor so hard as to fly like flint under a blow from the hammer; where channels of even depth and width may be cut with a pick, and where all exposed faces are within easy reach. Such is the ideal, but they are rare. The various conditions met in underground workings must be dealt with according to their kind. It is never safe to assume that an old exposure fairly represents the ore immediately back of it, for in a dry mine the exposed face is usually covered with dust, and in a wet one mud is usually plastered all over the back and sides of drifts or other workings, in depth from a film to a half inch or more. This must affect the sample to a greater or less extent, dependent somewhat upon its relation to the size of the sample. In any case the face should be cleaned, either by cutting a preliminary channel or by blasting off the exposure by a series of "pop shots." It is not often necessary to "pop shoot" a face for samples, but a clean face may be obtained in this manner.

A canvas of liberal dimensions is indispensable in hand mine sampling, as it catches all of the sample, if properly placed. When the ore is wet and sticky as it falls upon the canvas, all of the ore broken down for a sample should be placed in a sack and taken outside the mine for reducing the pieces to smaller size and "quartering down." After transferring the sample from the canvas to the sack the canvas should be cleaned as thoroughly as possible by vigorously shaking, or, if necessary, by turning a stream of water upon it. Several sheets of canvas may be necessary. These cost but a few dollars, very much less than the wine that is an accompaniment of many mining deals. Some engineers provide tin boxes in which to place samples. When a large sum of money is involved in the possible transfer of the property a steel safe would probably be better. As hand samples carefully taken seldom weigh less than five pounds and often fifty pounds each, it is obviously inconvenient to provide suitable metallic boxes for each large sample, but as the several samples are secured, sacked and tied up, they should be placed in the care of a responsible man in the employ of the engineer.

When the samples have been taken and the assays made on them there still remains the responsible task of estimating the value of the "ore in sight," and of the "probable ore" and "possible ore." The meaning and application of these several terms have been so frequently discussed herein before, that it seems unnecessary to say more about them here.

Each sample should be given a number (a running number preferred), to avoid confusion, and each sample number should be accompanied by the width of vein or streak sampled, for without these the work of the sampler is of no practical value. The simplest way to arrive at average and aggregate values is to assume that each foot in width sampled represents one ton of ore, as the ton is the basis or unit of all calculations of cost of mining, transportation and milling. By multiplying the width in feet by the assay value of the sample the product may be assumed to represent the value of as many tons of ore as there were feet sampled at that place. Where several sample values are to be averaged it may be done by multiplying the several widths in feet by their respective assay values, adding these several products together and dividing by the number of feet (tons). The following may be taken as an example:

Number.....	101	102	103	104	105
Width.....	2′	1.5′	6′	3′	4′
Value.....	$10	$20	$5	$12	$8

Assuming that No. 101 represents 2 feet of $10 ore we have 2 tons of $10 ore = $20.

No. 102 represents 1½ feet of $20 ore, or 1½ ton at $20 = $30; No. 103, 6 tons at $5 = $30; No. 104, 3 tons at $12 = $36; No. 105, 4 tons at $8 = $32.

Averaging the above there is found to be a total width sampled of 16.5 feet, representing 16.5 tons of ore containing a total value of $148, or an average of $8.97 per ton.

CONCENTRATES.

WHERE corundum is found mixed with impurities, the mineral may be separated from its gangue and accompanying minerals by careful concentration.

CALORIE is the name given the unit of heat measurement. In chemistry the heat unit is the quantity of heat required to raise a gram of water from 0° C. (freezing point F.) to 1° C.

THE mineral sample from Borate, San Bernardino county, Cal., is silicate of alumina and magnesia, with some sodium chloride; no niter or borax. The rock is essentially clay, with a little common salt.

A "GLORY HOLE" is the name given by miners to an open cut where the ore broken passes downward through an upraise to workings below, and from there sent out of the mine either through a tunnel or shaft.

CALIFORNIA MINES are almost entirely at an altitude of less than 7000 feet; Colorado mines are almost entirely above that altitude, mostly between 9000 and 12,000 feet. The Mt. Lincoln mine, Colorado, is over 14,000 feet above the sea.

AS many machine drills may be employed in sinking a shaft as can be conveniently used, but in three-compartment shafts of liberal dimensions not more than four machines can be used to advantage—two bars carrying two machines each.

THE term agglomerate is employed to designate volcanic breccia, as distinguished from other breccias, and from conglomerates, the latter being made up of water worn fragments, while the former (breccias) are composed of angular fragments.

"HALOGEN" is a chemical term. Fluorine, bromine, chlorine and iodine are known as the halogens, or salt producers, as they each form with metals compounds analogous to sea salt (sodium chloride). Each of them unites with hydrogen to form strong acids.

ALL old tailings dumps should be screened before attempting their treatment by cyanide or any other process, as by this means all lumps may be broken up and all foreign materials removed, such as sticks, rocks, roots, leaves, etc., which would have a tendency to clog pipes and valves.

AMPHIBOLE is a general term for rocks of the hornblende type. It is often used as a prefix, as amphibole-gneiss, amphibole-gabbro, etc. Amphibolite-schist refers more particularly to those rocks in which the hornblende (or augite) has been mostly or entirely altered to chloritic scales and fibers.

MANY devices have been tried to take the place of cams of the ordinary type for the purpose of lifting mill stamps. These comprise a variety of ideas—levers, cogs, etc.; but as yet none of these has outlived the period of test, except the direct steam stamp. Possibly some device superior to the cam may be discovered, but it has not yet made its appearance.

ARSENIC occurs in the free state in abundance in some localities, but it is more commonly combined with other substances, as sulphur, iron, etc. Native arsenic has a grayish-white metallic luster, density or gravity of 5.7, is crystalline and very brittle; volatilizes when heated without previous fusion, but is fusible at a dull red heat, under pressure in a sealed tube.

THE cause of the markings resembling the appearance of galvanized iron noticed on the surface of platinum after it has been long exposed to a high temperature is ascribed by some to the action of the carbon from the flame, and by others to the action of acetylene. Experiments go far toward confirming the idea that such changed appearance is due to recrystallization of the metal.

THE principal objection to scale of ordinary thickness is that it may cause the metal of the boiler to become so highly heated that there is danger of bulging or burning or leakage about the joints and tube ends, with resultant corrosion. As to efficiency it seems likely that soot on the fire surfaces may often be more hurtful than scale of ordinary thickness. Soot is a good non-conductor, and because of this it is often used for clothing steam pipes.

THE statute prohibiting contracts in restraint of trade does not refer to that kind of a restraint of interstate commerce which may arise, from reasonable and legal conditions imposed upon the license of a patent by the owner thereof; since a patent is a monopoly recognized by the Constitution, and the owner of a patent has the right to sell it or to keep it, to license others to sell or manufacture it, and he is not bound to use his discovery himself nor to permit others to use it.

IN the Centigrade thermometer 0° is the freezing point, and 100° Centigrade is the boiling point of water, at the sea level. In the Fahrenheit thermometer 32° above 0° is the freezing temperature of water at sea level and 212° above 0° is the boiling point of water. To reduce Centigrade reading to Fahrenheit, divide the Centigrade reading by 5, multiply the quotient by 9, and add 32. Thus 40° Centigrade = $40 \div 5 \times 9 + 32 = 104°$ Fahrenheit.

FOR a fire test of oil, the oil is placed in a small iron dish, with a thermometer bulb immersed in it, and held in an upright position. The heat is applied under the dish by means of a Bunsen burner, until it reaches the point at which the operator expects it to vaporize. Then a lighted taper is passed around the edge of the bowl, and if the vapor that rises from the heated oil flashes, the temperature recorded on the thermometer is the flash point. One can continue to apply the heat until the oil takes fire and then note the temperature again. This is the fire test.

FOUR plumb lines are necessary in lining up a vertical shaft. Two center lines cannot be depended upon to give correct results. The sets may be true at the centers, but "swing in or out" at the ends. It is a good plan to make a shallow cut with a saw in each wall plate at a stated distance from the inside corner or from some other place, and swing the lines from these points, bringing each set below exactly to the line. Where lines are hung directly from the corners, they are likely to touch, and, not swinging freely, lead to incorrect results, which must later be corrected, with loss of time, which means expense.

ELECTRICALLY driven air compressors are employed to run not only machine drills, but also hoisting engines, pumps above and under ground, and to operate other machines. It has been suggested that compressed air may be reheated underground by the use of steam. A small, well covered steam pipe has been found efficient for this purpose. The steam pipe is carried through the reheating receiver by a series of return pipes. As the steam pipe is small, no inconvenience by reason of increased heat in the mine results, while the air can be heated to within a few degrees of the temperature of the steam. The steam may be exhausted into a sump.

THE pipes in the water circulating system of gasoline engines used on automobiles often clog up and refuse to work. This is often caused by using water containing vegetable matter, which deposits a slime. The pipes may be cleared by filling the tank with a strong, hot solution of either Babbitt's potash or common soda. Run the engine for a few minutes to allow the solution to do its work, then draw off the solution and refill with water. Again run the engine until the water becomes hot and then draw off. This should be done every month to keep the pipes clean under the conditions stated.

THE noise caused by the telephone wire fastened to the building can be prevented by the use of a damper. This may be made as a rubber cylinder about 4 inches long, ½ inch diameter and split lengthwise. It is to be placed on the conductor and bound spirally with fine wire to keep it in place. The rubber damper containing the conductor can be placed upon an insulator, or the wire can be tied in the usual way to the insulator, and the damper may be attached by a wire around it to a damper on a neighboring conductor, or to the fixture, chimney or pole. The idea is to prevent the mechanical communication of the vibration of the conductor to the building.

URANINITE, or pitch blende ($U_3 O_8$), is one of the principal sources of uranium, the other being carnotite. It is grayish, greenish, brownish, velvet black; streak brownish black, grayish, olive green, somewhat shiny. It is usually massive and botryoidal in form, but also occurs in grains. The structure is sometimes columnar or curved lamellar; brittle; hardness 5.5; gravity 9 to 9.7 in the crystals, but 6.4 and upwards in the earthy varieties; soluble in nitric and sulphuric acids, though the solubility differs in different varieties, being greater in those kinds containing the rare earths; non-magnetic. It occurs as a primary constituent of some granites, or in veins associated with ores of silver, lead, copper, etc.

THE large production of zinc has grown up in the United States within the past twenty years. In the earlier days of the lead mines of Missouri zinc was an unwelcome mineral. It interfered with the disposal of the lead ores when the two were mixed, and the galena had to be sorted out clean. Even the clear zinc ores were unsalable in the United States, as there were few furnaces in this country where zinc ores could be treated. The zinc ores produced in those days were stacked up on the dumps. It was not worth much over $10 per ton. The Joplin district, in southwest Missouri, is the largest producer of zinc in the United States at present. Colorado is also outputting a large amount of zinc ore, particularly since the advent of the electro-magnetic separator.

THE cost of open-cut work at mines varies greatly in different localities, and may have a wide range in the same mine, depending upon many factors. The essentials for cheap mining by open cuts are large masses of clean ore, not too hard, but not dangerously soft and having a tendency to cave; mill holes in the lower portion of the cut through which the broken rock passes away by gravity; good judgment, born of experience in placing and charging drill holes; experienced and energetic workmen, and good weather. With these mining should be cheaply done. Some open-cut work is expensive for the reason that all the rock broken is shovelled into cars. This is often necessary in beginning operations in a cut, but it does not pay to shovel rock that will run to a chute by gravity; to this end a chute must first be provided.

WHEN water is boiled under a pressure of five atmospheres, or seventy-five pounds pressure, the sensible heat is 306° F., the boiling point at that pressure; but the latent heat has decreased by the same number of heat units that the boiling point increased, so the total is the same in all cases. In the first case we have 212° minus 32° plus 966°, or 1146°, and in the second case, 306° minus 32° plus 872° equal the same, 1146 heat units. In evaporating a pound of water under atmospheric pressure, the temperature remained at 212°, but the volume was increased to 1644 times that of the water in the second case; evaporating under seventy-five pounds pressure, the temperature also remained the same—306° F.—but the volume is only 295 times that of the water it was evaporated from. This is one of the reasons it pays to run an automatic cut-off engine.

A MINER who desires to take a contract to sink a shaft may give a bond to accomplish the work at a stated price within a specified time, but such proceeding is unusual and is rarely required by the owner. A mechanic or architect can figure upon the construction of a building, as the amount of materials necessary is easily and arbitrarily arrived at, and the amount of labor requisite may also be estimated with comparative exactitude, for in such work the conditions are practically constant; but in shaft sinking conditions change or may change with each foot in depth. Rock changes from hard to soft, or vice versa. Water comes in unexpectedly; blasts smash timbers, which must be replaced, and numerous unforeseen contingencies are constantly arising, which makes the giving of a bond for the performance of the work at stated price and within a given time an unbusinesslike proposition. The owner usually finds his safety in withholding a percentage of the price as the work advances until the contract is completed, and this has generally proven satisfactory to all concerned.

IN the case of Gartney vs. Gosling, the Supreme Court of Wyoming, 68 Pac. Rep., 1118, held that a "mining partnership can exist only where several parties cooperate in working the mining property, mere ownership as tenants in common not being sufficient. In a mining partnership pure and simple one partner has no implied authority to borrow money on the credit of the firm, but his implied powers only permit him to bind his co-partners by dealings on credit for the purpose of working the mine, where it appears to be necessary or usual in the management of the business. An agreement where certain parties furnish one of their number with a fixed amount of money, he to go to Alaska and prospect for a mine, and they during his absence to furnish his family with a stipulated monthly allowance for its maintenance, each of the parties to have a certain prescribed interest in whatever was found, could not be construed as binding the others for expenses incurred by the prospecting party for personal supplies after, or even before, the sum originally furnished had been exhausted. But, where a mining contract did not make parties to same liable for supplies furnished one of their number, yet a letter written to him by one of their number authorizing him to buy the supplies, could not have the effect to bind the other parties in the absence of evidence that they knew of or authorized its being written. Such letter would be admissible against the one who wrote it as to supplies bought from a party after such party had seen it, but not supplies bought before it was written."

PALLADIUM is usually found associated with the rare metals rhodium, osmium, ruthenium and iridium. It occurs usually associated with gold and has been found in the placer mines of the Cariboo district, B. C. Some gold ores of Brazil contain from 5% to 10% of metallic palladium, which is obtained by fusing it together with silver and dissolving the granular alloy thus obtained in hot nitric acid, when the gold only remains. By addition of a solution of sodium chloride, the silver is precipitated as chloride, which is removed by filtration. The palladium in the solution is then precipitated by means of mercury cyanide in the form of a yellowish-white, gelatinous substance—palladinous cyanide. This, on heating to fusion, becomes a spongy, metallic palladium. Palladium has the lowest melting point of any of the platinum group of minerals—about 1500° C. It resembles platinum in color and luster and steel in hardness. It is more malleable than platinum and is more readily welded. When polished, it has a steel-like whitish luster and does not tarnish. Tincture of iodine will blacken the surface of palladium, but not of platinum. The metal, on account of its resistance to oxidation under ordinary atmospheric conditions, is used in the manufacture of chronometers and fine watches and also to some extent in the construction of balance beams of fine assay scales. Palladium may be detected, when present, by mixing a solution of sodium thiosulphate with a small amount of ammonia and adding a drop of the solution of the ore supposed to contain palladium, so as to color the liquid pale lemon yellow. Boil and watch for changes in color from wine-brown to black. Diluted with water, it returns to the former color but remains clear.

Desulphurizing Slimes by Heap Roasting.*

Written by E. J. HORWOOD.

It is well known that owing to the intimate mixture of the constituents of our sulphide ore at Broken Hill, New South Wales, a great deal of crushing and grinding is required to detach the particles of galena from the zincblende and gangue of the ore, and in this operation a considerable amount of the material is converted into a slime which consists of minute, but well defined particles of all the constituents of the ore and combinations thereof, the relative proportions of which depend on the dual characteristics of hardness and abundance of the different constituents. An analysis of the slime shows the contents to be as follows:

Galena (PbS)	24.00
Blende (Zn S)	29.40
Pyrites ($Fe S_2$)	3.38
Ferric oxide ($Fe_2 O_3$)	4.17
Ferrous oxide (Fe O) contained in garnets	1.03
Oxide of manganese (Mn O) contained in rhodonite and garnets	6.66
Alumina ($Al_2 O_3$) contained in kaolin and garnets.	5.40
Lime (CaO) contained in garnets, etc	3.40
Silica ($Si O_2$)	22.98
Silver (Ag)	.06
	100.48

Galena, being the softest of these, is found to a arger extent in the slime than in the crude ore; it is also, for the same reason, in the finest state of subdivision, which latter condition is well illustrated by the fact that the last slime to settle in water is invariably much the richer in lead, while the percentages of the harder constituents, zincblende and gangue, show a corresponding reduction in quantity, by reason of their being generally in larger sized particles and consequently settling earlier.

The fairly complete liberation of each of the constituent minerals of the ore that takes place in sliming tends, of course, to help the production of a high-grade concentrate by the use of tables and vanners, and undoubtedly a fair recovery of lead is possible, even with existing machines, in the treatment of fine slimes; but, owing to the great reduction in the capacity of the machines, which takes place when it is attempted to carry the vanning of the finer slimes too far, and the consequently greatly increased area of the machines that would be necessary, the operation, sooner or later, becomes unprofitable.

The extent to which the vanner treatment of slimes should be carried is, of course, less in the case of those mines owning smelters than with those which have to depend on the sale of concentrates as their sole source of profit. In the case of the Proprietary Co., all slime produced in crushing is passed over the machines after due classification. A high recovery of lead in the form of concentrates is neither expected nor obtained, for reasons already explained; but the finest lead-bearing slimes are allowed to unite with the tailings, which are collected from groups of machines, and are then run into pointed boxes, where, with the aid of hydraulic classification, the fine rich slimes are washed out and carried to settling bins and tanks, where the water is stilled and allowed to deposit its slime, and pass over a wide overflow as clear water. The slime thus recovered amounts to over 1200 tons weekly, or about 11%, by weight, of the ore, and assays about 20% lead, 17% zinc and eighteen ounces silver, and represents, in lead value, about 11% of the original lead contents of the crude ore and rather more than that percentage in silver contents. These slimes are thus a by-product of the mills, and their production is unavoidable; but as they are not chargeable with the cost of milling, they are an asset of considerable value, more especially so since it has been demonstrated that they can be desulphurized sufficiently for smelting purposes by a simple operation, and, at the same time, converted into such a physical condition as renders the material well suited for smelting, owing to its ability to resist pressure in the furnaces and to its lumpy nature.

Proceeding now to the operations more closely connected with the subject of this paper, it is necessary to mention that the company has many thousands of tons of this material which the smelters have hitherto been unable to cope with, owing to the roasters being fully occupied with the more valuable concentrates. Moreover, the desulphurization of this class of material in mechanical roasters is objectionable for various reasons, namely, owing to the large amount of dust created with such fine material, resulting injuriously to the men employed, also on account of the reduction in the capacity of the roasters, and consequently increased working cost which accompanies the operation, owing to the lightness of the slime, especially when hot, as compared with concentrates, and the necessity of limiting the thickness of material on the bed of the roasters to a certain small maximum depth. Further, the desulphurization of the slimes is no more complete with the mechanical roasters than in the case of heap roasting, and the combined cost of mechanical roasting and briquetting being 3 shillings per ton in excess of the cost of heap roasting, this method possesses many advantages. These heaps are being dealt with, preparatory to roasting, by picking down the material in lumps of about 5 inches in thickness—a suitable size for heap roasting—while the fine dry smalls, unavoidably produced, are worked up in a pug mill with water, and dealt with in the same way as the wet slime produced from current work, and handled as follows:

The slime, as produced at the mills, is run from bins into railway trucks in a semi-fluid condition, and shortly after being tipped alongside one of the various sidings on the mine, is in a fit condition to be cut with shovels into rough bricks, which dry fairly quickly, and when required for roasting are easily reloaded into railway trucks. As each man can cut about twenty tons of brick per day, the cost is small. Various other methods of lumping the slime were tried, including trucking the semi-fluid material on movable trams, alongside which were set laths, about 9 inches apart, which enabled long slabs to be formed 9 inches wide and 5 inches thick, which were, after drying, picked up in suitable lumps and loaded on platform trucks, thence on railway trucks. Owing to the inferior roasting that takes place with bricks having flat sides, which are very liable to come into close contact in roasting, and to the high labor cost, this method was discontinued. Another method was to allow the slime to partially dry after being emptied from railway trucks, and to break it into lumps by means of picks; but this method entailed an increased amount of smalls being made, besides taking up more siding room, owing to the extra time required for drying, as compared with the method now in use. Ordinary bricking machines could of course be used, but when the cost of handling the slime before and after bricking is counted, the cost would be greater than with the simple method now in use; the material being in too fluid a condition for making into bricks until some time elapses for drying, a double handling would be necessitated before sending to bricking machine. If, however, the slime could be allowed time to dry sufficiently in the trucks, bricking by machinery would probably be preferable. Rather more than 10% of smalls is made in handling the lumps in and out of the railway trucks, and this is, as before mentioned, worked up with water in a pug mill at the sintering works, and used partly for covering the heaps with slime to exclude an excessive amount of air. The balance is thrown out and cut into bricks as already described.

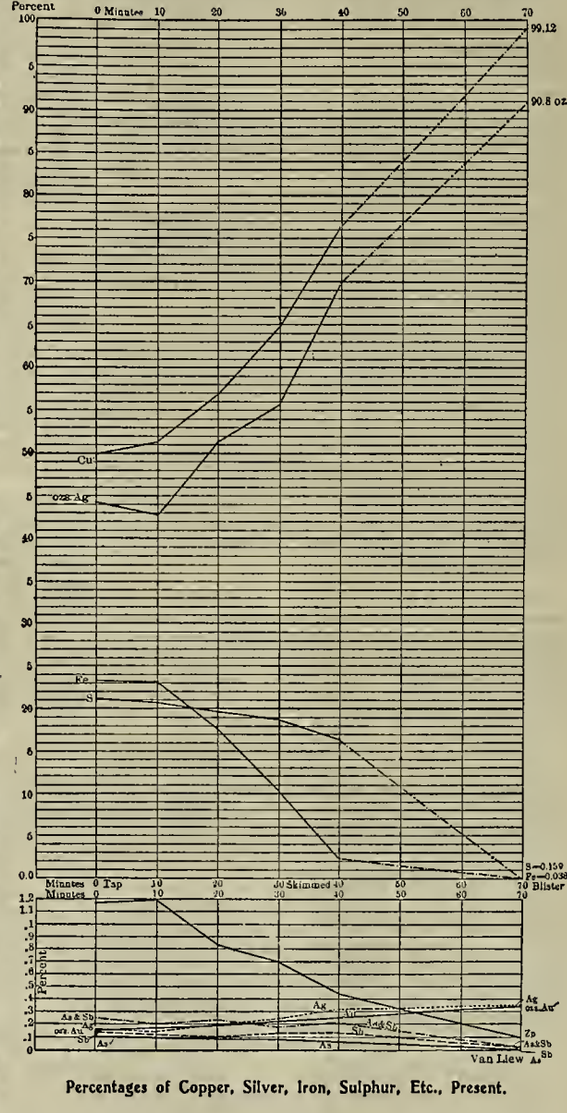
At the heaps, the lumps are at present being thrown from one man to another to reach their destination in the heap, but the sidings have been laid out in duplicate with a view to enabling traveling cranes to be used on the line next the heap, the lumps to be loaded primarily into wooden skips fitting the trucks. It is probable, however, that the lumps will require to be handled out of the skips into their place in the heap, as the brittle nature of the material may be found to render automatic tipping impracticable. A considerable amount of labor would nevertheless accompany the use of cranes, which would likewise be advantageous in loading the sintered material.

In order to reduce the inconvenience arising from fumes, length is very desirable in siding accommodation, so that heap bullding may be carried on at a sufficient distance from the burning kilns. It is for the same reason preferable to build in a large tonnage at one time, lighting the heaps altogether. As the heaps burn about two weeks only, long intervals intervene, during which the fumes are absent.

In the experimental stages of slime roasting, fuel, chiefly wood, was used in quantities up to 5%, and was placed on the ground at the bottom of the heap, where also a number of flues, loosely built of bricks, were placed for the circulation of air. The amount of fuel used has, however, been gradually reduced, until the present practice of placing no fuel whatever in the bottom was arrived at; but instead, less than 1% of wood is now burned in small enlargements of the flues, under the outer portion of the pile, and placed about 12 feet apart at the centers. This is found to be sufficient to start the roasting operation within twenty-four hours of lighting, after which no further fuel is necessary.

(TO BE CONTINUED.

*Abstract Trans. Australian Inst. Min. Engrs.



Submarine Ore Mines.

A legal difficulty is approaching on the Mesaba and Vermillion iron ranges, with the State of Minnesota and its lessees on one side and the fee owners of the land around the lakes on the other, says the American Manufacturer. It has been acknowledged as a principle of common law that the riparian ownership of meandered lakes carried with it any rights of the ownership of land under water that could be held for private use, other than the inalienable rights of the public. Acting on this idea, no land under water has ever been leased for mining purposes except by the owners of adjoining lands. But now comes the State Auditor and gives to private applicants mineral leases upon lands under water that are entirely surrounded by fees held by individuals and companies. The State, in other words, claims, by virtue of the Swamp Act, to be owner of all lands under water, up to the shore line, and as such is to dispose of those tracts for any purpose. It may be that millions of value lie in these lands. Some of them are well located on both ore-bearing formations. One lease has already been granted and applications are in for thirty more. Fee owners will contest the leases and will treat anyone who crosses their lands to explore under these lakes as trespassers, so that it will be very difficult, in many cases, to reach the lakes. If the State owns these lands, the royalty is a part of the school and institution funds.

Relative Elimination of Impurities in Bessemerizing Copper Matte.

Written by W. RANDOLPH VAN LIEW.

In determining the relative rate and in finding the point where different impurities contained in copper matte are eliminated during the process of a converter blow, the following results were obtained:

Percentages of Copper, Silver, Iron, Sulphur, Etc., Present.

A converter was selected which was starting on its second charge. The first charge after lining had finished its copper "hot," and consequently no copper was adhering to the sides of the lining. All the copper and granulated slag from the previous charge were dumped, thus removing any possibility of "salting" the matte to be tested.

The converter worked fast and well during the entire test. Periods of ten minutes were selected. The converter was brought from the stack to secure each sample of matte to be analyzed, and only that time counted during which air was being forced through the charge.

At the end of forty minutes' actual blowing the matte was up to "white metal," the point at which the last skimming takes place—that is, matte of ap-

* Trans. Am. Inst. Min. Engs.

proximately 76.4% copper. From here, of course, average samples of the contents of a converter are impossible, since (from this skimming point up to finished copper) the contents of a converter consist of constantly varying proportions of matte and copper, which, when a converter is brought from the stack and the blast pressure turned off, settle according to their specific gravity. When the charge is completed a granulated sample of finished copper is obtained and assayed. Accurate chemical analyses of these equal-period samples of matte and copper gave the following results:

	Cupola Tap.....	10 Minutes.....	20 Minutes.....	30 Minutes.....	40 Minutes Last Skim.....	70 Minutes Blister Copper...
Copper, %.....	49.72	50.20	56.88	64.60	76.37	99.120
Iron, %.....	23.31	23.15	17.85	10.50	2.40	0.038
Sulphur, %....	21.28	20.95	19.74	18.83	16.30	0.159
Zinc, %.....	1.19	1.20	0.84	0.70	0.45	0.090
Arsenic, %....	0.11	0.09	0.08	0.08	0.08	0.0012
Antimony, %..	0.14	0.12	0.10	0.13	0.13	0.006
Silver, oz	44.20	42.90	51.40	55.80	70.00	90.800
Gold, oz.....	0.16	0.14	0.20	0.24	0.32	0.350

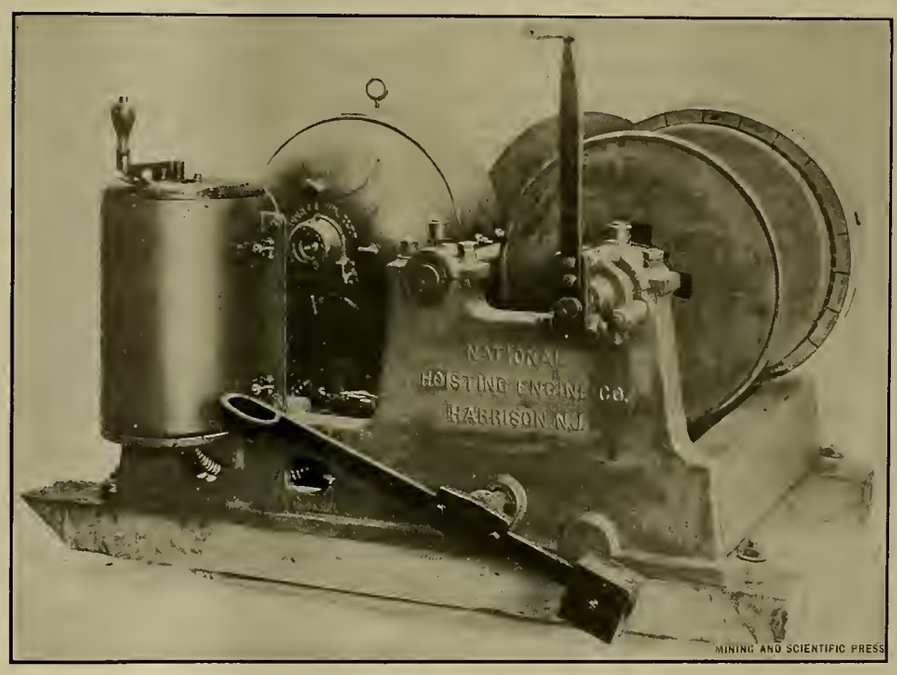
The accompanying figure illustrates graphically the history of their elimination. In this figure the abscissa represents the ten-minute periods of blowing, and the ordinates represent percentages of copper, etc., from 0 to 100. The ordinates of the figure at the bottom are the same, but on a larger scale (from 0 to 1.2%), to show better the impurities in the matte carried to the extent of but a few tenths of 1%. The upper diagram shows that the silver almost parallels the enrichment of the matte in copper.

The lines showing the relative elimination of the iron and the sulphur are the most interesting. For the first ten minutes of the blow, and while the matte is heating up, the iron and sulphur lines are parallel. From this point there is a marked change. The sulphur line is very gradual in its drop, showing that but little is being burned in comparison with what is taking place with the iron, whose line takes a sudden drop. The iron decreases during thirty minutes from 23.15% to 2.4% at the skimming point, while at this point there still remains 16.3% of sulphur in the matte. From this point, however, to blister copper it is the sulphur that bears the brunt of elimination, the iron dropping only from 2.4% to 0.0038% at blister copper, while the sulphur decreases from 16.3% to 0.15%.

This is of great interest, as it shows that, up to the skimming point, it is the oxidation of the iron to ferrous oxide, and the union of the ferrous oxide with the silica of the lining, that affords the source of heat to carry on the operations within a converter; while from the skimming point (76.4% copper) to the finished blister copper it is chiefly the burning of the sulphur that gives our heat supply to finish the work started by the oxidation of iron.

The zinc, it will be seen, is scarcely affected during the "heating up" period, while after that its elimination is gradual. The arsenic and antimony, curiously enough, are but slightly affected during the whole of the slag-forming period, or as long as enough iron remains to be slagged off. At the cupola tap of matte into the converter the arsenic was 0.11% and the antimony 0.14%, while at the end of the slag-forming period the arsenic was 0.08% and the antimony 0.13%.

When the iron in the matte had been oxidized and slagged off, and then only, did the arsenic and antimony commence to be oxidized and driven off, until, at the point of blister copper, but 0.0012% of arsenic and 0.006% of antimony remained.



Iron and Steel Imports.

Importations of iron and steel into the United States in the fiscal year 1903 are larger than in any preceding year since 1891, and with that single exception are larger than at any time within the past twenty years. In only seven earlier years in the history of the country have the importations of iron and steel been as large as those of the fiscal year just ended. The total value of iron and steel imported in the fiscal year ended June 30, 1903, as shown by the figures of the Department of Commerce and Labor through its bureau of statistics is $51,617,312, against $27,180,247 in 1902, $17,874,789 in 1901, and $12,100,440 in 1899. Running back through the import record from 1850 down to 1903, the only years in which the value of iron and steel imports exceeded those of 1903 are 1872, when the total was $55,540,188; 1873, $59,308,452; 1880, $53,714,008; 1881, $60,604,477; 1882, $67,976,897; 1883, $58,495,246; and 1891, $53,544,272. These large importations of iron and steel have occurred, it will be seen, in periods of exceptional business activity, but on no former occasion have such large importations been made in the face of so great home productions of iron and steel. In 1891, when the importations were $2,000,000 greater than in the year just ended, the total home production of pig iron was only 8,500,000 tons, while that of 1902 was over 17,000,000 tons, or double that of 1891. In the period from 1880 to 1883, when the importations of iron and steel were larger than those of 1903, pig iron production only averaged about 4,000,000 tons per annum, or less than one-fourth the annual production of the present time; and in 1872 and 1873, when the importations slightly exceeded those of 1903, the pig iron production averaged only 2,500,000 tons annually, against 17,000,000 at the present time.

A Motor-Driven Mine Hoist.

The motor-driven friction-drum hoist illustrated herewith has been built to meet the demand for a small, compact, portable and, as nearly as possible, indestructible machine for use in mines, quarries, on board ships, and for contractors' purposes generally. It is manufactured by the National Hoisting Engine Co. of Harrison, N. J., and is equipped with a Crocker-Wheeler fully inclosed type series motor, which drives the drum through two trains of reducing gears. The portability of the outfit is indicated by the cut, which shows the motor, controller, drum, etc., all supported upon the one cast iron base. The motor is the 7½ H. P. size, wound for 220 volts and drawing normally, at full load, a current of 30 amperes. The controller, which is of Cutler-Hammer make, designed for intermittent regulating duty, is of the size to accompany a 7½ H. P. motor, and allows twelve speeds in either direction.

At maximum speed and power the hoist is capable of lifting 1500 pounds at the rate of 125 feet per minute with the motor running at 800 revolutions per minute. The position of the operator is at the side of the machine, shown in the picture, where, with his left hand on the controller, he can govern the speed of rotation of the drum in either direction, or, with his right hand on the chuck release, may disconnect the drum from the gears and allow it to rotate under the weight of its load while checking the speed by applying the friction hand brake with his foot.

A Motor-Driven Electric Hoist.

The equipment throughout is designed to withstand the rough usage and exposure that it must naturally be expected to receive. The resistance used in connection with the controller is of the Carpenter enclosed form and mounted in a safe position under the base of the frame. The leads between the controller, motor and resistance are run in flexible metallic conduit, all delicate parts liable to disarrangement are carefully enclosed and protected from dust, moisture and results of careless handling.

The company has a branch office in San Francisco, Cal., corner Fremont and Howard streets.

GOLD POCKETS occur under many conditions—in black slate, in talc, in diabase, at contacts, in limestone and in diorite, but usually where two or more veins or seams converge. There are usually three separate fissures, crevices or veins. First is the vein of quartz proper. This is usually barren except where the pockets occur. Next is the crossing—a seam or small vein or crack—cutting across the vein and third the gold seam, the latter being important. It strikes nearly parallel with the vein and dips toward it. Where these three unite the pocket of gold may or may not be found. The occurrence of pockets is very uncertain under any circumstances; and, although the searching for pockets has been reduced to almost a science, the element of luck is an important factor.

Some Observations on Alaska and the Northwest Territory.

Written for the MINING AND SCIENTIFIC PRESS by W. E. THORNE.

Along Forty-mile river the surface rocks are principally sedimentary overlying granite. These sedimentary beds dip at all angles up to 80° from the horizontal. In some places the anticlinal folds have been cut through by erosion, leaving granite bedrock. The greater portion of the bedrock is clay slates, limestone and schist. The strike of the formation is about north 15° west. A great deal of the formation is identical with that of California.

In some places dikes cut through the sedimentary formations. Usually along such dikes can be seen quartz veins, some showing pyrite and said to carry gold in small quantities. I saw some telluride ores, but made no test as to values. In the schists and slates numerous quartz stringers occur; in some places a number of these lie parallel, making a fair showing, but no work has been done on them. I saw some quartz from Chicken creek that was rich in free gold.

About the same conditions are found along the Yukon in so far as one could judge from the deck of a steamboat with a good field glass. I found by testing that a lot of the reported rich placer gravel was too poor to work even in so favored a locality as California.

High working cost is due to excessive cost of supplies, short season, frozen ground (in one 55-foot shaft it was found frozen all the way down) which never thaws out during the summer season. In fact, you can find frozen ground at a few inches in depth on the north hillsides all season. High wages make these gravels of no value as an investment, as there is no method in use to-day that would make them pay even operating expenses. The high wages of that country are of little benefit to the miner, as four months is the working season. What he makes will pay for his provisions and clothing. As a rule, they spend the balance of the year prospecting and are broke at the end of the year. As for the chance of making a strike, it is just as good in the United States, with nothing like the privations there. The newspapers of that country, as a rule, publish every fake story that they hear of reported strikes, fully 75% of those reported having no foundation except some "hot air" miner, and are published to keep up the rush into that country. No failures are ever reported, and there are plenty of them—some on a large scale, too. At least 70% of the population could leave that country and not reduce the output of gold 10%. This is only my opinion, and costs nothing, and can be taken for what it is worth. It comes from a five-months sojourn there out in the hills working, and not in a steam heated room in Dawson. I saw some gravel bars and bench claims that can be made to pay if good dumps can be had and worked on a large scale. I also saw some operations there on a large scale in which 75% of the expenses were charged to "office expense."

I found that, after a gravel bank is opened up, it will thaw from 4 to 16 inches in twenty-four hours, so that in piping one must have a large face to work on, also two giants for each head, with extra pipe, gates, etc., so that while one giant is at work the other can be put in place for the next run.

In some places there is a heavy overburden of muck. In working, the gravel is cut from under the

muck by the giant from 3 to 7 feet, then the muck can be shattered by powder. A light stream should then be turned on, when the muck will soon thaw and float off. This muck is decayed vegetation.

Another way of handling the muck is to remove the timber, brush and moss, then by a system of ground sluicing the muck is removed. I am not prepared to say which is the better method. I found in some places one would work all right, while in another place the other was better. I found that fully 90% of the miners in that country had had no practical experience in mining before going there. As a result, some of the theories as to placer gold formation would stump some of our best geologists. There are also some of the crudest gold-saving appliances I have ever seen in operation. I have never seen in any other part of North America such costly methods of handling material as are in use there. I am sure there is a great deal for one to learn about mining methods in that country, but I also think that practical experience before going in is of some benefit towards future dividends, as what little I have gained in twenty years saved our company a good many thousand dollars.

Small timber for fuel is plentiful for present needs, but for lumber is very scarce; logs that will make 6-inch boards are about the average, and not at all plentiful. The quality is like a second growth fir or spruce—very poor. Some of the trees examined showed from 150 to 200 rings or years of growth not over 10 inches in diameter.

Some coal is being developed which is of a fair steam quality, and in time may be sufficient for all needs, as the coal indications are found over a great deal of that country.

Chlorine Smelting, With Electrolysis.*

Written by JAMES SWINBURNE.

The chlorine process is simplicity itself. The sulphide ore is treated with chlorine so as to displace the sulphur and absorb all the chlorine. The chlorine is electrolyzed to get the metal and recover the chlorine. This is the process in its naked simplicity. When all the details necessary, even in connection with complex ores, are considered, in comparison with existing methods, the process is exceedingly simple.

As a good example, supposing pure galena is to be smelted. The galena is treated with hot chlorine so as to form lead chloride and sulphur. The sulphur is condensed as brimstone and the lead chloride is electrolyzed in the fused state, producing lead and chlorine. If there is silver or gold present the fused chloride of lead is treated with metallic lead. This replaces any gold or silver there may be, and the precious metals alloy with the remaining lead, so that ultimately a bullion is produced as rich as may be desired, the only difference being its smelting point, which must not be too high. The cost of desilverizing by the ordinary process is thus saved. This practice thus recovers all the silver, all the lead and the gold, and nearly all the sulphur. If the electrolyte vats were so tight that no air got in all the sulphur would be saved, but in practice a little sulphur is always burned into SO_2. Pure, or nearly pure, lead sulphide is easy to smelt in the ordinary way, but this smelting does not separate the silver and is thus incomplete. In time, therefore, the chlorine process is likely to replace the present methods, even for pure ores. Take another example—pure zinc sulphide. The process is exactly analogous to that for pure galena. But in practice zinc blende contains gangue and generally iron, and these must be separated. One of the greatest advantages of the chlorine process is that it is applicable to mixed ores, which are often absolutely refractory and useless otherwise. This process makes concentration unnecessary, unless merely for eliminating gangue, as the presence of several metals gives rise to no difficulty. In no case has one metal to be lost in order to extract another, and in no case is a metal brought out impure or needing refining. Take, for example, a mixture of sulphides of lead, zinc and iron, with some silver. An immense amount of work has been done on this class of ore, and great progress has been made in concentrating, so that one part will leave enough zinc to be worked, and little enough lead not to interfere with the metallurgy, and the other part will leave enough lead and little enough zinc. Each portion is smelted for one metal only, the other being worse than wasted, as it is a nuisance. An intermediate ore, often a large proportion, is thrown away.

The new process takes the ore as it comes from the mine, without any previous treatment; or, better still, it takes the slimes, such as the Broken Hill slimes, which are at present accumulating as a monumental memorial to the barbarity of present smelting processes. The slimes contain zinc, lead, iron, silver and gangue. Hot treatment with chlorine converts the whole of the metals into chlorides, producing a broth of mixed fused chlorides and gangue. The silver is extracted by substitution of lead, the lead is extracted by substitution of zinc, and the iron is thrown out as ferric oxide, not as metal, zinc oxide being used as substitute, and the gangue is got out by filtration. We have then nothing left but zinc chloride, and this is electrolyzed to yield zinc and chlorine.

The process thus consists of three essential elements:

Treating the ores with chlorine;

Chemical treatment of the mixed chlorides, by substitution, so that all the chlorine is combined with zinc;

Electrolysis of the zinc chloride to extract the zinc and recover the chlorine.

One of the chief merits of the process is that it is so perfectly cyclical. The chlorine merely goes round and round; the works takes in ore and electrical energy, and turns out metals, sulphur and gangue. In treating sulphide ores with chlorine, as in analysis, or in the action of chlorine on sulphides generally, chloride of the metals and chloride of sulphur are produced. This is the reaction described in most text books of chemistry. The formation of chloride of sulphur would be fatal to the process, however, as we should lose both the chlorine and the sulphur, but there is no convenient way of getting rid of large quantities of this offensive compound, far less of recovering the chlorine and sulphur. Decomposing with water is not a cyclic nor a practical process.

The discovery that sulphide ores can be decomposed on the large scale by chlorine so as to give off sulphur and not its chloride is, if we may say it with modesty, a possible turning point affecting a vast realm of metallurgy. The middle parts of the process, by which the mixed chlorides are converted into chloride of zinc by substitution and elimination of the other metals and of the gangue, involve ordinary chemical engineering only, though there is considerable room for ingenuity in inventing and working out the methods on a large scale. The electrolysis of zinc chloride is supposed to be very difficult or impossible. We have overcome many difficulties. Zinc is chosen as the final metal to be separated from the chlorine for two reasons: Because it is chemically easy to substitute it for all the metals we want to extract, as it is very electropositive; and because it is very easy to extract by electrolysis.

SMELTING LEAD ZINC BLUESTONE.—The actual process, as applied to some particular ore, may now be described. The Broken Hill slimes may be taken as a good example. The crushed ore is run into a transformer. This looks like a small blast furnace made of fireclay with iron outside, or of lined iron. It runs continuously, and we may start our description at the stage when a tapping has just taken place. The transformer then contains about a hundredweight of fused chlorides and gangue. The gangue almost floats in the chlorides. If much lead is present much of the gangue floats, so there is no caking or silting up. The top of the transformer has a cone like a little blast furnace. Ore is poured into the fused chlorides, and at the same time chlorine is blown in. The chlorine enters at the bottom by a sort of tuyere, which is a carbon tube. The cold part of this tube is connected to an iron pipe, which brings the chlorine. Dry cold chlorine is easy to handle. It does not touch metals, and iron can be used freely. The chlorine bubbling through the fused bath displaces the sulphur, which comes off and is condensed. The action of chlorine on the sulphides in question evolves a great deal of heat, so that the transformer is self-heating, and there is no coal or coke firing or outside heat of any sort. The temperature is controlled by the rate of admission of chlorine. If the temperature is too low chloride of sulphur may be formed. This may also be formed if there is a deficiency of ore supply. On the other hand, if the chlorine and ore are supplied too quickly, the transformer will get too hot, and some of the chlorides will distill over and be condensed with the sulphur. By running the transformer fast the temperature can be got so high that all the chlorides distill over, leaving only the gangue. The bulk of the transformer gives easy regulation.

The temperature is the main consideration in determining the size of the transformer. It must be of such a size that when running at its normal rate the heat is conducted through the lining and radiated from the surface at such a rate that the contents keep at the right temperature. There is considerable margin allowable in temperature, and the temperature is under control by regulating the flowing of chlorine and of ore. The temperature can always be lowered by running in a little extra ore or reducing the chlorine; but the chlorine feed depends on the electrolytic vats, and is practically constant. The larger the transformer the longer it will preserve its temperature with any fluctuations of chlorine supply, and the cheaper the pumping, labor, etc. It is therefore best to have large transformers. We have so far used a 10-ton, but a larger size with thinner lining will probably be better.

The amount of gangue in the ore is important. As the gangue is about the same density as the chlorides, a large amount may be present without inconvenience as to fluidity. It is, of course, an advantage to be able to work on ores with little metallic content. It is quite easy to work with the metallic contents only half the ore, or even less. Poorer ores can be made workable by addition of those with more metal. The temperature depends on the metals in the ore too. Thus blende heats much more than copper sulphide; so that, other things being equal, a copper ore with little zinc should be run through faster, or mixed with, say, a zinc-lead ore.

To return to the working of the transformer, it is started with the remains of the last charge, and then chlorine and ore supplied till it is full. The regulation needs no skill. A hole can be opened at the top of the transformer, and as it is connected through the sulphur chamber to a chimney there is a gentle suction. This draws air in the hole, which burns the sulphur vapor. The blue flame shows there is enough ore. If too little is fed, fumes of ferric chloride fill the top of the transformer and pass into the sulphur. This is to be carefully avoided, and there should be excess of sulphides in the transformer until the end of the charge. At the end the ore is stopped, and the transformer run till brown fumes appear. These are by-passed round the sulphur chamber. The charge is then run out and allowed to cool.

At first great difficulty was expected in pumping the chlorine, as a pressure of some ten to fifteen pounds on the inch is needed when the transformer is nearly full. The pumping presents no difficulty, and a chlorine pump will run day and night continuously without trouble. The well-known patented method with sulphuric acid flooded pumps would have been available; but such complications are quite unnecessary with dry chlorine. The dryness is of vital importance here.

We now come to the intermediate or chemical stage of the process. This varies with the ore used. We may take the Broken Hill slimes, and imagine there is copper, too. This would be about as troublesome an ore as we could have. We have used the Broken Hill ore and mixed it with a Tasmanian copper ore, but we have chiefly worked on it alone. The fused mass from the transformer consists of chlorides of lead, zinc, iron, manganese, copper, silver and gangue. It is run into water and through a filter press when cool enough. This takes out the gangue and lead chloride, carrying most of the silver. The gangue is easily separated from the lead and silver chlorides, and these chlorides are then dried and fused in contact with lead which extracts the silver and any gold; and then with zinc, which gives lead, practically pure, and anhydrous neutral zinc chloride, which is ready for the electrolysis vats.

The filtrate from the press contains a little lead and silver in solution, and copper, iron, manganese and zinc. The lead and silver are taken out with spongy copper. The copper is taken out as sponge or "cement" by zinc, and we have left iron, manganese and zinc chlorides.

The iron is chlorinated up to the ferric state, and zinc oxide is added to cause precipitation. This throws down hydrated ferric oxide. This is the base of iron paint, and is marketable, its value depending on the color obtained. The solution is further chlorinized in presence of more zinc oxide, and the manganese goes down as peroxide.

We have now substituted zinc for all the other metals in their chlorides, and have nothing left but zinc chloride. This is evaporated down carefully and fused. This decomposes some of the chloride and makes an oxychloride. Steinhart evaporates in vacuo to produce neutral anhydrous zinc chloride. We have not done this; we find that with cautious boiling down there is not much oxygen in the final result. This is got rid of in open preliminary vats, which use inexpensive anodes, which are gradually used up. The consumption is less than if all the oxygen went off as monoxide. The anhydrous neutral chloride from these vats is then added to that from the lead chloride substitution, and is taken to the final electrolysis vats.

The electrolysis vats are internally heated, as in the case of aluminum. The cathode is fused zinc, and the anode is carbon. Some makes of carbon do not stand well, but suitable carbons serve to stand permanently. Of course chlorine has no action on the carbons. The vats are kept under a very light suction, so that if there are any leaks air goes in instead of chlorine coming out. The carbons are not hot enough to be burnt by this small admission of air. As the vats are kept warm by the excess of the electrical power over the chemical, the larger the cell the lower the electromotive force, so that if the cell were large enough we could get down nearly to the electromotive force corresponding to the heat of formation of zinc chloride at that temperature. So far 3000 amperes has been the current used, but this means a very small vat. The output of fused salt vats is enormous in comparison with aqueous work. A 10,000 vat is now being tried. Above that size the current will be inconvenient. With the small vats four volts per cell is needed, with 10,000 amperes three should do. It is best to count on four; this allowance ought to cover the power for the preliminary electrolysis too. The current efficiency is practically unity. Zinc smoke is of course formed if the temperature is too high. The vats are very simple; merely iron cases lined with fire brick. The chloride soaks into the porous brick and solidifies somewhere, so it is really a vat with zinc chloride walls.

(TO BE CONTINUED.)

*Abstract from Trans. Faraday Society.

Spitzkasten and Spitzlutten.

Written for the MINING AND SCIENTIFIC PRESS.

Spitzkasten consist of a series of devices for concentrating pulverized ores hy means of water. The device is of German origin and has heen in use in Europe for many years. Spitzkasten in one form or another are also in use in many concentrating mills in the United States and elsewhere. The form of construction is various and the principles depended upon to effect the concentration of the material under treatment also vary somewhat. By means of spitzkasten and spitzlutte concentration of the pulp from stamping or grinding mills is carried on continuously and automatically. The spitzkasten as usually made are rectangular boxes having a pointed hottom, into which the pulp is discharged from a launder leading from the mill. In the hottom of the box at the point, or lowest depression, is an orifice which may be enlarged or reduced at will. Through this the coarse material passes, while the finer slimes, remaining longer in suspension in the water, flow out near the top through a launder, and are carried onward for a second or further treatment. Often the hox, instead of having a four-sided, pointed hottom, is simply a V-shaped box, 2 feet or more in depth, with a deeper depression at one end. This is also fitted with an outlet at the lowest point of the box. In some of these classifiers a stream of water under moderate pressure is introduced at or near the hottom, which causes the slimes to continue in suspension longer and consequently effect a more complete separation from the coarse material.

The accompanying illustration (Fig. 1) is that of a classifier employed at the slimes plant of the Zeila mine at Jackson, Cal., and will give an idea of the construction of one of these hydraulic sizers or classifiers. The pulp falling from a launder into the V-shaped hox passes to the first outlet, near the center

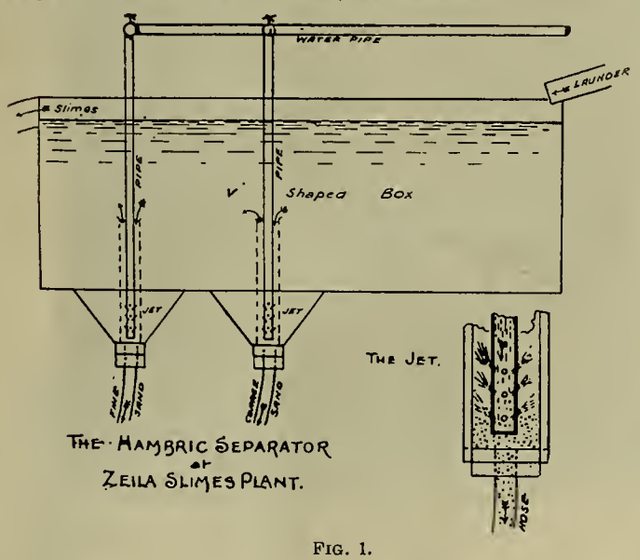


FIG. 1.

of the hox. This consists of a pipe within which is a smaller pipe having perforations, hored in such a way that the water in this pipe under pressure is forced outward and upward in the form of a number of jets, as shown in the smaller sketch. This causes a violent ebullition of the sands, the finer material constantly rising in the outer tuhe and overflowing into the main hox, while the coarse sands pass out at the bottom. The fine pulp from the first pipe seeks the second outlet, where it is subjected to similar treatment, the slimes rising again and eventually finding an outlet through the discharge end of the sizer, while the "middlings" escape from the bottom of the second pipe. The discharge from these pipes may he retreated or not, depending on their value, but the primary object has been accomplished, that of separating the coarse from the fine material, as hoth cannot be successfully concentrated at a single operation. The slimes overflowing from the classifier are sent to the canvas tahles for further concentration by that method.

The spitzlutte is somewhat different in construction, though also of variahle size and form. The spitzlutte is usually (hut not always) cone-shaped. One form of spitzlutte which gives satisfaction is thus described hy H. E. Armitage:*

"The spitzlutte consists of two inverted cones, one inside the other. The inner cone is suspended from the frame hy a threaded bolt EE′ fastened to the crosshar aa′ on the cone. (See sketch, Fig. 2.) The outer cone rests on the dead-water tank cc′. The slimes run into the inner cone and pass out through the perforations B in the hottom, into the space hetween the two cones. Here they encounter an upward current of water coming from the pipe hh′. This pipe is connected with a tank (not shown) at a sufficient height to give the required head. The finer slimes are separated and washed out at the point cc′, where they run into the trough EE′, surrounding the outer cone, and are carried away for suhsequent treatment hy the spout F. The larger and heavier particles of mineral fall into the hopper A, beneath the cones, and are drawn off through the stop cock G on to a jig or other device for further concentration. By raising or lowering the inner cone, hy the screw and nut EE′, the space at the point of discharge can he increased or decreased. It is essential that this annular space he the same area as the area of the circular space heneath the inner cone at H, so that the up-flow of water will be of uniform velocity from the starting point at H to the discharge at cc′. This flow is regulated by means of the valve K, and hy it the percentage of slimes separated can be controlled. The stop cock at G is only opened sufficiently to allow the ore that falls into the hopper A to run off."

The form of sizer above described is hetter suited to the treatment of material containing coarse particles—18 or 20 mesh, as well as slimes—and is adapted to ores which, owing to their tendency to slime, such as galena, gray copper, etc., are crushed through rolls in preference to stamps. The spitzlutte is placed at a point intermediate between the crushing machine and some mechanical concentrating device, usually a jig, hut by careful arrangement

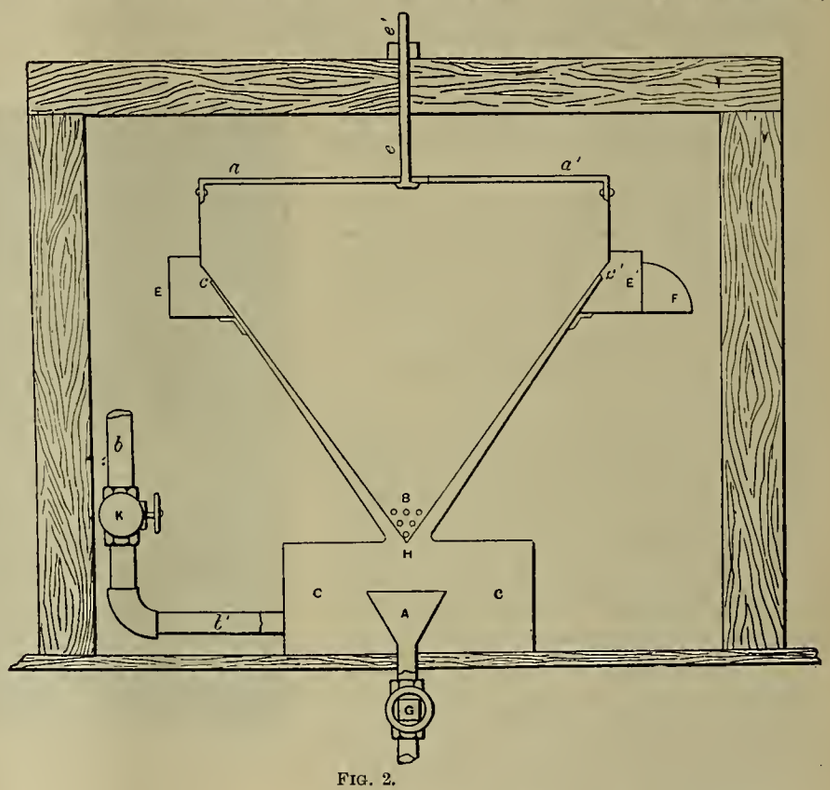

FIG. 2.

it will also size material containing no grains larger than those which will pass a 30 or 40-mesh screen. As will be observed from the ahove, the whole success of the operation depends upon the proper adjustment of the areas through which the material passes. The character of the material under treatment determines the quantity and pressure of water introduced through the clear-water pipe.

Direct Steam Ore Stamps.

TO THE EDITOR:—Mr. Charles H. Fitch, who writes in your issue of July 11 on "Direct Steam Ore Stamps," has paid the writer a compliment which I am ahle to return, and at the same time perhaps contrihute something of interest to your readers, not concerning ore processes of which we know little or nothing, hut by pointing out Mr. Fitch's article as the best example of analytical treatment for prohlems of a "dynamic-economic" nature that has appeared for years.

Constructive engineering work is successful, or otherwise, just as the designer has proceeded hy a logical and analytical course, aided, of course, hy experience, and it is not often that we find in so prosaic a hranch as ore crushing an essay of this nature.

I commend it to the hundreds of engineering students in colleges as a classic in technical literature—one that more than indicates the true and only road to successful design and construction of machines of any kind involving non-computahle forces and ohscure conditions of operating.

The factors are all in, "down to the grease," and the method pursued is the antithesis of the ingenious, contrived of things that see only in one plane, so to speak, and hecomes hy his failures an ohstacle in progress.

There are hlunders enough at hest, even when we proceed hy logical or analytical methods, and understand the limitations of human effort, especially when the very foundations of our physical laws are threatened by radio-activity.

Not a steam stamp or one machine scheme in a thousand is treated as does Mr. Fitch in his essay, and if I am in the mining husiness when he makes the first direct stamp he can enter my order for the machine.

J. RICHARDS.

San Anselmo, Cal. July 31.

The Guadaloupe y Calvo District, Chihuahua, Mexico.*

NUMBER IV—CONCLUDED.

Written for the MINING AND SCIENTIFIC PRESS hy H. Z. OSBORNE.

At Los Tarros there is a 10-stamp mill, idle. Four hours' travel a little west of north of Los Tarros is Bohorigame, in a valley 2 or 3 miles in width, surrounded hy high mountains. Its elevation is 5500 feet. A postoffice is located here, with a semi-weekly mail. It is the center of a rich mineral section.

Three hours west from Bohorigame is Cehollitos, at an elevation of 6500 feet, where is located the Santa Nina gold mine. Considerahle surface work along the vein for 300 or 400 feet was done thirty or forty years ago. Later some Americans sunk a shaft 100 feet, and ran a drift ahout 200 or 300 feet to get under these old workings, which are said to have heen in high-grade ore. They encountered a flow of water, however, which their limited facilities would not permit them to handle, and work was ahandoned.

Ahout two hours south of Cebollitos is the Los Angeles mine, owned hy Dr. Wilson, Mr. Cowan and Mr. Syme, Americans. A considerable amount of development work has been done at this mine, on a vein averaging 4 or 5 feet in width and varying from 2 to 15 feet. Three tunnels have been run, the two first for a length of 300 or 400 feet on the vein, and the third, at a vertical depth of ahout 250 feet, for about 150 feet. A 2-stamp, triple-discharge mill has worked ahout 3000 tons of ore, which is said to have yielded over $40,000, and the tailings are said to assay over $10. The best ore only was worked. The vein is said to average over a half ounce gold throughout.

Southeast of the Los Angeles mine are the old Santa Cruz mine and Mala Noche, the former about two hours and the latter ahout five hours, over rough trails. The mountains in this section are more cut up and uneven than they are east of Guadaloupe y Calvo. Not infrequently there are evidences of mining done in the past, in old tunnels or inclines, and ruins of adohe smelters, or arrastras. The "antiguas" are for the most part silver mines, as the "ancients" did not seem to be attracted hy gold as they are nowadays. There are great numbers of

*See illustrations on front page.

gold veins in this section, but the croppings are generally of low grade, and the Mexicans will not work veins that are not rich enough from the surface to admit of working in tahonas, or arrastras, and when the ore body is worked out, or the pay ends, or water appears, work ceases. As a rule, therefore, very little work has been done on the gold veins. They are generally in porphyry and the gangue is reddish quartz. In the case of the Los Angeles mine the vein is thoroughly oxidized to depth of 200 feet, with no sulphides showing in the tunnel at that level. In other mines, as at the Guadaloupe and Clemencia, at La Cumbre, the sulphides of iron show in less than 100 feet from the surface.

At Santa Cruz is an old silver mine, said to have been a large producer in its day. Between Santa Cruz and Mala Noche are a great many unprospected veins, crossed by the trail. At Mala Noche an American, Mr. Lafayette of Indian Territory, in company with Charles S. Coleman, has purchased a number of "antiguas," carrying copper, silver and gold, of a promising character. It is the intention of the owners to open up these veins, most of which are of considerable size.

From Mala Noche it is two hours south to Cerro Colorado, or "Red Hill." This hill, or mountain, is opposite the old San Manuel mine, which has a history as a silver producer. Red Hill is owned by Americans—George D. Moulton of Dennison, Texas, and T. E. Ivey of Los Angeles, Cal. As its name implies, this hill is distinguished by its red color. It contains several large veins and a good many smaller ones. The Indio is the most promising vein, from 5 to 14 feet wide, and carries gold, silver and lead. La Reforma, another big vein, carries copper and silver, stringers and bunches of which are of high grade. The Plomoso vein is mostly lead. There are a large number of other veins on the hill, but little work has been done on any of them.

About three hours travel from Red Hill, but 2 or 3 miles only distant in a direct line, are the veins of the Rincon de Alisos. There are gold veins, showing some very rich ore at and near the surface. The rich bunches in the Ojito vein are in hematite. The vein is from 2 to 5 feet wide, in porphyry. Higher up on the mountain the porphyry is overlaid with "cantara," and lower down, about 1 mile distant, granite is exposed. La Leona embraces three parallel veins, in a width of 80 feet. These veins vary in width from 1 to 10 feet. They are of black quartz, with a little copper stain. The ore, however, is low grade.

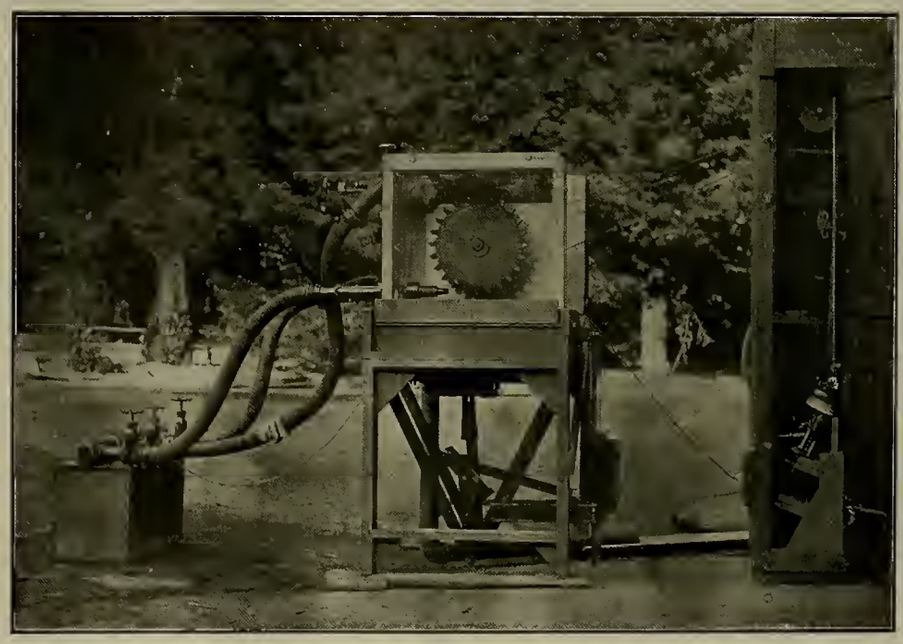
Seven hours southwesterly from Rincon de Alisos is La Cumbre. The trail passes through the hamlet of Cinco Iagus (Five Wounds), crosses the Bazonopa river, one of the forks of the Sinaloa, at Las Placeritas, 3200 feet above sea level, and again ascends the mountains, La Cumbre being 6800 feet above sea level. There are many veins in this section, of which the Guadaloupe, or Fortuna, is the principal one. The Clemencia, owned by a Texas company, of which George D. Moulton of Dennison is the head, has a vein that shows a width of 26 feet, which is apparently an extension of the Guadaloupe, or Fortuna, vein. The Guadaloupe is owned by a New York company, which at the time of my visit had done hut little work on the mine. Its Mexican predecessors, however, had taken out the upper portion of it, where oxidized, for a length of fully 1500 feet or more and worked the ore in tahonas. A magnificent vein is shown, from 8 to 32 feet in width. It is said that the owners of the Guadaloupe will commence extensive work on the mine this fall. There are several other veins that have yielded more or less gold, and a 10-stamp mill is kept employed on ores from the various mines pretty regularly. All the ore is packed on burros from 1 to 3 or 4 miles over steep trails. While packing is done much cheaper than it can be done in the United States, it is still an expensive way to handle ore, and none hut that of good grade can be worked at a profit. Mr. Weed, in the paper heretofore referred to, gave the following description of the geology of La Cumhre mines:

"The older rocks are andesites, altered breccias and lava flows, haked and recrystallized near the diorite intrusions which cut through them. These diorites are coarsely granular, and in appearance are dark-colored granites. Both diorite and andesite were eroded, at a period when the rhyolitic-dacite eruptions began, into a mountainous country as rough as that now seen, so that these recent rocks now covering the summits form the mountain spurs, and are cut into deep canyons by the Bazonopa river. Before the rhyolitic intrusions occurred the country was extensively fissured, and quartz veins were formed traversing the andesites and granites. These veins are particularly large and well developed in the Guadaloupe and Fortuna properties at La Cumbre, and though they pass under the rhyolite caps, and their absolute identity is lost, the group of veins of which the Fortuna is a part can be traced for several miles. Their course is nearly east and west (north 70° east mag.), and the dip is toward the south. The Fortuna vein shows from 8 to 32 feet of quartz, but the hanging and foot walls show decomposed rock, and crosscuts show much alteration for many feet on each side of the vein. This alteration has caused the complete disappearance of the dark-colored minerals of the rock, whose iron has united with the sulphur of the circulating water and formed pyrite, partly in little veins, but mainly as disseminated crystals.

"The vein outcrops are well-defined reefs, which usually stand in relief ahove the slopes. The vein filling consists of white and blue quartz, with pyrite scattered through it, together with some chalcopyrite and zincblende. The capping of oxidized ore is very thin, the sulphides being encountered but a few feet below the surface. Bunches of very rich ore sometimes occur, and usually with a green quartz, colored by a mica, whose appearance strongly suggests the vanadium-mica (roscoelite) which, according to Lindgren, is commonly associated with the richest gold ore of California. This ore and the rosy ore of somewhat lower value often occur as shells encasing nodular masses of zincblende.

"The character of the quartz, the lack of comb structure, and the evidence of replacement of fragments of the crushed granite and andesite, indicate that the vein is largely formed as the result of replacement. The decomposition of the country rock confirms this, and in the coarse-grained granite the character of the vein is identical with the copper veins of Butte, Mont., which are typical examples of replacement veins."

Altogether, the country between Guadaloupe y Calvo and La Cumbre is most interesting, and is likely to develop some valuable mines. Besides the points which I visited, there are several others in the neighborhood which have either developed mines or excellent prospects, as at San Jose, San Juan, Chicuris, Callabocillos and San Jose de Gracia. The mineral belt, with a considerable percentage of gold veins, extends both northerly and southerly from this locality. To the north is Batopilas, Chinipas and Choix, and to the south San Dimas and the rich mines of Durango.



The advantages of this section are a good growth of timber generally throughout the mountains—pine, oak and madrona—and usually the country is well watered. Neither timher nor water is so abundant as it is in the mountain regions of California, but they are incomparably better than in Nevada and Arizona. Labor is cheap—from $1 to $2 Mexican for miners, car men, etc., but, of course, it is not so efficient as American lahor. Nearly all kinds of work are done on a stent system. When a man has drilled the required length of hole or holes, or moved the quantity of ore, his day's work is over. If he fails to perform the required work, it is deducted from his wages proportionately. The climate is generally good in the mountains.

The disadvantages are the difficulties of transportation and the isolation from the world that life there requires. Everything from outside must he brought in on pack mules, and the trip, either from Parral or the coast, takes eighteen or twenty days. The cost is not so great as might be expected, the charges for packing from either Parral or the coast being from $8 to $12 Mexican per carga of 300 pounds. This is a slow way to get in reduction works, but at present it is the only way. An infinite amount of patience and hope, as well as considerahle money and experience, is required for successful mining in this part of Mexico. With this combination, however, I doubt if I have ever seen a country that afforded more opportunities for successful mining ventures than the section of which this article treats.

Tangential Water Wheel Efficiencies.

The above is the title of an exhaustive treatise by Geo. J. Henry, Jr., member A. S. M. E., associate member A. I. E. E., being an experimental investigation of the relative values of different bucket shapes, in the shape of a paper read before the Pacific Coast Electric Transmission Association at San Rafael, Cal., June 16, 1903. It is copyrighted, 1903, hy Geo. J. Henry, Jr. Mr. Henry is the chief engineer of the Pelton Water Wheel Co. In the paper Mr. Henry states that the conclusions arrived at are not "theories deduced entirely on paper, but are the result of an elaborate series of experiments carried out since 1899 in the special laboratory of the Pelton Water Wheel Co., with a view to scientifically and practically determining, beyond a doubt, the relative advantage of different bucket shapes."

"To obtain the best efficiencies it is necessary to have the proper pipe line, gate valves, nozzles, water wheels and buckets, wheel case, wheel pit and tail race, and all of these parts must be properly designed for the particular conditions under which they are to operate, and all will vary with the head or pressure—the water quantity and the revolutions which the wheel is to make. Many a water wheel bucket has been overworked for years, and then charged up with losses that occur because of its being improperly worn, due to this overwork. Again, buckets are frequently charged up with all kinds of losses which are really due to something for which the bucket is not responsible. Pressure, or wheel diameter, or speed on a given wheel, cannot be varied radically without materially altering the efficiency."

One of the Pieces of Experimental Apparatus as Used in the Investigations, Showing the Arc Light and Shutter for Illumination, the Wheel and Nozzle Enclosed in a Plate Glass Case, Prony Brake and Accessory Measuring Apparatus.

In his discussion of the subject, Mr. Henry argues that "to obtain the best possible bucket efficiency it is necessary that the water jet he taken up on the bucket surface and brought to as near rest as possible with the least loss of energy."

The several causes of loss of energy and the methods of correcting those losses are taken up, Mr. Henry stating that "every water wheel plant has all of these losses to a greater or less extent, and it is obvious that when 80% is then obtained from an operating wheel, the improvement of any one of these, or, for that matter, the entire elimination of any single loss, if this were possible, would not, to any great extent, improve any wheel's gross efficiency. The writer has a number of times obtained as high as 90% efficiency in laboratory tests on buckets only."

He continues: "Let us give some attention to the above detailed losses and endeavor, as far as possible, to determine those points, the careful calculation of which will obtain for us the best possible tangential water wheel bucket.

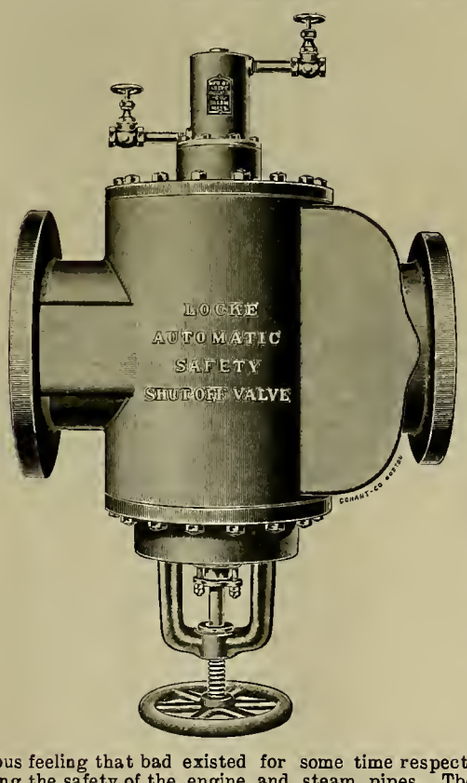
"1. Given a certain stream of water at a given spouting velocity, it is advisable that this be taken upon the bucket surfaces of just enough buckets to catch every particle of water upon the dividing wedges and turn it all on the curved surfaces, and discharge it at just enough velocity (and entirely in a direction at right angles to the entering stream axis) to clear the next following bucket. This resulting velocity will be the tangent of the discharge angle, multiplied by bucket velocity.

"2. The air and surface friction must be main-

tained as small as possible by the use of a nozzle which will give a perfectly circular and solid stream. The bucket surface and cutting edges must be of a shape which, with a minimum wetted surface, will allow the stream, without crowding at any point, to spread out in a thin fan-like discharge on each side. The surface must be such that the water will not adhere, and as smooth as possible.

"The surface may be ground and polished, or better, ground and well painted with a special compound. If all of these points are carefully studied out and the front of the bucket properly shaped and not cut away too low, the imprisoned water will not cause any appreciable loss.

"The windage will also be a minimum if the number and surface of the buckets is a minimum.



"The above losses and considerations for their prevention are all of such a nature, and so entirely interdependent, that their quantitative value cannot be predetermined except in a general way. In designing a water wheel, however, it is certain that the exercise of the most careful judgment is necessary in the laying out of the surfaces, so that all the losses, or at least their sum, or total bucket loss, will be kept down. Thus, if too much bucket surface be allowed, we increase both surface friction and windage for a given output, and if we attempt to cut these down by reducing the surface, we crowd the stream, so that eddy currents will occur and the stream will not properly discharge from the bucket side."

Following is a discussion of different shapes, styles and makes, profusely illustrated, designed to reinforce the writer's argument and conclusions. The forty-three page pamphlet is a notable addition to current technical literature on a subject of great importance to the mining and engineering world.

Locke Automatic Shut-off Valve.

The Locke automatic valve, illustrated herewith, is designed to remedy the number of accidents occurring wherever high pressure steam is being used, and to do away with the dreadful result when the contents of steam boilers are suddenly discharged into confined boiler and engine rooms.

A 12-inch valve of this kind was placed on the steam main at the plant of the Fall River Manufacturing Co., Fall River, Mass., on account of a nervous feeling that had existed for some time respecting the safety of the engine and steam pipes. The superintendent and engineer were standing, one on either side of the steam cylinder of the engine, when, without warning, the cylinder was broken apart across the valve ports. The superintendent states that he supposed they had but a moment to live when he heard what he believed to be a break of the steam pipe, but to their relief they found it was the closing of this large automatic valve. The steam was shut off so suddenly that the men were not even scalded. Since that time this valve has been improved by the addition of a small electric valve by which it may be closed by the pressing of an electric button. These buttons may be distributed about the plant wherever desired, constituting an effective engine stop.

Further protection may be secured by applying their recently patented safety device, by which the engine is stopped when even the cylinder or flywheel develops any weakness, so that the parts start ever so little from their normal position. These valves are constructed with a band wheel and screws so they may be opened or closed in the ordinary manner. They are manufactured by the Locke Regulator Co., Salem, Mass.

Real Values in Mine Management.

Written for the MINING AND SCIENTIFIC PRESS by CHARLES H. FITCH.

To say that a mine requires able, experienced management for its profitable operation is in a way begging the question. It is a trite admission, to which no exception can be taken, but it does not indicate what good management is. We are left to protest:

O tell me not; red roses—
That they are surely red.

We can do better than leave the subject among vague generalities which add nothing to our stock of wisdom.

Success is not identical with good management. More managers have bad their reputations made by rich mines than by management. A man in charge of a rich mine may make mistakes, but the yield covers them up, and there is time for correction. So long as good dividends continue directors do not go behind the returns to seek for machinery of expensive first cost and low efficiency, nor for wasteful metallurgical practice which has lost grip on millions which might have been saved from going "down Lost creek." They let not well enough alone, for the management of some profitable mines has been very defective, and even in these cases the inference of a great manager from a great mine is easy and popular.

On the other hand, a very capable manager may struggle with insuperable difficulties. Such a man, when he ought to receive a crown of glory for producing any dividends at all, is likely to get scant favor and small reputation because dividends are small.

In justice to all concerned, we ought to have some ability to judge, not only from results which depend largely on factors other than managerial ability, but from methods. By analysis of methods we may know whether the best possible is being done with facilities available.

A manager may be anxious for employment and may accept a salary, and may then be pinned down to a hand-to-mouth policy which prevents him from doing well. Such a policy is always uneconomical and can never be justified except by straightened circumstances and the day of small and slow things. Much money is needed to fill out the measure of an able man's ability.

For example, there are in Chicago many smoking chimneys of boilers with cramped settings forced to do excessive work. A stoker, no matter how able, cannot stop the smoking unless he has carte blanche to order larger boilers and better settings. So no capability in the unfortunate man subject to their whims may be able to save the directors, who delude themselves with the idea that they can impose cheap, ineffectual methods upon him, and somehow skim through by luck and escape the losing consequences of such methods. This is worse than pure speculation, acting with admitted unwisdom, and looking to chance to overrule our folly being a shade less excusable than acting in ignorance.

There are a number of leading considerations by which management can be judged, even by persons not expert in technical details. Some of these follow. If the manager is restrained from giving full exercise to the best methods, he can show what he is made of by getting as near the best as circumstances will permit.

1. SIZE.—Operations conducted on a large scale are much more economical than small operations. If a manager does not plan for large operations, if he puts ten stamps here and five stamps there, instead of combining all resources for a large plant, he wastes money. The manager of a large Canadian mine, a few years since, was charmed with the idea of little steam mills and put in a number of them, supposing that they would be as efficient as one large mill. They proved more costly in fuel, in administration and in every way. He deliberately sacrificed the advantage of large units which he might have enjoyed, and the failure of the property is charged to this cause.

The preference for littleness, selfishness, seclusion, a quiet life, etc., are all signs of bad management.

But, on the other hand, prudence will point to awful examples of big mills with no ore supply. This is no excuse for smallness. The ore supply should be first ascertained. A wise manager for a low-grade proposition will say: "We must have a big mill or none. To warrant a big mill we must have a developed mine; that's all." A foolish manager will say: "We will put up a little 5-stamp mill, and get a little money out of the ground, and feel our way. Maybe we have a mine; maybe not." This is not judicious. It is putting smallness forward as a security, while it is really doubly detrimental, both in excessive ton costs and in causing us to shirk our real duty at this stage of the game—the determination of the mine.

2. COST OF CRUSHING.—It is foolish to assume that crushing can be done at "not to exceed $1 a ton." This expression occurs so frequently in prospectuses that it is entitled to the respect due age. Figures for brittle heavy rock crushed coarse in large plants are assumed as applying to tough light rock crushed fine and requiring screening in steps. The latter work may cost $10 a ton, so dreams of profit go glimmering.

In rating capacity look out for specific gravity. Crushing machines make little account of weight. Bulk is what fills them up and rehandling costs enormously. The proper policy is to ascertain degree of crushing truly, and do it on as large a scale as possible, automatically as possible, and with as little repetition as possible.

3. COST OF TRANSPORTATION.—Great economies can be effected by aerial tramways, automatic surface and underground systems, haulage systems, and air and electric trains. Cost of transportation can be made about as little as expense of works will allow. But it is not at all a question of nerve to put in an expensive installation. Heroism is not business. Business wants to be safe. The manager ought to be so much afraid that he will take every precaution. The question is: Can a good profit be made in a transportation investment? Can a larger profit be made with it, interest on outlays and delays considered, than without it? If in doubt we are forced back to the original question, the crux of good management. What mine have we got? What is in it? Is it worth while?

4. COST OF POWER.—The most general answer to the question of transmission is electrical power. This lends extension to water power, but interest on works considered a large compound steam engine can often be made to furnish more power for the money, and in a few years, if not already, gas engines will give water power an even sharper competition. A good manager will look more at the running than at the first cost. A cheap fuel eater will take how much mine working to support? That is a good way to consider it. Putting in a first-class plant, obtaining the chief essentials of economy, is like buying a mine. If the mine pays it is worth buying. But if the profit on the mine is to be run to waste it is love's labor lost.

5. COST OF LABOR.—There may be labor problems which can best be solved by severe discipline, but the great trouble with mine labor everywhere is that it is too low grade. Labor is better humored than fought. Wars are unprofitable. Firmness is essential. A manager who wobbles is like a fly wheel out of balance—no good. Beyond that I believe the hope of this ticklish problem is to bring up the standard of intelligence, of home and family life, independent manliness, benevolent fraternity, insurance against being crushed to the wall. Men are driven to crime by fear. If men are secure they will harmonize and pull all together. This is profitable.

Automatic machinery is worth while wherever it can be introduced. Give a good mechanical engineer your problem. There are many cases where he can put in mechanical devices which will earn splendid salaries, and turn them over to your profit.

6. COST OF ROOFING.—Where a heavy expense of mine timbering must be met there is a greater margin for system and ingenuity to work upon. Gophering, picking the eyes out of a mine and such practices are the reverse of good management, or of any management at all. They are hand to mouth, tentative ways of doing, feeling instead of thinking. Knowledge of the mine, looking to timber supplies from the cheapest source (not always the nearest) and systems planned for continuous breaking down and working, will indicate whether a manager has his business well in hand, or is acting without a definite basis or investigation of the most favorable policy.

7. COST OF HOISTING.—There are a number of questions, such as those of dump, filling and unwatering, which resolve themselves into cost of lifting weight, solid or fluid, hoisting, baling or pumping. One comparison may be emphasized in minimizing these expenses. Pumping with direct-acting pumping engines is notoriously expensive. Hoisting with large compound engines figures out as one of the smallest items of cost in mining. It is the best policy to establish elevations most convenient for surface works and put in ample hoisting plant, and use it for baling, skip hoisting and movement of material on the principle that it is one of the smallest charges against tonnage.

8. SIMPLICITY.—While clear profitable results can sometimes be realized by complex operations, a general prejudice should prevail in favor of simplicity. Large scale and uniform simple order of operations are the story of large, profitable, low-grade mines. The ban should be put on processes, which get into difficulties from which they can be extricated only by operation after operation. Inventors do not sufficiently realize that every step means money lost.

In conclusion, a mine should have a good manager, but it may be set down as axiomatic that no mine which is not well developed can have other than an ignorant manager. A man so situated may be a good man, but until he learns his mine his capabilities as a manager are obscured.

Notes on the Metallurgy of Copper of Montana.*

NUMBER II.

Written by H. O. HOFMAN.

The Montana Ore Purchasing Co. broke ground for smelting works October 17, 1892; first matte tapped January 1, 1893, in seventy-six days. Ore roasted in two Allen - Brown - O'Hara furnaces (hearths 9 by 100 feet, each treating sixty tons in twenty-four hours), and smelted in two reverberatory matting furnaces (hearth 12 feet 10 inches by 20 feet, and firebox 5 by 6 feet; natural draught, stack 80 feet high and 4 by 4 feet in the clear, and charge 7 to 8 tons; time of melting 3.5 to 4 hours) and one blast furnace, 42 inches in diameter at tuyeres. After a year's run, blast furnace replaced by two matting reverberatories like those first built. In 1894, two Herreshoff furnaces (9 feet inside diameter, with five hearths) were added to the roasting department. These giving satisfaction, eight more were erected in 1895 and thirty in 1899, making in all seventy Herreshoffs. The O'Hara's destroyed by fire 1901, and not rebuilt. Early in 1894 hearths of matting reverberatories were enlarged to 13 feet 6 inches by 25 feet, fireboxes, however, remaining 5 feet by 6 feet; at the same time fuel was changed from lump to slack coal, and undergrate blast substituted for natural draught. These changes increased the tonnage per furnace for twenty-four hours by ten to fifteen tons. Furnaces again enlarged, 1898, and two more built, 1899, making six in all (hearth 16 by 33 feet, firebox 6 by 8 feet, stack 80 feet high and 5 by 5 feet in the clear).

January, 1900, two blast furnaces (42 by 120 inches at tuyeres; 11 feet from tuyeres to throat; cast-iron water jackets) were blown in. These water jackets giving much trouble by cracking, furnaces were replaced by larger furnaces (42 by 160 inches at tuyeres and 10 feet 6 inches in height) with steel water jackets. Converting plant started August, 1893, with two vessels of the Parrot type (5 feet external diameter); in 1894, two more were added, and in 1899–1900 four more. Two barrel converters (bowls 10 feet 6 inches long and 7 feet diameter), installed 1901, are in constant use, while the upright Parrot converters are worked only when these are unable to handle all the matte. It is the intention to erect two additional horizontal and to remove the remaining upright converters. Present plant: Seventy Herreshoff roasters, six reverberatory matting furnaces, two blast furnaces, two horizontal and eight upright converters.

The Anaconda Copper Mining Co. has at Anaconda three separate plants, the Upper, the Lower, and the New or Washoe Works. The Upper Works were started by Marcus Daly in 1883 and with fifty-six hand reverberatory roasting furnaces, with hearths 50 by 14 feet, and twenty-eight reverberatory matting furnaces, with hearths 20 by 14 feet. A smelting charge weighed three and one-half tons, and twenty-one tons were treated in a furnace in twenty-four hours. In 1885, two Bruckner roasting furnaces were added. After the fire in 1889, the works were rebuilt and remained practically unchanged until they were closed down in November, 1901. At that time they contained forty Bruckner roasting furnaces with cyliuders 18 by 9 feet, four MacDougall roasting furnaces (16 feet diameter and 21 feet high), with six hearths, four Wethey calciners, with hearths 100 by 12 feet, and 11 reverberatory matting furnaces, with hearths 31 by 16 feet, a matting furnace taking nine-ton charges and treating sixty tons ore in twenty-four hours.

The Lower Works of the Anaconda Copper Mining Co., located 2 miles below the Upper Works, were built under M. Daly by O. Stallmann. The smelting departmeut was started December, 1888, with fifty-six Bruckner cylinders (9 feet 6 inches by 18 feet) and twenty-eight reverberatory matting furnaces, with hearths 22 by 16 feet, a matting furnace receiving six-ton charges and treating forty tons ore in twenty-four hours. The smelter buildings, which were entirely of timber, were entirely destroyed in March, 1889, by a fire which started in the coal bins. They were quickly replaced by a steel structure. In 1890, forty Bruckner furnaces of the same size as the first ones were added to the plant, and in 1899 were added four MacDougall furnaces of the Evans-Klepetko pattern (16 feet diameter and 21 feet high), with six hearths. Of the twenty-eight original matting furnaces, seven were enlarged in 1899; three had hearths 32 by 18 feet, 33 by 18 feet and 45 by 18 feet; and four, hearths 35 by 18 feet. They were charged with about eleven tons of ore and averaged seventy-five tons in twenty-four hours.

The converter plant was started in 1890 with fifteen stalls for upright vessels, 10 feet high and 6 feet in diameter. In the same building were six blast furnaces 8 feet by 3 feet 6 inches at tuyeres and 10 feet high.

New Electrolytic Refining Plant, still in full operation, started in 1894, refines part of the converter copper of the Washoe works, the rest being shipped to Baltimore for treatment. The old experimental plant, started in 1891 and closed in 1893, contained 630 tanks.

The New or Washoe Works of the Amalgamated Copper Co. were planned and erected by F. Klepetko. When the Amalgamated Copper Co. obtained control of the Anaconda and Washoe Companies, it was decided to erect new works instead of remodeling and enlarging those of the Anaconda Co. The works were started in 1902, contain forty-eight six-hearth MacDougall-Evans-Klepetko roasting furnaces, 16 feet diameter and 21 feet high; five blast furnaces (56 by 180 inches at the tuyeres and 14 feet 10 inches high); fourteen matting reverberatories (hearth 20 feet by 51 feet 2 inches) and eight converter stands (barrels 12 feet 5 inches long and 8 feet in diameter). The fumes from these four departments are drawn off by four stacks, 200 feet high and 23 feet 6 inches inner diameter, the lower 20 feet being lined. As the fumes damaged the crops in the Deer Lodge valley, it has been decided to deliver them 500 feet higher up into the air. The fumes from the four departments will be conducted through branch flues into one brick main, 2300 feet long, built on a hillside, and ending in a stack 300 feet high and 30 feet inner diameter. The main will be 37 feet deep; the first 1300 feet will be 60 feet wide, and the remaining 1000 feet 120 feet wide. Underneath will be a tunnel to receive the cars, into which will be discharged the flue dust. It is expected that the new addition will be finished this summer (1903).

Boston & Montana Con. Copper & Silver M. Co.'s Great Falls Plant.—Ground broken in the spring of 1890. Plant first consisted of twenty-four Bruckner roasters (cylinders 8 by 16 feet), eight tilting reverberatory matting furnaces (hearth 13 by 16 feet) and two five-ton upright converters. Matting furnaces, having regenerative chambers and fired with producer gas, resembled the Campbell open-hearth steel furnaces. Plant has been greatly enlarged since 1890, under the management of F. Klepetko, and furnaces much changed to meet constant demand for increased capacity. Present plant: Twenty - four Bruckner cylinders (8 by 16 feet), all idle except two or three used for drying slimes from the concentrator; eighteen six-hearth MacDougall-Evans-Klepetko roasting furnaces (16 feet diameter and 21 feet high); five gas-heated stationary matting reverberatories with regenerative chambers, four of which have hearths 42 feet 6 inches by 15 feet 9 inches, and one has a hearth 29 by 12 feet; five blast furnaces (18 feet high to charging floor, four are 56 by 180 inches, and one 44 by 180 inches at tuyeres); twelve five-ton upright converters (7 feet diameter and 14 feet 7 inches high); one anode casting reverberatory (hearth 14 feet 8 inches by 22 feet 6 inches) with Walker casting machine; and an electrolytic copper refinery with 312 tanks and four copper refining furnaces of different sizes.

The early history of this company may be summarized by the beginnings of the several operations: Concentrator, March, 1891; Bruckner cylinders, April, 1892; reverberatory matting furnaces, April, 1892; converters, August, 1892; blast furnaces, April, 1893; refining furnaces, January, 1893; electrolytic refinery, February, 1893.

Nearly all the smelting works have concentrating works.

THE ORES.—The ores of the Butte district are classified by Goodale as copper-silver ores, silver-copper ores and silver ores. The copper-bearing minerals of the copper-silver ores are chalcocite, bornite, enargite and chalcopyrite; the gangue is quartz and feldspar. The copper and silver-bearing minerals of the second class are wurtzite, sphalerite, bornite, chalcopyrite, pyrite, tetrahedrite, enargite, tennantite and galenite; the gangue is quartz and feldspar, with some barite and fluorite. Of the silver ores, which are of secondary importance, the silver-bearing minerals are pyrite, sphalerite, galenite, tetrahedrite and argentite; the gangue is quartz, rhodocrosite and rhodonite. With regard to metallurgical treatment, the copper-bearing ores are divided into first and second class. The line of division varies with the different mines. In general, first-class ore contains 10% to 15% copper and is smelted direct, usually in the blast furnaces, without having been roasted. Second-class ore, which forms about 90% of the ore mined, contains 3% to 6% copper and is concentrated; five concentrates are always roasted and, as a rule, smelted in the reverberatory matting furnaces; coarse concentrates, about 5 mm. in size, are often added to the blast furnace charges without having been roasted, the amount charged reaching 30% to 35%.

METALLURGICAL TREATMENT. — The metallurgical processes in the Butte district show much uniformity with regard to the general principles on which they are based. They comprise roasting, smelting, converting, electrolytic refining and casting. There is considerable diversity in the details of practice.

First-class ore, forming about 10% of the product of the mines, is, as a rule, smelted raw, and furnishes the desirable coarse ore of the blast furnace charge. Concentrates, coarse limestone and converter slag are the basic fluxes added to slag the siliceous gangue. In one instance, some first-class ore is roasted in lump form in stalls. This makes it less refractory than raw ore, and, furnishing available iron, permits the running of slags richer in iron, and hence more fusible than would be otherwise possible. Heap roasting, practiced in the early days, has been abandoned.

In crushing, the copper-silver ores readily break into small grains, making often more fines than can be carried by a stall or even by a blast furnace. This necessitates separating part of the fines by screening, the screenings going into the fine-ore roasting furnaces.

The form and general arrangement of the open stalls now in operation are the same as given in Peters' "Modern Copper Smelting." The management differs from the description given by him. In making the bed of decayed wood, first used by A. J. Schumacher at the Parrot works, no attention is paid to an open cross channel to start the fire. While Peters prefers to close the front of the stall with large pieces of lump ore, at Butte it is closed down to 2 feet from the bottom with a plate of sheet-iron, which is braced by iron cross-bars to prevent bulging, caused by the swelling of the ores while roasting. The plate is supported by blocks of wood, between which are placed small sticks and kindling. During the roast, when the contents of the stall has risen to the highest point and begins again to shrink on account of the slight clinkering which always takes place, the front plate gradually glides down to the floor. A stall holding thirty tons of first-class ore, with about 10% of copper and 30% to 35% sulphur, burns thirty days, the sulphur being reduced to 3 5% to 4%.

The fine-ore furnaces are represented by four types, the Allen-O'Hara, the Wethey, the Pearce and the MacDougall; long-hearth reverberatory furnaces, used in early times, having been given up entirely.

The Allen-O'Hara furnace is one of the improvements on the original O'Hara furnace. The two superimposed hearths are each 9 by 90 feet; the six carriages, with their plows, make the circuit in three and three-fourths minutes. Thus the ore, lying 3 inches deep, is stirred every thirty-seven seconds, and remains about six hours in the furnace. A test showed that 3.64 H. P. was required to run the furnace. The ore charged is a mixture of concentrates and fines from first-class ore, usually in the proportion of 4½ : 1, containing about 35% sulphur.

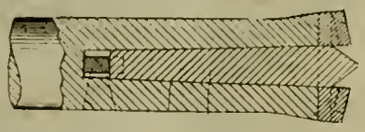
From forty-seven to fifty tons of charge is roasted in twenty-four hours, or sixty pounds per square foot of hearth area, the sulphur being reduced to 8%. One hundred pounds moist ore gives 72.7 pounds of calcines and one pound of flue dust. A furnace is attended in an eight-hour shift by one-half car-man, who brings the ore; one-half fireman; one wheeler, who removes the calcines to the smelting department; and one-eighth repair man, during the day shift only. A partial analysis of an average sample of roasted ore gave: Cu, 10.8; SiO_2, 31.6; Fe, 38 0; S, 7.6; Ag, 7.3 oz. p. t. One of flue dust: Cu, 10 8; SiO_2, 34.4; Fe, 36.5; S, 8 2; Ag, 7.2 oz. p. t.

The Wethey furnaces in operation each have four superimposed hearths. The furnaces erected in 1894 had two sets of hearths, each 50 by 5 feet, with the rabble carriages running between them, the arms projecting from the inner sides into the hearth. The furnaces, erected since 1894, have been increased to 65 by 10 feet, with the rabble arms protruding on both sides and carried on carriages on the outside of the furnace hearths. The tripping doors, which close the continuous hearth slot, are not being repaired as they wear out, the furnace seeming to do satisfactory work without them. The position of the firehox, which was built at first to heat the second floor, has been changed so that the flame may enter the top hearth and dry and kindle the moist concentrates and slimes as they enter the furnace. While the smaller size furnace, with a hearth area of 2000 square feet, puts through at the present time sixty tons of raw material with 35% sulphur, or sixty pounds per square foot of hearth area, reducing the sulphur to 8%, and consuming 5.5% of slack coal, the larger size furnace, with an area of 2600 square feet, roasts in twenty-four hours ninety tons of ore, with 35% of sulphur, or seventy pounds per square foot of hearth area, reducing the sulphur to 5% to 6%, and consuming somewhat under 4% of slack coal. One fireman attends each furnace.

The improvement in the work of the longer furnaces is due to the heat from the firebox having to travel a longer distance before it escapes to the flue, and to the ore traveling in a direction opposite to that of the flame, whereby the heat is more fully utilized than with the shorter furnace.

The Pearce Turret furnaces of three kinds are roasting ores, the single and double-deck furnaces of R. Pearce and the six-deck furnace of R. F. Pearce. A single-deck furnace, 36 feet in diameter, with a 6-foot hearth (or a hearth area of 505 square feet) and two stirrer arms, roasts in twenty-four hours fourteen tons of concentrates (Cu, 7.0%; Fe, 24.0%; Zn, 12.0%; S, 32.0%; SiO_2, 23 0%; Ag, 14 oz. per ton), reducing the sulphur to 7% to 8%, and burning 400 pounds of coal per ton of ore. The percentage of flue dust is very low.

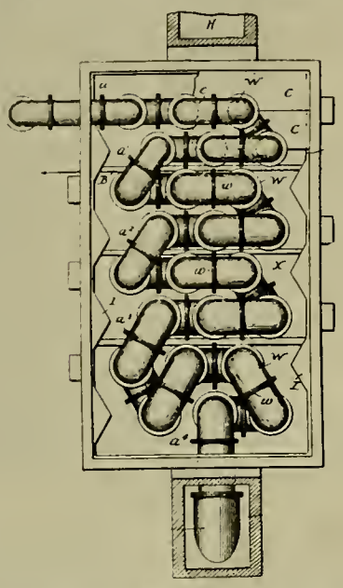
(TO BE CONTINUED.)



*Trans. Am. Inst. Min. Engs. (Condensed).

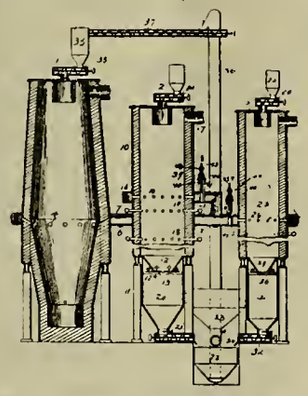
Mining and Metallurgical Patents.

PATENTS ISSUED JULY 28, 1903.



Specially Reported and Illustrated for the MINING AND SCIENTIFIC PRESS.

ROCK DRILL BIT.—No. 734,515; H. Collins, Witwatersrand Gold Fields, Transvaal, South Africa.



In hand rock drill or rock drill bit combination with drill or bit formed with angular grooves or slots across end thereof made tapering from center to edge of drill, of removable cutting teeth having bases made with corresponding taper in direction of lengths and adapted to be fitted into tapering angular grooves in drill end and means, located in center of drill, engaging inner ends of teeth to lock in position.

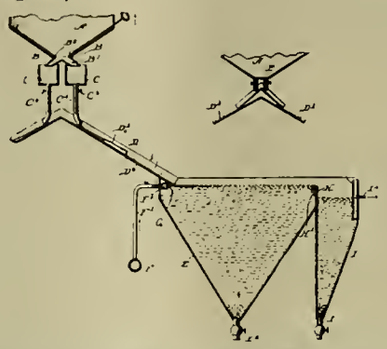
COMBINED HOT BLAST OVEN AND DUST COLLECTOR.—No. 734,523; H. W. Edwards, Oakdale, Ga.

Combination of chamber having inlet and outlet for hot furnace gases, of series pipes arranged vertically in staggered relation within chamber, and connected to form continuous conduit for blast, and means for supplying blast to end pipe nearest outlet of chamber, pipes offering less obstruction to passage of gases at outlet end of chamber than at inlet end.

SMELTING APPARATUS.—No. 734,594; P. Naef, New York, N. Y.

Smelting apparatus consisting of blast furnace, coking oven and limekiln, means for conducting gas from blast furnace to coking oven and limekiln, means for mixing solid products from coke oven and limekiln with ore, and means for conducting mixture to and discharging into blast furnace.

PROCESS OF MAKING BRICKS FOR REFRACTORY LININGS OR OTHER USES AND THE PRODUCT THEREOF.—No. 734,458; E. W. Engels, Dusseldorf, Germany.

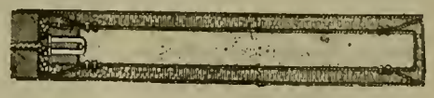


Process of producing bricks for refractory furnace linings, which consists in applying to surface of unburned brick, while in a plastic state, carborundum, and forcing carborundum into surface by pressure, before firing brick or body, subsequently firing or burning brick or body at a temperature less than that of electric arc for producing highly refractory surface which does not readily crack or separate from less refractory and more fusible interior portion.

AMALGAMATOR.—No. 734,618; G. C. Scott, Columbus, Ohio.

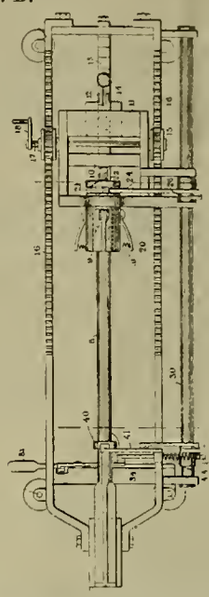
In amalgamator, combination with opposite supports, of bearings thereon at different elevations, polygonal rotatable casing between supports, tubular journals piercing respective ends of casing and mounted to rotate in adjacent bearings, upper journal forming an inlet and lower journal outlet, series of longitudinal spaced parallel amalgamated plates extending from side to side of casing with ends of series terminated short of ends of casing, tubular journals communicating with respective spaces between corresponding ends of casing and series of plates, baffle disposed across inner open end of tubular inlet journal, side walls of casing being provided with discharge openings at lower end thereof, cage carried by outer end of discharge journal, normally closed valve for journal, adjustable screw-threaded stem piercing outer wall of casing, and spring connecting valve to stem.

ORE SEPARATOR.—No. 734,641; C. F. Wheelock, Birmingham, Ala.



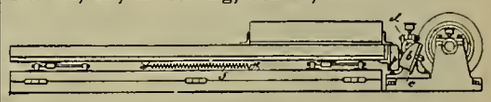
Combination of vessel adapted be filled with water and provided with means for precisely determining level of water, chute declining toward and adapted to reach level; transverse water pipe slightly below water level, approximately parallel with and proximity to discharge edge of chute discharging laterally in same general direction as chute; means for delivering water under pressure to pipe; means for regulating pressure; and means for causing thin uniform stratum dry graphite to descend chute.

ROPE SOCKET SWIVEL.—No. 734,664; H. M. Brittan, San Francisco, Cal.



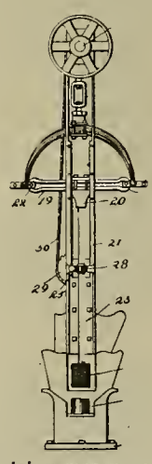
A rope socket swivel for well drilling apparatus, comprising shell provided with cylindrical chamber, rotary piston mounted in chamber, piston having longitudinal bore in which drill rope attached, and means of locking piston to shell to prevent relative rotation of parts, whereby device may be employed as swivel connection or as rigid connection.

SAFETY BLASTING CARTRIDGE.—No. 734,684; T. F. Durham, Philadelphia, Pa.



In blasting cartridge, inner and outer receptacle, each having closed lower end, fire-extinguishing agent in outer receptacle in which inner receptacle is immersed, explosive in inner receptacle, arms on ends of inner receptacle each of which extends diagonally beyond end of inner receptacle and engages ends of outer casing at inner periphery thereof.

DRILL SHARPENER.—No. 734,708; J. H. Hicks, Central City, S. D.



Combination with means of supporting cutting end of drill, of spring actuated means for elevating drill, and means actuated by operator for intermittently rotating and depressing drill.

HEAD MOTION FOR ORE CONCENTRATING TABLES.—No. 734,758; L. Searing, Denver, Colo.

In head motion for ore concentrators, combination of part to be actuated, and variable speed actuating means, consisting of curved reciprocating shoe for varying in one direction of movement of actuated part and at speed gradually increasing throughout, movement relative motion of shoe and part to be actuated, by shifting point of contact between the two along surface of part to be actuated during reciprocation.

STAMP MILL.—No. 734,828; W. A. Dalton, Tucson, Ariz.

In stamp mill, driving means, comprising in combination connecting rod adjustably clamped to bowed spring carrying at outer ends flexible members attached to crosshead in which is revolubly mounted stamp stem, crosshead, bowed spring, flexible connections between ends thereof and crosshead, crank shaft connected with spring, means for adjusting connection between spring and crank shaft and for rotating stamp stem, consisting of vertical worm gears on stems and horizontal worm engaging gears, worm being driven by crank shaft.

Mining Summary.

Specially compiled and reported for the MINING AND SCIENTIFIC PRESS.

ARKANSAS.

BOONE COUNTY.

The Renner tract of 280 acres of mineral land, 5 miles east of Lead hill and south of the Washington mine, was sold last week to Baxter county parties.

SEARCY COUNTY.

The Maumee M. Co. of Harrison have decided to proceed with the erection of their concentrating mill, says Manager Hamilton.

NEWTON COUNTY.

M. Kaufman, of Dardanelle, has bought 200 acres of mineral land near the Speers mine at Yardelle, for a company of Arkansas valley men. He also bought the G. H. Cotton and C. S. Denton tract, 390 acres for $8560.

ALASKA.

J. P. Frizell of Portland, Or., reports finding on Unimak island, one of the Aleutian chain, extensive deposits of carbonates of iron of good grade.

A strike of ore is reported in the Eureka mine, near Juneau, at the 550 foot level, which averages $28 in gold per ton. This ledge outcrops on the surface 50 feet wide, says Manager T. V. Newell.

Dawson advices state returning Tanana stampeders say the wash up to June 16 was: Pedro, 2000 ounces; Gold Stream, 1000 ounces; Clear creek, 200 ounces, and Forks, 100 ounces.

ARIZONA.

COCHISE COUNTY.

F. A. Storm of New York, manager of the reorganized Copper Belle M. Co., is arranging for the renewal of operations at their group at Gleeson.

At the Middlemarch mine, near Bisbee, Superintendent O'Gorman reports having developed a flow of 50,000 gallons of water per day, which is more than enough with which to operate his concentrators.

M. C. O. Rollins and S. S. Sutton of the Crescent Copper Co. have an option on sixteen claims in the Modern district, 12 miles from Bisbee.

GILA COUNTY.

R. Fleming, mine superintendent of the Black Warrior C. Co., near Globe, says little is being done at Black Warrior at present, but by September 1st construction work will begin on the 100-ton blast furnace to be added to their smelter equipment.

GRAHAM COUNTY.

G. C. Gill, president of the Shannon Copper Co. at Clifton, says preparations are being made to build another concentrator—a duplicate of the one put up last year. The company is producing sixteen tons of copper daily.

A temporary injunction has been issued against the Standard Copper Co. of Clifton in favor of W. B. Thompson, to prevent them from taking ore from the San Jose mine, near Clifton, pending the settlement of a suit to quiet title to the same, which will be tried in October. The case will involve property valued at $270,000.

MARICOPA COUNTY.

(Special Correspondence). — It is reported that a deposit of tin ore has been found north of Phœnix.

Phœnix, Aug. 2.

(Special Correspondence).—The development work is going ahead at the Vulture mine near Wickenburg, says Manager Sanders.——Mills & Philes are working a group of gold and copper properties in the Cave Creek district.——W. L. McKay is taking out copper ore for shipment from his claims near Cave creek.——B. Ford has men at work on his mines in the White Tank mountains, west of Beardsley.

Wickenburg, August 3.

At the Angel mine west of Wickenburg, operations are being resumed under direction of S. C. Bird, of Bridgeport, Conn. He says an arrangement has been made with the Wickenburg smelter for working of Angel ores. There is ore on the dump that will he shipped to the smelter.

The Haxworth group of twenty-five claims at Agua Caliente has been sold for $100,000 to T. James of Chicago, Ill., and C. T. Kenman of Milwaukee, Wis.

MOHAVE COUNTY.

(Special Correspondence). — Hawks & Shaefer have their whim at work on the Tintic mine, near the Merrimac mine, near Chloride. The underground workings are flooded and as soon as they are unwatered and the drifts cleared of debris development will be resumed by drifting from the 90 foot level of the shaft. The ores carry $100 per ton in gold, with some silver.

W. J. Cleeland of Philadelphia, Pa., president of the Philadelphia & Arizona M. Co., says work will be resumed on the Minnesota mine, which has been closed since spring. Forty men will be put on and it is intended to drive the drift on the 600-foot level ahead, and to go down 400 feet deeper in the main shaft. Large bodies of milling ore are said to be showing in the lower workings.

The new silver prospect which is being opened up northwest of Chloride, near the Juno mine, by J. Carroll is reported improving. Sinking continues.

Hughes & Mitchell continue in ore on the Century mine, near the Altata. The new shaft is down 65 feet, where there is a body of ore of shipping grade 2 feet wide. The ore is a mixture of horn silver and iron carbonates. A shipment of the ore, which is mostly on the dump, will be made next week.

The first half of the 100-foot contract for sinking the 140-foot shaft on the Sunrise mine, below Chloride, is finished and a large body of ore is being opened up. J. Barry of Los Angeles, Cal., is owner of the property and is superintending the work. He says development work will be increased and the Sunrise will become one of the steady shippers of the camp.

J. Dixon reports mining operations active around Cerbat. He is taking out high-grade gold ore in developing the mine, which he owns. The gold values, however, are decreasing and are being replaced by silver. Sinking will continue and drifting will be started.

Only two of the leading mines are being worked at Stockton Hill, the Earl and the De la Fountaine. Both of these have a large number of men at work and making good shipments of ore.

Chloride, Aug. 3.

At the Great West mine, in Weaver district, near Kingman, the Pacific Reduction Co. is preparing to build its reduction plant. Scarcity of water is one of the drawbacks. The ores carry values in gold.

The Marquette Exploration Co., of Chicago, Ill., who have bonded for $250,000 the Dempsey & O'Dea group of claims in San Francisco district, 9 miles west of Chloride, are making preparations to increase development work.

PINAL COUNTY.

(Special Correspondence).—The Copper Buttes M. Co. have seven men at work sinking a shaft on one of their claims, 8 miles west of Kelvin.

Kelvin, Aug. 2.

The Christmas Gift gold mine, 30 miles south of Casa Grande, was bought last week by the Platt Cobre M. Co. of Denver, Colo. The property is considered of great value. Complete equipment and operations will follow.

J. W. Sisson, of New York, president of the Troy-Manhattan C. Co., reports work progressing in their mines at Troy. In the Alice mine, the Alice tunnel is being driven from the west side of the mountain to cut the Alice vein at depth of 800 feet, and will be some 1700 feet in length. Through it, all the ore from the mine will be delivered into bins at the tunnel portal and conveyed by aerial tramway to the reduction works to be built on the Gila river. The Prescott & Eastern railroad, under construction, will pass within a few miles of the Troy mines.

SANTA CRUZ COUNTY.

Superintendent J. A. Fraser says the Ragnarok mines, in the Oro Blanco district, have been sold to D. H. Jennings of Bridgeport, Conn., and J. T. Quinlan, E. L Foster, F. M. Bishop et al. for $150,000. There are three veins on the Ragnarok which will furnish a good tonnage of free-milling ore. Operations will be started this week and machinery put in for the treatment of the ore. Oro Blanco is 75 miles south of Tucson and just over the Pima county line in Santa Cruz helow Arivaca.

YAVAPAI COUNTY.

The Rapid Transit M. Co. has thirty hurros packing ore from the mine to Middleton station, on the Bradshaw Mountain Railroad, from which point the ore is shipped to the smelter. The railroad will be continued to Crowned King and a wagon road will be built to the Rapid Transit by the way of Gray Eagle and Tiger, making a short haul from all mines in Oro Bella hasin, says the Prescott Courier.

YUMA COUNTY.

The Belle of Arizona group of gold-bearing quartz claims, 2 miles from the Guadaloupe mine, and 8 east of Quartzsite, have been bonded to W. M. Kellogg of Hartford, Conn., for $25,000.

The Socorro mine at Harrishurg has shut down for an indefinite period, the management reporting labor troubles as the cause.

In Cunningham pass, 2 miles from the Bullard mines, near Harrisburg, the Bill Crown and War Eagle group of sixteen claims has been sold to Eastern men and the Bill Crown M. Co. incorporated, with F. C. Smith of Chicago, Ill, R. Dunlap and R. F. Lintermann of Chicago, Ill., as officers.

The Ward group of mines, above the Socorro mine, near Harrishurg has been bonded to G. W. Middleton of Prescott, and men have been put to work running a tunnel, which at 300 feet they expect to cut a ledge of free-milling ore.

CALIFORNIA.

AMADOR COUNTY.

At the Fremont Con. mine at Amador City work on the 40-stamp mill is progressing and part of the machinery is on the ground. The gallows-frame is finished and is 96 feet high.

W. A. Nevills says arrangements for starting work on the Moore mine, south of Jackson, have been completed. Timbers for the repair of 500 feet of shaft are ready to be shipped to the mine. The uncertainty of the labor situation is the only drawback.

The Climax mine, east of Jackson, has been bonded to P. B. Aiken et al. of San Francisco, who have started development work. The property was formerly known as the Reed & Askey.

At a meeting of the directors of the Lincoln Co. at Sutter Creek, held last week, it was decided to close down. The work of taking up the track is in progress.

BUTTE COUNTY.

L B Johnson, assistant superintendent of the Gold Bank mine, near Forbestown, owned by H. P. Stow, reports work progressing. A number of ledges may be most economically worked by driving the Gold Bank tunnel through the mountain and building a mill at its mouth. This would do away with hoisting expenses and give greater fall to the water which drives the present mill. A power plant at the mouth of the tunnel would develop five times the power now developed at the present mill-site without adding to the water supply. The Gold Bank tunnel is driven into the mountain 750 feet vertically below the collar of the Gold Bank shaft and is 2300 feet in length.

CALAVERAS COUNTY.

The Angels Quartz M. Co at Angels report they intend to add another twenty stamps to their mill, the work of grading for which was started this week.

EL DORADO COUNTY.

The Rescue M. Co. has been organized by A. F. Anable of Rescue and J P. Vane of Oakland, with R M. Crackles, P. A. Marriotte and W. E. Reed, and has bought the Coon Crossing gold quartz mine, near Rescue. They will begin development next week. The ledge, averaging 20 inches in width, is of high-grade ore. A F. Anable, superintendent of the Golconda mine, near Rescue, will superintend the development work at the Rescue. They intend to put up a 5-stamp mill, to be operated by either steam or gasoline. The following are the directors: R. M. Crackles, P. A. Marriotte, W. E. Reed, A. F. Anable and J. P. Vane.

Thirteen men are at work at the Noonday copper mine near El Dorado. The road to the mine is being repaired by the company, preparatory to hauling out the ore for shipment.

A new three-compartment shaft will be sunk on the Darling mine, east of Georgetown, says the Gazette.

FRESNO COUNTY.

The Chicago West Point, Chicago Limited and Chicago Reliance companies, operating near Coalinga, have been consolidated under the name of the Chicago Con. Oil Co.

J. A. Bunting and M. Scott have bought the controlling interest in the Esperanza Oil and Gas Co., operating at Coalinga. The Esperanza has two flowing wells of 19° gravity oil, producing 400 barrels each per day. Its No. 3 well is in the oil sand, with good indications.

KERN COUNTY.

The Junction Oil Co., near Bakersfield, has its fifth well down 650 feet and the sixth rig is being built.

The California Kern Oil Co., operating at Kern river near Bakersfield, are preparing to build a refinery on the property. The company has completed its second well.

C. H. Congdon, superintendent of the Union Pacific Oil Co, operating in the Carisa district, 6 miles southwest of McKittrick, reports operations resumed.

The Potomac, in Kern River field near Bakersfield, is again placing all its wells "on the beam," abandoning the use of the air compressors after two years' trial, says Manager Morton, the reason for this being that the compressor requires too much submersion, while on the beam the well can be pumped dry. The Mercedes and Globe companies are still using the air compressor, and the Potomac increasing its boiler capacity.

MARIPOSA COUNTY.

Manager Ward has resumed operations at the Pinon Blanco mine, near Coulterville.

MONO COUNTY.

The cyanide plant at the Dunderburg mine, near Bridgeport, was totally destroyed hy fire last week; cause unknown. Preparations were being made to begin working of tailings and some of the tanks had been filled.

NEVADA COUNTY.

The Sixteen-to-one mine at Gaston resumed work last week, says Manager Eagan, of Sacramento, who is at the mine.

Manager G. Lezinsky of the Gold Tunnel M. Co. says they have taken possession again of the Orleans mine, on Gold Flat, near Nevada City, the Baldwin lease having expired. Arrangements will be made for sinking a new shaft and the ledge developed.

It is expected that operations will be resumed at the Eagle Bird mine, near Maybert, which is owned by an Eastern company, and which has for three years past only kept its pumps moving, says Foreman Wilson.——At the Gray Eagle the 10-stamp mill has been running steadily with satisfactory results, says Superintendent H. Kalaher. The Gray Eagle is worked through a tunnel.

The mill at the Last Chance mine, near Nevada City, will be started up this week. Considerable development work will be done.

Superintendent E. M. Labadie, of the Grass Valley Con. mine, near Grass Valley, owned by J. M. O'Brien, of San Francisco, has started sinking another shaft 300 feet from the old one. He has men at work on the 800 foot level raising on the hanging wall. Heavier machinery will be put in.

At the Hudson mine on Deer creek, below Nevada City, work is progressing. The pumps have been taken out of the old shaft and are being set up in the three-compartment shaft, and the hoist from the incline shaft also moved. The entire plant is to be run by water power under a 400-foot head.

Manager Hay of the Ironclad mine at Rough and Ready has bought 120 acres of land on Randolph flat and will put a hoisting and pumping plant on the Reese shaft, which will be reopened.

PLACER COUNTY.

G. Skidmore of North Bloomfield has bought a half interest in the T. Power gravel mine, at Iowa Hill, and development work will be increased.

A rich body of gravel is reported struck on the Peckham Hill property at Spring Garden, on the Forest Hill divide. The group is composed of a number of claims, aggregating several thousand acres, and owned by A. C. Burrage of Boston, Mass. The tunnel is going ahead, says Superintendent G. McAulay.

SAN BERNARDINO COUNTY.

J. Goldsmith, manager of the Tennenbaum turquoise mines, near Manvel, says he has resumed operations on their group.

SANTA BARBARA COUNTY.

On the Western Union Oil Co ground near Santa Maria there are seventeen wells, and the company propose to sink more. Well No. 13 will be made a test well and they will go down 3000 feet. The work will be done with the rotary drill. Most of the company's oil is being sent through the pipe line to Careaga, from which place it is pumped to Alcatraz, and thence loaded on deep sea vessels, says A. J. Osgood, superintendent.

SANTA CLARA COUNTY.

(Special Correspondence) —The Quicksilver M. Co., operating the New Almaden quicksilver mines, are handling an output of 4000 tons of ore per month. The ore carries the cinnabar in disseminated particles, and is reported to run 0.5% in mercury.

They have six furnaces in operation, two of which are of two compartments and one of three compartments. They have an ample water supply. At the mines the ore is being taken out partly through shafts and partly hy tunnels. T. Derby is superintendent.

New Almaden, Aug. 6.

SHASTA COUNTY.

The Shasta King mine, near De Lamar, is reported closed down for the present.

At the Anchor mine, in Buck gulch, near De Lamar, connection has been made between the tunnel and the shaft. Ore taken out during the driving of the tun-

nel is being taken back in 500 feet, hoisted 270 feet, dumped into bins, hauled one-third of a mile in wagons and sent to the smelter, says Superintendent H. C. Anchor. He expects to make an output of fifty tons a day.

SIERRA COUNTY.

At Poker Flat, near Downieville, the Poker Flat M. Co. are putting in a roller quartz mill.

F. P. Roddy et al., who have bonded the Willoughby mine, near Gold Valley, have men at work preparing to open up the mine. J. B. Lasslat is superintendent.

SISKIYOU COUNTY.

P. S. Gallagher, of Cherry Creek, near Yreka, sold two of his claims to C. Paige last week. Gallagher says he will put men at work sinking a shaft on his McCormick mine.

The work of running a tunnel in the Headwaters quartz mine on Humbug creek, near Yreka, is progressing and they expect to strike the ledge at 200 feet. The company has a mill on the ground with steam engine and boiler, ready to start orushing at any time.

TUOLUMNE COUNTY.

(Special Correspondence). — John A. Neale of Sonora is mining on town lots in the center of the city of Sonora. For years these lots were covered by business buildings, but they were destroyed by fire in 1900, and the owner is now placer mining on the site of the buildings. Besides a large return in coarse gold, Mr. Neale has found a considerable sum of money in coin. Many of the coins are gold, and both gold and silver coins are of many foreign countries. Mr. Neale says the result of mining operations on these lots will more than pay for rebuilding the structures destroyed by fire. He is also working the Neale pocket mine, formerly the Sugarman, on Bald mountain, near Sonora. This mine has produced many thousands of dollars in crystallized gold and tellurium.

Sonora, Aug. 3.

W. Floyd has bought the Sharwood & McTarnahan two-third interest in the Garfield quartz mine, south and adjacent to the Grizzly mine, near Carters, for $5000. A. B. Smith has bought the Collins half interest in the Annie Belle gold mining claim on Mt. Eaton, near Carters.

B. Kolich of Columbia has bought a one-third interest in the Old Home placer mine, near Yankee hill.——C. F. Lukens has bought a sixth interest in the Belcher, Daisy, John W, East and West Ledge quartz mines and the Belcher millsite, near Carters.

A. C. Johnson of Carters has bought the Jacoba one-sixth interest in the El Oro quartz mine, 2 miles south of Carters on Long Gulch mountain.——The Gladys G. M. & M. Co. has bought the Clare D, Jean G and the Bride quartz mines, also the Fanny S, Isabelle and Lulu B quartz mines.

W. S. O'Brien has bought the Curley interest in the Niagara quartz claim, 5 miles north of Groveland. —— H. J. Hughes, J. Barry and E. Sharp have a bond for a deed to the Josephine quartz mine, northwest of the Jones mine and south of the Brown Bird, near Sonora.

G. Williams will resume operations on the Christmas-Berrybush mine on Bald mountain, near Columbia.

At the Telegraph Hill mine, near the Dambacher ranch, a new boiler and hoist have been set up.

YUBA COUNTY.

The Pennsylvania mine at Brown's Valley has been closed down and the machinery on the property is being sold, including a $50,000 electric plant.

At the Pennsylvania mine at Brown's valley, 12 miles east of Marysville, on the 2nd inst., while J. Dean and G. W. Richards, miners, were on the truck in the shaft with the pump at the 1400-foot level the cable parted and the car dropped 100 feet down the incline. Dean rolled off and escaped, but Richards was killed.

COLORADO.

BOULDER COUNTY.

The Dirigo group of mines of six claims in Hawk Eye district, 8 miles from Black Hawk, has been sold to L. D. Godshall of Denver, and final payment made this week. The price is reported at $22,500. Extensive development work is planned. Milling ore has been opened up. The Moffat railroad will pass within 2½ miles of the group. It is intended to thoroughly develop the property before an attempt will be made to treat the ore.

CLEAR CREEK COUNTY.

The Chicago Mountain M. Co. has bought the Black Swan tunnel, the R. B. Hayes and other patented claims 1½ mile from Idaho Springs, on Chicago creek, which they will consolidate with their other claims. The tunnel is being cleaned out and the new track laid, preparatory to driving ahead to develop the Chicago mountain veins, says the Times. The tunnel runs in on the Black Swan vein. —— It is reported that local parties will take over the East Hukill claim in Hukill guich, who will put on a steam plant and continue to sink the shaft. The property is owned by the Haggerty estate at Coalport, Pa.——Anderson, Tanner & Carlson have bought the steam hoisting plant on the Crockett mine, near the Stanley, and it will be put on the Beacon of the West, near Russell guich, which they are operating under lease and bond. —— The New Century mine in Hukill gulch has its steam plant in operation and has begun sinking the shaft.

CUSTER COUNTY.

W. D. Murphy, who closed down the Vanderbilt mine last week, has transferred his miners to another group near Silver Cliff and adjoining the Silver Bar mine.——It is stated the Valley M. Co. will build an ore-treating plant near its mines. President Magamen says they have decided to increase development work.

The Vanderbilt mine, near Querida, has been shut down. It was being operated under bond and lease by D. W. Murphy of Kansas.

Mining operations on the American Flag mine, owned by the American Flag G. M. & M. Co. of Pueblo, near the Bassick mine near Silver Cliff, will be increased. The shaft will be sunk from the 150-foot level. H. Fugel is president.

The Bassick G M. Co., near Silver Cliff, has decided to deepen the main shaft to the 1800-foot level, extending it 200 feet. Arrangements are being made with the Canon City Electric Power Co. for running their hoist with electric power, says Superintendent W. H. Anderson, of Aspen.——The Little Bernice group resumed work this week after a temporary idleness. The company is driving a drift and the cutting of a good shoot at the 280-foot level is expected next week. A quantity of medium-grade ore is being sacked daily from the Louella mine by Thomas & Lawrence. The Blackburn claims are being developed by Smith & Knight.

FREMONT COUNTY.

The Purity Coal & Oil Co. of Denver men has made arrangements for starting a shaft for coal development adjoining the Rockvale coal mine, south of Florence. The company has decided not to sink any oil wells on its coal ground until later.

The Union Oil Co. is arranging to drill for oil near Florence. Leased from the United and other oil companies they have 560 acres of unexplored territory. Of this 480 acres are on the north and 80 acres on the south side of the Arkansas river, says President L. F. Collins. The United Oil Co. is doing considerable work preparing for an increased oil production from the south end of the field. The lines that are used in conveying the oil from the wells to the refinery are being enlarged.

GILPIN COUNTY.

C. Duffield of Denver has resumed operations on the Baltimore tunnel in Gamble gulch, near Rollinsville, and owned by Maryland parties. —— D. C. Earl has a lease on the Perigo mill, and will run it on ores from the Perigo workings. It has not been running steadily on account of the wet condition of the Perigo workings.——Iowa parties are interested in the Blue Grass M. & M. Co., operating the Lone Star, Champion and Tenderfoot group in Phœnix district. They are continuing developments on the Lone Star and Tenderfoot claims and are opening up ore. It is intention of company to build a mill of twenty-five tons daily capacity, either on South Beaver or South Boulder creeks.——It is reported the Mountain Chief mine on Tip Top will be reopened. The shaft will be unwatered and sunk 100 feet deeper.

The Cadillac M. & M. Co., in which Canon City, Colo., and Cadillac, Mich., parties are interested, has taken a lease and bond on the New Hampshire group of claims, near the head of Lump guich, near Rollinsville.——T. Tregay has resumed work on his Honest Boy claim up Lump gulch.

The Evergreen mine, near Apex, has been sold to W. R. McCormick of Denver for $25,000. The tunnel will be driven ahead. The Evergreen ore carries copper and silver, with small values in gold.

GUNNISON COUNTY.

(Special Correspondence).—Excitement still runs high at Nugget City, near Gunnison, where the gold strike is reported. A large number of men are going into the new field.

Gunnison, Aug. 1.

(Special Correspondence).—At the property located by J. C. Bowerman, 3½ miles from Pitkin, the workings are filled up and guarded. Bowerman reports very high assays. They are starting a tunnel to cut the vein 256 feet below the surface. It is stated their reason for not working the property at the shaft is on account of people packing away their specimens and rich ore, and they decided to cover it up until they can build a shaft house. It is believed by many that some one will make a good find, as there are a large number of prospectors in the camp. The nature of the rock where the strike was made is porphyry and quartz.

Camp Bowerman, Aug 3.

HINSDALE COUNTY.

(Special Correspondence).—The Henson creek lead mines, 3 miles west of Capital City, made a short run with their new mill last week and closed down temporarily. It may be necessary to make some changes in the mill before they will be able to run.

The Hanna M. & M. Co. are overhauling their mill and putting in additional machinery. They will install zinc separators and concentrators. The mill when completed will have a capacity of 100 tons per day.

Capital City, Aug. 1.

(Special Correspondence).—The Ute & Ulay Co. have their shaft down 420 feet and drifting for the vein. If the vein proves satisfactory, it is the intention of the company to build a mill. J. Duffy is superintendent.

The California Con. M. & M. Co. have struck a 3-foot vein, the ore shoot averaging 2½ feet in width. The main tunnel is in 600 feet. They have eight claims, including mill-site. A mill will be built this fall. The company will put in a larger compressor and additional drills. The group is on Henson creek, 3½ miles from Lake City. They are working nine men at present. W. Krudup, vice-president of the company, is superintending the work on the mine.

Henson, Aug. 1.

(Special Correspondence).—The Isolde mine, in Burrows Park, has struck another vein of ore, which runs $300 in gold per ton.

The Tobasco G. M. & M. Co., closed down for some time, has again started operations. There are twenty-five men at work and this number will be increased. They have about 5000 tons of ore on hand. O. W. Pierce is manager.

Lake City, Aug. 2.

LAKE COUNTY.

The tonnage for July of the mines of Leadville camp varied little from that of June, being 60,000 tons. Of this amount the Arkansas Valley plant and other trust plants took 60,000 tons, while 20,000 tons went to the Salida smelter and the zinc plants. All of the large producers are under contract.

The machinery for shaft No. 1 of the Gilt Edge mine, which adjoins the A. Y. and Minnie in California gulch, at Leadville, is in place and the work of connecting it with No. 2 shaft started. The latter is down 500 feet, and when the drift from the bottom reaches under No. 1 an upraise of 150 feet will be made.

The Fitzhugh shaft of the Elkhorn M. Co. of London, England, and in Big Evans gulch, near Leadville, has been leased to R. Estey and T. D. Kyle. The mine is supplied with a plant of machinery.

The long drift which will connect the ore bodies of the Midas and the Coronado mines at Leadville was completed last week and is 900 feet in length. The Midas has upraised to make connections with the drift, striking it at 100 feet above the present workings, says the Chronicle. The Coronado has repaired the damage done by the recent fire and are pushing development work, besides shipping 100 tons a day.

It is reported the Dolly B group in Big Evans gulch, at Leadville, will resume operations this month. P. K. Connolly is manager.

LA PLATA COUNTY.

The Eureka & Bulldozer mines, near Durango, having joint workings, have resumed under new management, and a double-compartment shaft started, from which drifting will be begun at 50 and 100-foot levels, and ore extracted from present workings.——The Comstock, Columbus, Cumberland and Bessie G. properties are idle, but it is expected operations will be resumed this season.——The Providence Co. is operating the Wilkinson group with three shifts and has begun to ship regularly.——The Durango Girl mine has been taken over by the new management, the Hazard Co., which bought it recently. They will put on more men and increase development.

SAN JUAN COUNTY.

J. H. Pape of Colorado Springs, manager of the Ledge M. Co. at Silverton, reports operations going ahead and seventy men are at work. The 200-ton concentrating mill is handling 100 tons per day, but will be run up to its full capacity, as preparations are being made to break down 200 tons a day. The Ledge is located 1½ mile from the Yankee Girl and Guston and said to be the same vein system. It is equipped with shaft house and hoist good for 1500 feet.

TELLER COUNTY.

C. Boll, who has a lease on the Molly Kathleen mine, above the El Paso Gold King at Cripple Creek, will put up a 100-ton cyanide mill below the dump on the west side of the shaft. In the second level the ore shoot has been broken into for a distance of 25 feet. This ore assays one ounce in gold. The ore body lies between basalt and andesite. On the 700-foot level development work is in progress. At this point they have come into the Gold King quartz vein. The cyanide mill will treat both the dump ore and that hoisted from the 200-foot level.

It is stated that the Mary McKinney M. Co. resumed work this week, and 100 men will be employed. The mine has been shut down three weeks owing to changes to the shafthouse, and in addition the company has been putting in ore washing machinery. The Mary McKinney has increased the capacity of its ore bins to 250 tons.

The work of remodeling the Beatty plant, near Cripple Creek, is reported completed. Stevekin & Zimmerman announce that they will soon be ready to receive ore. The mill has been converted into a cyanide plant and will treat the dumps of the Golden Cycle and Lillie mines.

The Key West G. M. Co. has given a lease to P. Gortner et al. on its Con. Virginia claim on Carbonate hill, near Cripple Creek. It has a shaft 50 feet in depth, which will be used by the lessees.

The directors of the Banner G. M. Co. last week granted a lease to Wilder & Crummer on the middle block of the Fountain Valley claim of the company, near Cripple Creek, at 20% flat royalties. The lessees will use the Fountain Valley shaft, which is down 145 feet, and from this point will do exploratory work.

Of the 255 blocks into which the Cripple Creek holdings of the Stratton estate have been divided for leasing purposes, three more were let last week to parties who start developments this week. So far, the directors have leased twenty blocks of ground, all in Poverty gulch, leaving 145 blocks in that section and ninety on Bull Hill yet to be let out. The above mentioned three are: J. Simpson of Cripple Creek on block 12, a portion of the Nada claim; C. Butler of Cripple Creek on blocks 99 and 100 of the same claim; and the third to J. Grannis of Colorado Springs on block 135, embracing the Baby McKee claim in Poverty guich. On each of these the lessee is required to do heavy sinking and other development work. W. Lloyd, secretary of the Stratton Cripple Creek M. & Dev. Co., says it is intended to lease all of the Poverty gulch holdings before leasing the Bull hill estate.

F. J. Campbell, manager of the Vindicator Con. G. M. Co., in his report covering the operations of the company for the first six months of 1903, shows: Smelting ore, a gross production of 4,991 tons, yielded an assay value of $258,667; freight and treatment charges were $49,734.59. The gross production of milling ore was 3,057 tons, which yielded an assay value of $49,135.58; freight and treatment charges, $21,997.55. The combined tonnage was 8,048 tons, that yielded a total assay value of $307,913.19 and net proceeds of $236,081.05. The production came from three shafts, as follows: Smelting grade—Shaft No. 1, net tons, 4,016; Shaft No. 7, net tons, 953; Shaft No. 11, net tons, 20. Milling grade — Shaft No. 1, net tons, 2,394; Shaft No. 7, net tons, 297; Shaft No. 11, net tons, 365. The total operating expenses of the mine were $113,364 31; the general expenses, $6,509.35. Of the production of $307,813.19 the lessees shipped ore amounting to $36,218 98.

The State Investment Co. of Denver, H. A. McIntyre president, will lease out all of its holdings in Cripple Creek district at royalties of from 5% to 20%. There are twelve claims for lease, and not all contiguous.

The Mineral Hill Railway & Tunnel Co. has been organized at Cripple Creek, with D. F. Blackmer president and manager and L. C. Moore secretary and treasurer, and they propose to drive a tunnel into the hill for 3000 feet. The tunnel has been started on the west side of Mineral hill on the Favorite fraction, and is in 190 feet. The management expects to eventually cut the granite contact, which traverses the hill at a depth from the surface of 800 feet.

McLeod & Eshy have a lease on the surface workings of the Unexpected mine, near Windy Point, adjoining the War Eagles mine, at Cripple Creek, and will build a cyanide mill of fifty tons daily capacity. They propose to use a ¼-inch mesh.

IDAHO.

BLAINE COUNTY.

The Idaho Mines Con. Co. resumed operations at its Red Cloud group of mines, near Hailey, this week, says I. E. Rockwell, manager.

BOISE COUNTY.

The Lincoln mine, in Pearl district, of which J. T. Hodson of Salt Lake City, Utah, is manager, will be equipped with electric power, the wires for which are being strung. Heretofore the plant has been operated by gasoline engines, says the News.

CUSTER COUNTY.

The Loon Creek G. M. Co., near Custer, has bought the Black Queen group of three claims, a gold-copper property, on Canyon creek. The ledge is said to be 7 feet wide and the croppings average $6 in gold. Manager Eddy of the Loon Creek G. M. Co. put men to work on the group this week.

ELMORE COUNTY.

J. L. Weaver, who is putting in a dredger near Glenn's Ferry for taking out Snake river gold, says he will begin operations this week.

S. J. Baldwin of Boise has a bond on the Pearl group in Dixie district for himself, E. S. Leaver and D. Stauffer of Salt Lake City, Utah. This group includes seven claims and a fraction adjoining the Gold Ring group on a parallel ledge. It is intended to start development work next week.

IDAHO COUNTY.

The Lucky Lad Co., operating in Buffalo Hump district, near Hump, has decided to put in a 2-stamp mill, with gasoline power for the winter, to test the property, which is being worked by a shaft, now down 50 feet. A crosscut on the vein shows 20 feet of ore of good grade. The company expects to go down 200 feet this winter, hoisting machinery being on the ground to sink to this depth. The mill will be run on the rock taken out in development work.

The Jumbo mill, near Roosevelt, will be ready to run next week.

LEMHI COUNTY.

C. Wright, manager of the Haidee mine, near Salmon, reports the tunnel going ahead at rate of 4 feet per day.——R. L. and R. M. Edwards, D. Kane and J. H. Hodgson have a bond on the Shoo Fly mine and have started to clean out the shaft and begin development. —— The Gold Ridge M. Co. has bought the Kane & Ramey quartz and placer property on Silver creek and has put men at work.

SHOSHONE COUNTY.

C. S. Crysler, principal owner of the three gold dredgers, the Mascot, Delta and Northern, near Delta, operating on Beaver and Trail creeks, has sold all his interest in the Northern dredger to Eastern men, but retains the control of the Delta and Mascot. He has bought the placer ground on Potosi gulch where it empties into Trail creek, near Delta. Crysler and Eastern men are preparing to start development work on the Wake-up-Jim group of claims on the divide between Delta and Murray, says the Spokesman-Review.

MICHIGAN.

HOUGHTON COUNTY.

The annual report of the Wolverine M. Co., near Kearsarge, for the year ended June 30, 1903, with comparisons, is as follows:

	1903.	1902
Mineral product, lbs.	11,330,370	6,232,800
Refined copper, lbs.	8,260,386	4,984,367
Proceeds of copper	$1,030,756	$ 658,602
Interest	2,504	6,730
Total receipts	$1,033,260	$ 665,332
Expenses	548,923	424,330
Mining profit	$ 484,337	$ 241,002
Construction	38,014	264,688
Net profit	$ 446,323	$ 23,686
Prev. surplus	276,467	540,153
Total surplus	$ 722,790	$ 516,467

The Centennial Co., near Calumet, has removed the old shaft house at the "A" shaft on the Kearsarge lode and has started building a larger shaft house there.

The Champion Copper Co. has let a contract for a water works system for their Painesdale Champion mine location. A tank holding 200,000 gallons will be located on a tower 75 feet high, back of the town, with a pumping station at Lake Serrault. The automatic stokers in use in the Champion mill, in connection with the fuel economizer, are reported showing a saving of 10%. Four men—two on each side—handle the battery of five boilers, three only being in steam since the compounding of the heads. The Champion has reduced the amount of water used to the ton of rock stamped from thirty-five tons to twenty-six tons, making 3,100,000 gallons to 500 tons of rock, the daily capacity of each head.

The report that the Calumet & Hecla Co. at Calumet will start production from the Osceola lode shafts this year is said by the management to be incorrect. Work on this lode will not start until the entire mill has been transformed to electric power to correspond with the six new heads—a matter of at least five years.

The new shaft at the Winona mine, at Winona, is 8 feet in the ledge, which is giving good copper indications.

KEWEENAW COUNTY.

The Mohawk mine, near Allouez, is reported producing at the rate of 7,000,000 pounds of copper per annum and that this copper is costing them about 9 cents per pound.

The new shaft at the Ahmeek mine, west of the Mohawk, near Allouez, is down 36 feet to near the ledge. Trouble has been experienced with sand, and two additional drainage shafts are being sunk. The hoist from the Centennial is on the ground and an eight-drill compressor from the Trimountain has been received.

ONTONAGON COUNTY.

The site of the smelter of the Michigan Smelter Co., owned by the Copper Range Co., operating near Rockland, has been cleared and railroad tracks are being laid for the delivery of material. The smelter company has experienced considerable difficulty due to the scarcity of unskilled labor, says the News.

MISSOURI.

GREENE COUNTY.

At Springfield it is expected a branch oxide plant of the New Jersey Zinc Co. will be established, says the News-Herald.

JASPER COUNTY.

Superintendent J. H. Stephens of the Granby Co. reports a new strike in Snake hollow on the company's tract at Joplin. Rawley, Muncie & Co. are sinking a shaft and they struck lead at 60 feet and jack at 80 feet. New Mexico parties have begun drilling in Leadville hollow on the Granby lease.

Q. Yates, J. Cragg, B. Herron et al. are sinking a prospect shaft in the Kansas City bottoms in the Consolidated M. Co. ground near the Watkins-Baird mine, near Joplin. B. Herron is superintendent.

J. W. Ellis, T. Leggitt, J. B. Gibson and D. Pool have drilled through 20 feet of ore on their lease 2½ miles southeast of Webb City.——J. Luke's Holy Smoke mine turned out 112 tons of ore last week, clearing $2500.

B. M. Stevens is moving the Boston-Cherokee mill to the Mulberry mine at Duenweg.

The American-Cornfield Zinc Co. at Carterville has moved its plant from the New Century mine to the Myrtle D., where forty tons of jack and twenty-five tons of lead are produced each week, says the Herald.

One hin of zinc ore from the mine of Power & Co., on the Empire reserve, near Joplin, brought $41 per ton last week, says the Joplin News-Herald. It graded up to 64.5% zinc.

LAWRENCE COUNTY.

A good body of zinc silicate was struck last week at 100 feet in the drill hole being put down on the U. Z. land, near Aurora.

Jones & Co. have a lease on the Good Luck land, east of Aurora and north of the Frisco tract, and on which a shaft has been started.

NEWTON COUNTY.

Woodcock & Sons have bought the Cannonball mine at Granby and shut down the Rheumania. They will start work on the Cannonball this week.

SHANNON COUNTY.

The National L. S. & M. Co. was incorporated last week at Springfield by O. W. & O. D. Fisher, H. & S. A. Cordz, H. P. Thomas, F. L. Eddy, B. Heer, M. Paulsen and W. J. Orr, to operate near Birch Tree.

STONE COUNTY.

At Galena Downing & Co. are making regular shipments from one of the Mossback claims.

Boughton Bros. & Beckwith, at the Victoria mill, are running tailings and report good returns.

Greenfield, Day, Graffe & Co. are taking out 150 tons of zinc ore a week that will average $2 per ton.

Wheeler, Hallam & Hillhouse, on the Mossback lots, are sinking a shaft and will start shipments next week.

The Roena M. Co. has leased the Bonesteel mill, which it will start up next week.

Board, Messenger & Sanders have repaired the Overleigh mill, on the Schermerhorn land, and are making two tons of ore a shift from the tailings.

R. Ping has leased Scott & Co.'s mill and will start up next week. He also bought the Dwight mill on the New York Zinc Co.'s ground.

H. Bates and T. Teborr have leased the Commercial mill on the L. D. Phillips land, and are running the Dansingburg tailings.

W. J. Wilkes has put another set of 30-inch rolls in the Monte Cristo mill at Galena, and is running the Woodpecker tailings.

On the Boice & Milliken farm, 3 miles southwest of Galena, both lead and zinc ore were struck at a depth of 100 feet in the drill hole by A. Brown of Socorro, N. M., who will sink a shaft.

Jeffiers, Webster & Ping have leased the Manhot mill on the Wyandotte land, near Galena, and will expect to make twenty-five tons of zinc per week when they get the mill repaired. The ore assays 50% zinc and no iron or lead.——C. Foster, A. and D. Elder and C. Day have taken one of the old prospects on the New York Zinc Co. ground and took out thirty tons of zinc and 14,000 pounds of lead last week. They are working at depth of 65 feet.

MONTANA.

BEAVERHEAD COUNTY.

At the Birch creek smelter of the Western M. Co., operating the Indian Queen mine near Dillon, Superintendent G. H. Hiberlein reports operations continue full blast. The plant is not large enough to treat all the ore, having a capacity of thirty-three tons per day, and they propose to increase the capacity to 150 tons per day, work on which will begin by Sept. 1st.

At the Indian Queen, in the main tunnel 350 feet from the opening, a raise of 180 feet has been made in ore, and at that height a cross tunnel run connecting with the surface shaft. A winze is being sunk from the same place in the tunnel to the 150-foot level. At the station a 6 H. P. gasoline engine runs the hoist and a small pump. T. Ellis is superintendent of the mine. The Western M. Co. is also sinking on the Snowball claim.

Superintendent Stanchfield of the Ajax mine, near Dillon, says the vein opened up is showing 7 feet wide and assays $7 in gold, forty ounces silver, with 8% lead. Drifting in tunnels Nos. 2 and 3 is going ahead. It is expected the company will build a tramway, power plant and mill, work to begin next month.

BROADWATER COUNTY.

Roseberg & Sutton of Helena are pushing work on their concentrator at the Stray Horse mine, at Winston, and expect to have it running by Sept. 1.

CARBON COUNTY.

The property of the Rocky Fork Coal Co., near Red Lodge, is to be sold Sept. 1 to the Northwestern Improvement Co., which owns and operates the coal properties of the Northern Pacific Railroad Co. This company has six mines in Montana and Washington, producing 2,500,000 tons of coal a year.

FERGUS COUNTY.

At the Barnes-King mine, near Kendall, last week, the north drift from the 200-foot level opened into ore, the whole face of the drift averaging $12 per ton in gold. It is the intention of the Barnes-King Co. to drive the tunnel north from the 200-foot level, a distance of 4000 feet, to the Dog creek part of their property where another ore body is opened up. The tunnel will come out near the surface at the north end, and ore from the north end claims will be hauled via this route for treatment in the company's mill, says the Kendall Chronicle. Additional drills have been put in operation in the north tunnel, says Manager E. W. King, and he has eighty-five men on the pay roll.

Work was resumed last week in sinking the shaft at the Abbey mine, near Kendall, and will go to depth of 400 feet. E. Johnson is superintendent.

JEFFERSON COUNTY.

A strike of high-grade silver ore is reported made last week in the Liverpool mine at Lump gulch, near Clancey. The company has sunk the shaft from the 400-foot point to 750 feet with crosscuts at the 500, 600 and 750-foot levels, and in each of these has found ore, the vein being 6 feet wide at the 500-foot level with a 1-foot pay streak. The Liverpool Co. is composed of Eastern men.

The Boulder-Comstock mine, 1½ miles from Basin, has been bonded to A. S. Ray & Co. of Butte, who have started development work. A hoisting plant will be put in and the shaft sunk 200-feet from the 280-foot level. The ore carries silver and copper. Water level has not been reached.

The Dunstan mine at Elkhorn has been bonded by C. Hopkins, who will develop it thoroughly. Parties are negotiating for a bond on the Relief mine at Elkhorn. The Elkhorn Queen, Holter and Paymaster mines are being worked.

The Jacquemin-Rothfus mines near Elkhorn have been sold to the Pittsburg-Montana M. Co. for $25,000. There are three claims in the group.

After a shut down of three years work is again under way on the Eva May mine near Basin. The ore shows gold, silver and copper.

Manager Hewitt has let a contract for another 1000 feet of tunnel in the Bullion mine of the Cataract M. Co., near Basin. All of the tunnel will be planked.

LEWIS AND CLARKE COUNTY.

The Capital M. Co. of Helena is taking out high-grade gold ore from the Faith mine, in Holmes' gulch, 3 miles from Helena, and shipments have begun.

Hardgrove & Cary report opening up a promising iron lead at the head of Nelson gulch, 5 miles from Helena.——The Royal Potosi M. Co. of Butte has started work on its properties in Potosi district, which have been idle for some time.

Austin Bros. have bonded the Strawberry group, near Marysville, in Skelly gulch.——The New Boston M. Co., composed of Dakota men, has been incorporated to work a group of mines at Corbin, near Helena.

PARK COUNTY.

Work is going ahead in the Kimberly-Montana mines at Jardine. The 40-stamp mill on the Revenue mine, one of their group, is running steadily and the tailings are cyanided. The new 40-stamp mill will be running by Aug. 15, says the Inter-Mountain.

SILVER BOW COUNTY.

Work is progressing at the site of the Pittsburg & Montana C. Co. smelter being built in East Butte. Five cars of steel arrived last week. The foundations for the two 400-ton furnaces are completed and the erection of the steel frame work of the smelter has begun. Development work continues in the Farrel shaft of the company. While crosscutting the lead on the 1200-foot station a body of ore running 8% in copper, which is the same class of ore as was struck on the 800-foot level, was opened into.

NEVADA.

DOUGLAS COUNTY.

The Longfellow G. M. & M. Co. has incorporated to operate near Gardnerville by E. W. & M. E. Carman and F. Everett.

ESMERALDA COUNTY.

Superintendent Colcord of the Con. Esmeralda M. Co., 12 miles from Hawthorne, says he is making preparations to build a 40-stamp mill on their group, and it is expected to have the mill running by January. About 230,000 feet of lumber will be used.

L. L. Patrick & Co. last week made the first payment on the group which they have bought in the Tokop district, 55 miles south and west of Tonopah. Work will begin next week and the group developed. Later a mill will be put up.

EUREKA COUNTY.

Manager P. Porter last week made first payment on the Keystone group of mines near Eureka, for Chicago men, and has started development work. In the main ledge, a contact between the limestone and granite, he has opened up a body of copper-bearing ore.

LINCOLN COUNTY.

A. J. McQuaid, of Pueblo, Colo., having the Good Enough and the Rajah mines, near Searchlight, under bond, says he will increase development work. The Good Enough is the northeast extension of the Searchlight mine. The Rajah lies between the Southern Nevada mill and the Blossom mine.

M. G. Banks, superintendent of the New Era mine near Searchlight, says 6000 feet of water pipe have arrived, which will be used to pipe water to the mill which will be built.

In Newberry district, near Searchlight, the Chiquita group and the Juniper group have been bonded to the Providence Exploration & Development Co. of Providence, R. I., for $35,000 and first payment made. The Juniper group of five claims is 6 miles south of Spirit mountain, in the Newberry range. The pay shoot in the ledge is 3½ feet wide, averaging $15. A 2-stamp mill has been run on the property for several years. The development work on the Juniper consists of 650 feet of shafts and drifts in the ore body. The Chiquita group lies 4½ miles west of the Juniper and has 800 feet of workings.

LYON COUNTY.

Reports from Como indicate a revival of mining operations in that camp. The

Comc-Eureka mine and mill are in full operatinn under Manager J. H. Rae and thirty tons of ore are being crushed daily. Electric powor for operating and lighting the mine and mill is transmitted from the company's plant at Dayton, which has a reserve of 1100 H. P. if required. The company employs twenty men ——Work was rcsumed in the North Rapidan tunnel this week.

NYE COUNTY.

The suit against the Tonopah M. Co. by the Tonopah & Salt Lake M. Co for the possession of portions of the Butler group of mines was decided on the 3rd inst. In the United States Circuit Court at Carson in favor of defendant. The suit was brought on an adverse claim and a protest entered in the United States land office at Carson against the application of Butler's company for patent to consolidated claims embracing eight locations, complainants alleging that two of Butler's claims, the Valley View and the Silver Top, overlapped three of their locations. On August 30, 1900, Butler put up his location notices and on March 20, 1901, the company filed in the land office at Carson an amended notice of location, embracing eight consolidated claims. But the Tonopah & Salt Lake Co. had staked its claims so that in part they were coincident with the ground staked out in the amended notice of the Tonopah M. Co. The main plea of the complainant was that in several instances Butler's boundary stakes were not to be found, and also that his amended notice varied from that first placed by him. To this argument Judge Hawley gave the following answer: "When a valid location of a mining claim is once made it vests in the locator and his successors in interest the right of possession thereto, which right cannot be divested by the obligation or removal, without the fault of the locator or his successors in interest, of the stakes and monuments marking its boundaries, or of the obliteration or removal from the claim of the location not'ces posted thereon. The right of the original locators to change their original location, so long as such change does not interfere with the existing rights of others acquired previous to such change, is unquestioned. The amended certificate of location, when made, becomes the completed location of the discoverer, and is just as valid as if it had been made in the first instance."

C. Peters reports preparing to put in a mill of 10-ton capacity to work the high-grade ore from his mine at Ellsworth, 10 miles west of Berlin. The shaft is down 50 feet and a ledge 2 feet wide carrying $100 a ton in gold has been opened up.

The foundation for the mill to be built on the King Tonopah ground, near Tonopah, will be finished this week. They have fourteen men employed.

Diamond drill operations in the Mizpah mine at Tonopah are progressing and the hore will be driven to depth of 1500 feet below the 700 foot station.

NEW MEXICO.

GRANT COUNTY.

W. C. Chandler, who is reopening the Mountain Key mine at Pinos Altos, reports having struck a vein of gold ore which is 4 feet wide. This mine is 700 feet deep. Chandler is getting out some ore for shipment, the second grade of which he is concentrating.

The Shamrock M. & M. Co., operating at Pinos Altos, has taken a lease on the Pacific mine, owned by the Hearst estate, and has men at work. The ore from this mine is nearly all sulphides and the company is using it for fluxing purposes at its smelter.

The American Con. C. Co. will put up a reduction plant on its group in Shakespeare district, south of Lordsburg, says Manager A. R. Gibson This plant will be operated in addition to the concentrator already on the group. Gibson has also made arrangements for development by his other two companies—the Gibson Dev. Co. and the Shaw-Gibson M. Co.

LINCOLN COUNTY.

The Cashier M. Co. of Denver, Colo., operating at Anchor, has decided to run 1500 feet more of tunnel. The vein is of free milling ore running $3 per ton. A. W. Schmidt of Antonito, Colo, is manager.

OTERO COUNTY.

The Alamo M. & Dev. Co. has incorporated at Alamogordo, with M. P. Coakley, W. C. Hood, W. K. Shelton and T. T. Leask, and W. Irish of Iowa.

SAN MIGUEL COUNTY.

Superintendent Fritze of the Torpedo mine last week lowered the new pump down the Anderson shaft and is unwatering the lower levels.

At the Gold Camp, near Rio Grande, a strike is reported in the Alligator tunnel, owned by the Dora M. Co., on the eastern slope of Mineral hill, showing a 3-foot vein of ore, 2 feet of which are galena-bearing quartz The ore runs 45% lead, 22 ounces in silver and $5 per ton in gold. The tunnel is in 150 feet and this ore body was found 125 feet from the surface.

SIERRA COUNTY.

Development work on the Richmond mine, near Hillsboro, is progressing, and in the 200-foot level a shoot of shipping ore 4 feet wide has been opened up. The Richmond is owned by Boston, Mass., men, who propose to sink a double-compartment shaft to depth of 1000 feet, blocking out sufficient ore to justify the erection of a mill or smelting plant.—— At the Happy Jack mine work is progressing. They expect to start the Andrews mill next week ——The Hillsboro G. M. & M. Co.'s mill will be ready to start up this week. The pipe line from the water right to the mill is completed. An additional table has been placed in the mill, says Superintendent Kasser. In the 200-foot level of the Little Ready Pay there are 4 fect of ore that will average $30 to the ton ——The Empire Co. report that mine will put down their working shaft 500 feet before starting to run any levels.

Manager Winspear and A. J. Hirsch report work started on putting up a mill and all necessary steam power equipment for the mines of the South Percha G. M. & M. Co., near Hillsboro. They also have a whim, which will be put up on the Kingston, one of their mines. The company expects to have the 20-ton mill ready for operation by October 1.

The Minnehaha mill will start up by September 10. The difficulty in securing the needed supply of lumber has been a drawback. Work on the Minnehaha mine has been suspended temporarily and operations concentrated on the Great Republic. J. L. Terry is superintendent.

SOCORRO COUNTY.

(Special Correspondence) — The 20-stamp mill recently erected by the Socorro G. M. Co. upon its properties west of Magdalena will be in operation in a few days. This property has been developed the past year under the superintendence of C. L. Herrick of the University Geological Survey, and consists of fourteen claims, covering several miles of quartz veins in andesite, which forms both walls. The veins vary from 4 to 12 feet in width and have been explored 125 feet below the water level, with the result of uncovering more uniform ore at the greater depths. The ore is oxidized and free milling, and, though low grade, exists in large quantity and over a large area The mill will be fully equipped for concentration below the plates.

Magdalena, July 30.

NORTH CAROLINA.

UNION COUNTY.

Manager G. S. Peyton, operating the mines and mill of the Colossus M. Co. at Waxhaw, says the production of gold from the cyanide plant has started the bullion going to a refinery in Chicago, Ill. E. Gayford is in charge of the plant at the Colossus and reports raising the saving from 84% to 92%. The ore body is 400 feet between walls, showing an average of $4 per ton, the cost to mill it being 85 cents.

OREGON.

BAKER COUNTY.

J. Fawcett of Omaha, Neb., president and managing owner of the Psyche M. Co., near Sumpter, says the company is making preparations to put in a hoist with depth capacity of 500 feet, together with pumps and other machinery. Ten stamps of the twenty are dropping, says Superintendent Elmer.

At the Eureka and Excelsior mines at Bourne, owned by J. Bourne, Jr., Superintendent J. S. Wyatt says operations were resumed this week.

GRANT COUNTY.

E. S. Topping and W. E. Sanders, who have a bond on the Oreole claim, near Susanville, started work last week. The Oreole is said to carry telluride.

Work was resumed at the Copperopolis mine, in Quartzburg district, last week, after a temporary idleness, says W. W. Gibbs, managing director. He will add another drill to the compressor plant and increase development work. In the main tunnel there is cobalt in the ore, besides values in gold, silver and copper.

The Jupiter G. M. Co., operating the Prairie Diggings mine, near Prairie City, is preparing to put in machinery, including a pump and hoist, with working capacity at depth of 600 feet, says Manager Messner. The shaft is double-compartment.

J. F. Watson, of Portland, says operations are to be resumed on the Keystone mine in Quartzburg district. A hoisting plant and other machinery are being put in. It is intended to do deep sinking work before putting in a mill.

JACKSON COUNTY.

The Jacksonville Times says during the past year a total of 350 mining claims were located in Jackson county.

JOSEPHINE COUNTY.

Work is progressing at the Granite Hill mines, near Grant's Pass, and the 10-stamp mill is expected to be in operation early in September. Development work has been carried on steadily. Improvements in the equipment of the Granite Hill placers are also in contemplation, among them a hydraulic elevator on the lower part of the ground.

SOUTH DAKOTA.

LAWRENCE COUNTY.

The Gilt Edge and Dakota Maid mines of Bear Butte district, near Galena, have been bought by Eastern and local parties for $150,000, and the Gilt Edge - Maid G. M. Co. formed, officered as follows: J. L. Turner, Springfield, S. D; W. Lardner, W. Selbie, J. R. Wilson and G. A. Duncan of Deadwood, with W. D. Lowry, Minneapolis, Minn. G. A. Duncan of Deadwood is manager. The company will build a cyanide plant having an initial capacity of 125 tons a day. The ore is said to average $7 per ton. The two groups of claims comprise 132 acres of mineral land along Strawberry gulch.

The reduction plants in course of construction and proposed will increase the Black Hills gold out ut within the next six months as follows, says the Record: The Hidden Fortune G. M. Co. will mill 300 tons daily; the Columbus Con. G. M. Co., 1000 tons daily; the Golden Crest M. Co., 100 tons daily; the Reliance G. M. Co., 300 tons daily; the Dakota Maid-Gilt Edge Co., 300 tons daily; the Horseshoe M. Co, 500 tons daily; the Dorr - Lundberg - Wilson Co., 100 tons daily; the Homestake M. Co., 500 tons daily; the Phœnix G. M. Co., 250 tons daily — a total increase of 3350 tons over the present daily capacity of all the mills of the Black Hills.

The Dizzy M. Co. is prospecting the lower quartzite ore measures on its ground below Maitland by means of a diamond drill, says the Review. This company, organized for operations in Garden City district, has 1100 acres north of the Penobscot group and expects to begin sinking this month.

Men are at work at the Gold Eagle mine, near Maitland, opening up ore bodies. A cyanide mill will be built.

Sinking has been resumed in the Hidden Fortune shaft, near Deadwood, after a shut down of several months, owing to destruction of hoist by fire. The shaft has been unwatered and they are down 300 feet. At that depth a station will be cut and drifts run to explore the Bingham vein. The alterations to the mill are progressing and the company expects to start milling ore by September 15.

The Lead City Call reports that at the Oro Hondo mine, near Lead, work in the three-compartment shaft is progressing and it is down 530 feet. The shaft is in ore and will be continued to the 600-foot level, at which point crosscutting will begin, says Manager Nix.

The Spearfish mill of the Spearfish M. Co., operating in Ragged Top district, near Spearfish, is handling 220 tons a day, all of which is coming from development work, as no stoping is as yet being done. They are driving three breasts, all in ore, in the Black Diamond vein, on the south end of the property. The Kelly cut was run in 110 feet and three laterals driven, which are in 160 feet farther. These drifts are 12 feet wide. The vein is 10 feet in thickness. On the north end of the group a vein has been opened which is 11 feet wide, assaying $7 per ton, the ore body being proved by five shafts.

PENNINGTON COUNTY.

Milling ore is being blocked out in the mine of the Golden West M. Co. at Hornblende camp, near Rochford, which assays $4 50 a ton, of which it is claimed two-thirds can be saved by amalgamation. The company intends to build a mill in the spring to replace the test plant on the ground, and will be of 200 tons daily capacity. The tailings will be cyanided. From the mine to the mill the ore will be transported by aerial tramway. J. H. Fisher is superintendent.

UTAH.

IRON COUNTY.

T. E. Stenson has men at work on the Sidewinder mine, near Stateline, sinking a shaft on the ledge. Ore is being opened up showing values in free gold, with a little silver.

At Stateline the Johnny M. Co. has put in an air compressor and will increase development work. It is proposed to later install additional stamps at the mill.—— The Hope group, owned by a Wyoming company, with W. E. Stoddart of Laramie, Wyo, as manager, is getting ready to begin development. A gasoline hoist is being set up and a working shaft will be put down.——The Venus group will be reopened.——A one-fourth interest in the Tribune group has been bought by W. E. Stoddart.

PIUTE COUNTY.

(Special Correspondence).—The Mount Baldy M., M. & P. Co., with holdings above Ten Mile creek, near Marysvale, has been incorporated, with J. Patton, of New York, president, and R. De Witt, general manager. Assays from the Overlooked shaft give returns of $150 in gold, with small percentage of silver. There are five claims in the group. An electric plant is being put in to furnish power to the mill.

The Gold Run M. Co., of Salt Lake City men, has bonded and leased the Wedge group in the Horse Heaven district, F. Dalton, of Salt Lake City, will have charge of the property. Operations were started last week and more men will be put on as fast as development will permit, and the shipping of ore will begin.

The Henry Bradburn M Co., in the Cottonwood district, has men at work and report operations progressing. Two tunnels are being run to crosscut the vein, which is 75 feet wide. H. Bradburn is manager and J. U. Sargent, superintendent.

The Franklin M. Co. has started two tunnels, one on the Cottonwood side and one on the Bullion creek side. Two thousand feet will have to be run for them to meet. It is expected from surface indications a good body of ore will be opened up. O. Larsen is superintendent.

The B. W. & H., in Sevier canyon, sold a shipment of ore last week on controls, showing $17 gold and forty-nine ounces in silver. The ore is from a 3½-foot vein.

The Deer Trail mine is reported sold last week and arrangements are being made to resume operations. With these mines operating and the Treasure Vault, the L. & N., the Alderbaran and the Per Jue Surprise also producing, Marysvale district is again becoming active.

Marysvale, August 3.

The Annie Laurie mine at Marysvale has been closed down temporarily, says Manager C. I. Rader, pending improvements on the mill, which are under way.

SALT LAKE COUNTY.

The Falco group of claims at Bingham, owned by the Cluster M. Co., is to be opened up through a tunnel which was started last fall through the main Bingham canyon, says Superintendent Falco. The first ledge expected to be tapped is the Lead, while at 1100 feet from the mouth the Yosemite vein will be cut. The mouth of the tunnel is on the line of the Copper Belt Railroad.

Manager G. Lavagnino of the Butterfield mines at Bingham says operations will be resumed.

Manager E. W. Young of the Mystic Shrine mine of Bingham has bought the St. Elmo location near Bingham.

UTAH COUNTY.

The Salvator M. Co. has been incorporated to operate the Salvator and the Nevada lode claims in Tintic district, near Eureka; J. Knight, J. Evans, R. E. Allen, A. M. Knight and W. E. Rydalch.

WASATCH COUNTY.

The South Quincy M. Co. has been incorporated at Salt Lake City by A. V. Taylor, J. H. Powers, W. D. Sutton and A. W. Casey. The company holds a bond and lease on twelve claims in Snake Creek district.

WASHINGTON.

FERRY COUNTY.

E. D. Ross, secretary and treasurer of the Magnolia G. & C. M. Co., is making arrangements to start a 200-foot shaft on the Johnson mine on Iron mountain, 8 miles southwest of Northport. This property has 300 feet of tunnel, says the Review.

WISCONSIN.

LA CROSSE COUNTY.

C. Scofield of Brownsville, mining on Wildcat bluff, near La Crosse, reports having found quartz carrying gold.

WYOMING.

CARBON COUNTY.

Near Grand Encampment, the New Rambler mine is going down. The deepest point, 200 feet, is in ore and recent work has shown a second ore shoot. A crosscut was started from the shaft and run 170 feet north; from face of crosscut a winze sunk 50 feet on incline, and from bottom of winze a crosscut run 45 feet, in glance and carbonate ore. The ore in the crosscut is all of milling grade. The winze will go deeper.

FOREIGN.

AFRICA.

RHODESIA.

The Rezende Co, near Bulawayo, July 15, report: Results for the quarter ending June 30: Wet tons milled, 9790; fine gold recovered, 3579 ounces; value of return, £15,210; costs per ton, 18s.

TRANSVAAL.

The East Rand Mining Estates report in Palmietkuil borehole No. 2, reef of hanket (not main reef series) struck at depth of 1800 feet. Boring is being continued, and the hole is now down 2100 feet. The borehole on Grootviei is progressing, and it is expected the reef will be struck within next 850 feet.

WEST AFRICA.

At the Broomassie mines the first installment of machinery for the 40-stamp mill is being set up.

Con. Goldfields of the Ivory Coast, at Bassam, report on Catasso concession shows, in No. 1 west shaft the width of the lode is 8 feet at water level and gold bearing. Manager Woodyatt has driven 40 feet on the lode. In No. 3 east the width of the lode is 4 feet at the water level and gold bearing. The east lode across Mezan river contains free gold.

AUSTRALIA.

WESTERN AUSTRALIA.

The Proprietary Colliery, at Collie, have put in a fan at their mine with a capacity of 85,000 cubic feet of air per minute. The fan is not as yet working at its full capacity, but is giving 400 cubic feet per man per minute for all the men and horses employed in the mine. The fan is driven by a 16 H. P. motor, and the air way is lighted by electricity. The electric pumps in the mine are working satisfactorily, says Manager Evans.

The Kalgoorlie Gold Recovery Co. report 214 tons of concentrates treated at their Orotava works for a yield of 1244 ounces gold. The average was 5.81 ounces per ton.

The reported request of the Council of West Australia Mine Owners to the Government for the appointment of an expert mine inspector for the purpose of checking the reports of ore reserves in the mines of Kalgoorlie district, is denied by the directors of that company.

BRAZIL.

The Brazilian Government at Rio de Janeiro has issued a call for tenders to work the monazite sand placers of the Empire.

BRITISH COLUMBIA.

CASSIAR DISTRICT.

A strike of placer gold is reported near the headwaters of the Stickeen river in Stickeen division.

EAST KOOTENAY DISTRICT.

J. D. McDonald, general superintendent of the West Kootenay Power & Light Co. electrical power plant at Bonnington falls, and T. R. Stockett, Jr., general superintendent of the Crow's Nest Pass Coal Co., Ltd., are making arrangements to put in an electric lighting system for lighting the Morrissey mine buildings, employes' houses and the town of Morrissey. The plant will have a capacity of 3000 lights and he a two-phase alternating system. The engine for running the dynamos is on the ground. Stockett states that eight carloads of wooden stavepipe, from 6 to 12 inches in diameter, are on the ground for the water works line to the town. The ditch for this line, which will be 16,000 feet in length, is being cut. Material for slack coal storage bins at the coke ovens is arriving and work on these will start this week. One million feet of timber will be used in the construction of these bins, which will have a storage capacity of 5000 tons of coal. Additional bins will also be built to contain coal for domestic purposes. Sixty of the 250 coke ovens under construction are ready for filling, which has started, and they will be lighted up for the burning of coke as rapidly as they are filled. The regular production of coke started this week.

SLOCAN DISTRICT.

In order to provide funds for opening up a road to the property and driving a deeper tunnel, the Fisher Maiden-Troy M. Co., operating on Four Mile creek, near Slocan City, has decided to reorganize. They have a carload of ore sacked ready for shipment, awaiting completion of the road, in addition to 300 tons of second grade ore, averaging forty-two ounces per ton in silver.

KLONDIKE.

Dawson reports tell of another strike on the Pelly river, near its head; and a steamer has gone up the river with forty men to stake claims. The Yukon is said to be lowering so rapidly that before the end of August only the lightest draft vessels will be operating.

Reports from Dawson say another gold strike has been made on the upper Pelly river, 26 miles above Hoole canyon.

MEXICO.

CHIHUAHUA.

J. P. Jones, E. Davis and J. P. Cowen of New York are reported to have bought the Capusaya group of mines adjoining the mines of Pedro Alvarado, near Parral.

Operations will be resumed at the Prieto mine at Parrai, says Superintendent Terry, next week.

The roasting furnaces of the Red Hill mine in Cerro Colorado, in Parrai district, are ready for operation and, with the 100-ton lixiviation plant, will be started up this week, says W. E. Regers, manager.

The Cigarrero mine in Sierra Amaloya section is shipping eighty tons of ore per day. The location is on a mountain 5 miles south of the Mexican Central's branch from Jimenez to Parral. The ores are silver-lead, carrying gold values.

P. Ginther, manager of the Encinillas Mines, Ltd., reports the company's 80-ton smelting plant at Santa Rosalia will be finished this month.

On the Palmillo mine, near Parral, a power plant is being built by the owner, P. Alvarado, and another is under construction on the properties of the Consolidated M. Co. of Parral. Leases and bonds have been taken by J. C. Brooks on the San Diego mine at Santa Barbara; by the Saginaw M. & M. Co. on the Quatro de Julio of Parral; by the Stillwell people (the Kansas City, Mexico & Orient Railroad) on the Germania, which has 45 pertenencias adjoining the Refugio mine of Parral. Development work is being started on all of these mines.

DURANGO.

The Chicago men, F. J. Lichtenberger manager, who took over the four mines at Januco de Coronado, have organized the Coronado-Durango M. Co. The claims are the La Union, La Peruna, Gran Senora and Zaragoza.

It is proposed to build a railroad from Caliacan in Jalisco to Topia in Western Durango. The matter is being considered by men from Durango and the United States to handle the tonnage from the mines. Topia is a silver-lead camp, the principal mines of which are owned by the Selby & Miller M. Co. The property has 6000 feet of development and a 100-ton concentrating mill.

The American Security & Trust Co., of Detroit, Mich., are opening up a group of fifty-seven pertenencias adjoining the Mina Grande de La Paz, 1 mile from Yerba Buena. The Durango M. Co. is being organized to operate the group and machinery will be put in.

GUERRERO.

The Mitchell Copper Co. is preparing to build a railroad from its mines at La Diche to Acapulco on the coast, a distance of 60 miles.

JALISCO.

The Ampara M. Co. has paid the $230,000 balance on the Santo Domingo mine, near Etzatlan, and taken possession. There is claimed to be a large amount of low-grade ore in the mine, which will run one kilogram of silver and ten grams of gold to the ton.

OAXACA.

Gold placers have been located near Tuxtepec and a number of men have started development.

SONORA.

It is reported that Phelps, Dodge & Co., owners of the Copper Queen mine at Bisbee, Ariz, and the Nacozari copper mines at Nacozari, are making arrangements to employ Chinese labor at Nacozari instead of Mexicans. It is also understood it is intended to employ Chinese labor on the railroads. The mine company claims that Mexican labor is uncertain and scarce in Sonora, and that white labor cannot be obtained. It is estimated that 4000 Chinese have landed at Guaymas within the last sixty days and have been given employment.

E. S. W. Drought, manager of the Sonora Dev. Co. at Nacozari, reports the company's 10-stamp mill completed.

NEW ZEALAND.

The Con. Gold Fields of New Zealand, at Reefton, July 13, report: Progress Mines—Crushed 4852 tons of ore, yielding bullion (including tailings cyanided, £739, and sulphurets, £1008), valued at £9320; expenses, 14s 4½d per ton. Golden Fleece—Crushed 1230 tons of ore for bullion (including tailings cyanided, £276, and sulphurets, £95), valued at £2307; expenses, £1 6s 1½d per ton. Wealth of Nations—Crushed 1014 tons of ore for bullion (including tailings cyanided, £310, and sulphurets, £55), valued at £1420; expenses, 17s 6d.

The Komata Reefs G M. Co. report gold discovered in Roma Reef No. 4, level N.

The Waihi Grand Junction G. Co., Ltd., at Waihi, report: Diamond drill hole at angle of 69°. Core assays—At depth of 509 feet, $50; 531 feet, $40; 540 feet, $25. The foot wall of the lode is not yet reached. Lode No. 2, in northeasterly direction 130 feet, shows width of lode 4 feet; assay value, $25.

SIBERIA.

A Moscow firm—N. & P. A. Korzenetzof—has been granted permission by the Irkutsk department of mining to work asbestos mines near the Kutai, a tributary of the Angara river. The asbestos layers are found 7 feet from the surface. There are some asbestos mines in the Urals, in European Russia, but the larger part of the asbestos used for insulators in Russia is imported, writes R. T. Greener, United States commercial agent at Vladivostok.

TASMANIA.

The Briseis Tin Co. report for period ending June 30: Ore in stock, including black tin at mine and metallic tin at Launceston, 19 tons; overburden removed, 24,900 cubic yards; drift sluiced, 31,000 cubic yards; black tin cleaned up, 39 tons 14 cwt.; average total sluiceheads of water available from all sources, 185.

PERSONAL.

E. C. ENGELHARDT is now at Eltoro, Cal.

H. RAMSAY, a miner of Tonopah, Nev., is in San Francisco, Cal.

R. J. WALTERS has returned to Denver, Colo., from Vuican, Colo.

H. H. WILLISON has returned to Henson, Colo., from Denver, Colo.

D. G. JEWETT, formerly of Chloride, Ariz, is now in Los Angeles, Cal.

S. J. WILLIS has returned from Nevada to Waunita, Gunnison county, Colo.

J. H. NEALE, a mine owner and operator of Sonora, Cal., is in San Francisco, Cal.

GEO. JOHNSTON has returned to San Francisco, Cal., from a business trip to Mexico.

J. B. LUDDY is manager of the Sand Pile mine, near Forest Home, Amador county, Cal.

E. BAMBERGER of Salt Lake City, Utah, is on a mining business trip through Idaho and Oregon.

M. G. BANKS is superintendent of the New Era mine, near Searchlight, Lincoln county, Nev.

F. A. MCINTOSH has removed from Supai Agency, Ariz., to Woodstock, Ontario, Canada.

H. CARRY, C. E., formerly of Vancouver, B. C., has removed to Chalk River, Ontario, Canada.

J. A. MCINTYRE, of the South Keystone mine at Amador City, Cal., is in San Francisco, Cal.

E. C. VOORHIES, superintendent of the Lincoln mine, Sutter Creek, Cal., is in San Francisco, Cal.

C. L. HERRICK is superintendent and manager of the Socorro G. M. Co. at Magdalena, N. M.

W. G. SCOTT, superintendent of the Black Oak mine, near Soulshyville, Cal., is in San Francisco, Cal.

J. A. JACKSON, interested in oil properties near Fullerton, Orange county, Cal, is in San Francisco, Cal.

R. A. SKINNER has resigned as superintendent of the Globe mine, near Dedrick, Trinity county, Cal.

PRESIDENT SMITH of the Old Dominion C. M. Co., is at their mines at Globe, Ariz., from Boston, Mass.

L. C. DU BOIS, formerly of Lake City, Colo., has opened an assay and ore shippers' office at Salida, Colo.

J. C. GILL of Massachusetts, president of the Shannon Copper Co., at Clifton, Ariz, is visiting the mines.

J. A. FRASER is superintendent of the Ragnarok group of mines, in Oro Blanco district, near Arivaca, Ariz.

MANAGER R. B. HUGHES returned to Deadwood, S. D., last week from Chicago, Ill., on business for the Holy Terror M. Co.

L. COLBATH is assayer and chemist for the Gold Vein M. Co, at the Wedge mine, near Marysvale, Utah.

S. C. BIRD of Bridgeport, Conn., is superintending operations at the Angel mine, west of Wickenburg, Ariz.

A. J. MCQUAID has returned to Pueblo, Colo., from an examination of mines near Searchlight, Lincoln county, Nev.

J. BARRY of Los Angeles, Cal., owner of the Sunrise mine, near Chloride, Mohave county, Ariz., is at Chloride.

G. H. I. HIBERLEIN is superintendent of the smelter on the Indian Queen mine on Birch creek, near Dilion, Mont.

B. C. RIBLET, formerly of Nelson, B. C., now makes his headquarters at 601 Empire State Bldg., Spokane, Wash.

W. H. ANDERSON of Aspen, Colo., is superintendent of the Bassick G M. Co, near Silver Cliff, Custer county, Colo.

JAS. L. BRYSON, superintendent of the Mazeppa mine, near Stent, Tuolumne county, Cal., is in San Francisco, Cal.

G. JUNG has returned to Cincinnati, O, from Gunnison county, Colo., where he has been looking after mining interests.

G. LAVAGNINO, formerly manager of the Old Telegraph mine, is manager of the Butterfield mines at Bingham, Utah.

E. H. BARTON, superintendent of the Yellow Aster mine at Randsburg, Cal., is in San Francisco, Cal., on mining business.

A. J. OSGOOD is superintendent of the Western Union Oil Co., operating near Santa Maria, Santa Barbara county, Cal.

RICHARD P. WILLIAMS, of Greenwood, B. C., succeeds F. R. Mendenhall in the British Columbia representation of the Rand Drill Co.

G. H. CLEVENGER has succeeded J. B. Empson, resigned, in charge of the cyanide works of the Dakota G. M. Co., at Deadwood, S. D.

A. H. BUCK, who has been in Maguarichic, Chihuahua, Mex., surveying the properties of the La Luz G. M. Co., is in Colorado on a visit.

F. B. SCHERMERHORN, general manager of the Three Bears M. Co. of Jarilla, N. M., has returned there from a trip to Parral, Chihuahua, Mex.

F. M. SYMES, superintendent of the Gold Coin mine, Victor, Colo., has returned there from a trip through the western part of the State.

T. L. HENDERSON, of St. Louis, Mo., is president of the Great Western G. M. Co., operating the Afterthought copper mine in Shasta county, Cal.

A. F. NATHAN, manager of the Stillwell M. Co., returned to Chihuahua, Mex., last week from a month's trip to Kansas City, Mo., and the East.

F. DALTON, of Salt Lake City, Utah, is superintendent of the Gold Vein M. Co., operating the Wedge mine, near Marysvale, Piute county, Utah.

A. R. BOYNTON, of Chicago, Ill., vice-president of the McKinnon G. M. Co., operating at Silver City, Idaho, is at the mines, from Salt Lake City, Utah.

JOHN ROSS, JR, superintendent and manager of the Wildman & Mahoney M. Co. at Sutter Creek, Cal., has gone to New York and Boston on mining business.

W. FORRESTER is mill superintendent at the Latham mines, in Spruce Mountain district, south of Wells, Nev., and E. H. Osborne is superintendent of the mine.

J. S. WYATT, formerly manager of the Mountain Lion mine at Republic, Wash., has gone to Bourne, Baker county, Or, to take charge of the Eureka & Excelsior mine.

G. W. MEYERS, representing the Chrome Steel Works of Brooklyn, N. Y., on the Pacific coast, left San Francisco, Cal, on the 4th inst. for New York, to be absent six weeks.

S. GUGGENHEIM of the American S. & R. Co., accompanied by E. L. Newhouse, is inspecting the plants controlled by the company in Utah and Montana after a visit to Colorado.

H. RAMDOHR, late millman at the Chloride-Bailey mine, near Dedrick, Trinity county, Cal, is superintendent of the Globe mine in the same district, vice R. A. Skinner, resigned.

J. W. SISSON of New York, N. Y., president, and C. H Barney of Boston, Mass., vice-president, of the Troy-Manhattan C. Co., are visiting the company's mines at Troy, Pinal county, Ariz.

C. K. MCCORNICK of Salt Lake City, Utah, is at the Gold Roads mines and mill

at Acme, Mohave county, Ariz , and will leave for Paris next week to attend the annual meeting of shareholders.

J O. HARRON, THOS. RICKARD AND J. M. MCCONE, of the firm of Harron, Rickard & McCone, mining machinery manufacturers of San Francisco, Cal., go to-day to the "high jinks" of the Bohemian Club, in Marin county, Cal.

JUAN FELIX BRANDES has gone to New Mexico to examine the Fraser Mountain Copper Co 's property. The Transcontinental M. Co. of Denver, Colo., have recently appointed him their consulting engineer.

C. F. HOFFMAN AND J. D. HOFFMAN, mining engineers, returned to San Francisco, Cal , last week from a four months' trip through the principal mining districts of Alaska, in the interest of the Guggenheim Exploration Co.

J. H. MEANS, formerly on the staff of the California State Mineralogist, is in London, England, where he recently returned from West Africa. Mr. Means expects to leave London for a trip to French Guiana, South America, on mining business.

FREDERICK WULFF, a civil and mining engineer of Mexico, has returned to Torreon, Chihuahua, Mexico, from a visit to Oakland, Cal , accompanied by his son, F. Wulff Jr , a mining student at the University of California, and they will engage in mining together.

L. R MEAD, long-time secretary of the Risdon Iron Works, San Francisco, and of later years well and widely known as proprietor of the famous Byron Springs, has re-entered San Francisco business life and resumed connection with the Risdon Iron Works as auditor.

SUPERINTENDENT E. R ABADIE of the Champion mine at Nevada City, Cal , of the Champion Mines Co., has been appointed general superintendent of their properties, with offices in San Francisco, Cal. This also places him in charge of the Southern Cross mines at Forhestown, Butte county.

Commercial Paragraphs.

THE Jeanesville Iron Works Co., through the Denver branch, has delivered to the Ajax G. M. Co., Victor, Colorado, a compound condensing pump, to be installed on the 1100-foot level.

"GRAPHITE" for August is received. It is a model of what a "house organ" should be. It is issued monthly "in the interest of Dixon's graphite productions," hy the Jos. Dixon Crucible Co., Jersey City, N. J.; is full of good things, and any one reading it must come to the conclusion that a concern able to get up such a smart little publication must surely furnish a good product in their regular business.

JOHN A. YEATMAN & Co., hydraulic engineers, San Francisco, Cal., report the ten Adams hydraulic lifts sent to Nome district, Alaska, this season, in operation and giving satisfactory results. In one instance the machine is elevating to 21 feet, with pressure of 39 pounds per square inch (equivalent to 90 feet head)—exceeding the guarantee of 5 feet pressure head for each foot elevated. Two of the lifts are operated under artificial head produced by two-step centrifugal pumps.

ON August 1 the firm of John Johnson & Co., filter press manufacturers of Franklin Square, New York, was incorporated at Albany, with a capital stock of $110,000, fully paid in. This business was established in 1878, and was at the start an off shoot of S. H. Johnson & Co., Ltd., of London, England. The officers of the incorporated company are M. Hopkins, president; J. Johnson, vice-president and treasurer, R. Anderson, secretary. The board of directors include, besides the officers mentioned, S. H. Johnson, of London, and H. J. Linder and E J. West, of New York. The plant is equipped with special machinery for filter press manufacture, designed hy Mr. Johnson.

THE C. O. Bartlett & Snow Co. of Cleveland, Ohio, announce that, at considerable expense, they erected at their works two of their dryers—one of their Triumph steam dryers and one of their direct-heat rotary dryers—and that they will be glad to make careful test runs, dry any kind of material, either by steam or direct heat, for intended purchasers under the following conditions: All material to he shipped, charges prepaid. When possible, send some competent man to take charge of the results, such as cost, time required, amount of moisture taken out, etc. They make no charges for use of dryer or power; they will charge only actual cost for labor required for handling the material to be dried. They say: "Send 500 pounds or a carload and we will show you actual results. This, we trust, offers an opportunity which will be appreciated hy many."

Catalogues Received.

The Denver Engineering Works Co., of Denver, Colo., have issued Bulletin 18, entitled "Gears." This publication is profusely illustrated and contains much valuable information on the subject of gears and gear cutting machinery; the horsepower of gearing, maximum speed, etc.

W. Ainsworth & Sons of Denver, Colo., have issued a handsome new Catalogue A-3, the advance sheets of which have been received. It is finely illustrated and fully descriptive of the excellent assayers' halances and supplies made by them. The catalogue will he sent on application.

Catalogue No. 39 from the F. M. Davis Iron Works Co., Denver, Colo , is descriptive of their new establishment at 1737 Champa street, a metallurgical department, in charge of Mr. W. B. Milliken, which is equipped and in operation for the purpose of assaying and testing ores in any quantity up to and including carload lots. The catalogue gives a complete list of prices for assays, chemical determinations, etc.

"Some Details as to Smelting Practice and Equipments" is the modest title of a treatise just published hy the Colorado Iron Works Co., of Denver, Colo , and which is replete with just the kind of information any one interested therein would like to have. The Colorado Iron Works Co. says "this pamphlet is not written as a price list, but to cover certain information as to smelting practice and set forth our manufactures in that line." The value of such a pamphlet is manifest; it does not contain theories or notions, heing compiled from actual smelting practice, and written hy specialists in their line. It is well illustrated and is a notable addition to technical literature on the subjects of which it treats.

Books Received.

"The Art of Pattern Making," by J. McKim Chase, is the title of a volume 12mo. vi + 254 pages, with 215 figures. It is a hook of value to the pattern maker, iron moulder and founder. Every phase of pattern making for castings is described and carefully illustrated. It embraces the practical experience of many skilled pattern makers. Price, $2.50; John Wiley & Sons, New York; Chapman & Hall, Ltd., London.

"Earth Work and Its Cost" is the title of a neat volume of 244 pages, hy Halbert P. Gillette. It deals with the art of estimating the cost of handling earth by means of various devices; transporting the loosened earth by means of wheelharrows, carts, dump carts, scrapers, wagons, steam shovels, etc It also goes into excavating by dredging, hydraulickling and by other means. The book is illustrated and will prove of use to those engaged in the work of excavating on a small or large scale. $2; The Engineering News Publishing Co , New York City.

New Patents.

DEWEY, STRONG & CO.'S SCIENTIFIC PRESS PATENT AGENCY, 330 Market St., S. F., has official reports of the following U. S. patents issued to Pacific coast inventors:

FOR THE WEEK ENDING JULY 28, 1903.

734,408.—BOUGIE—F. R. Bachler, Oxnard, Cal.
734,802.—MUSICAL INSTRUMENT—G. H. Blair, Spokane, Wash.
734,805.—HORSE GROOMING MACHINE—A. & P. Eglund, San Jose, Cal
734,664.—ROPE SOCKET SWIVEL—H. M. Brittan, S. F.
734,809.—BOTTLING MACHINE—W. E. Brown, Los Angeles, Cal.
735,030.—SUCKER ROD JOINT—E. B. Campbell, Bakersfield, Cal.
734,821.—PUZZLE—E. S. Cobh, Los Angeles, Cal.
734,832.—PAWL AND RATCHET—H. W. Cooley, Lonerock, Or.
734,685.—STAMP MILL—W. A. Dalton, Tucson, Ariz.
735,014.—OIL BURNER—A. Davis, S. F.
734,833.—UNDER REAMER—E. Domble, Santa Paula, Cal.
734 533.—STEAM ENGINE—C. L. Fouts, Eureka, Cal.
734,848.—CARBURETOR—W. A. Gill, Portland, Or.
734,552.—ICE VEHICLE—I. N. Henness, Ilwaco, Wash.
734,877.—GAME—F. E. Hunt, Buckley, Wash.
734,712.—OIL BURNER—F. W. H. Jahn, Los Angeles, Cal
734,881.—BOTTLE—F. Jost, Susanville, Or.
734,580.—WIRE CLAMP—D. Lockhart, Hoquiam, Wash
734,920.—TROLLEY CATCH—G. W. Maxwell, Los Angeles, Cal.
734,742.—STEERING DEVICE—M. W. Patrick, Niles, Cal.
734,747.—NEEDLE—F. J. Rabbeth, Redlands, Cal.
734,769.—PEN WIPER—J. J. Stanley, Vallejo, Cal.

Latest Market Reports.

SAN FRANCISCO, August 7, 1903.

METALS.

SILVER.—Per oz., Troy: London, 25½d (standard ounce, 925 fine); New York, bar silver, 55½c, refined (1000 fine): San Francisco, 55½c; Mexican dollars, 42¾c San Francisco, 42¾c New York.

COPPER.—New York: Standard, $13.25; Lake, 1 to 3 casks, $13.00@13.25; Electrolytic, 1 to 3 casks, $13.62½@13.75; Casting, 1 to 3 casks, $12.75; San Francisco: $13.00. Mill copper plates, $17.00; hars, 18@24c. London: £57 10s spot per ton.

There is no change in the copper market since last week. In the New York market the larger consumers feel safe in holding off and several of them report a considerahle shrinkage in the demand. The leading wire concerns report a very dull market with orders fully two-thirds less than a year ago. Wall Street is responsible for much of this dullness. New concerns cannot he started and new construction has to stop. One new concern had put in specifications calling for several miles of wire, hut the slump in Wall Street has scared investors and the company will not he floated till the spring.

LEAD.—New York, $4.20; Salt Lake City, $3.50; St. Louis, $4.00; San Francisco $4.50, carload lots; 4¼c 1000 to 4000 lbs.; pipe 5½, sheet 6, bar 5½c; pig, $4.75. London: £10 18s 9d per long ton=2.75c per lb.

SPELTER.—New York, $5 87½; St. Louis, $4.85; London, £20 2s 6d per ton; San Francisco, ton lots, 6½c; 100-lh lots, 7c.

ANTIMONY.—New York, Cookson's, 9¾c; Hallett's, 8½c; San Francisco, 1000-lb. lots, 7½c; 300 to 500 lbs., 7½c; 100-lb. lots, 10c.

TIN.—New York, pig, $27.25@27 50; San Francisco, ton lots, 28½c; 500 lbs., 29c; 200 lbs., 29½c; less, 30c; bar tin, ℔ lb, 30c @32½c. London, £125 5s spot.

PLATINUM.—San Francisco, crude, $18.00 ℔ oz.; New York, ingot, $19.00 per Troy oz Platinum ware, 75@80c per gram.

QUICKSILVER.—New York, $44.50@46.00; large lots; London, £8 15s; San Francisco, local, $44.50 ℔ flask of 76½ lbs.; Denver, $49.50. Export, $43.50.

BABBITT METAL.—San Francisco, No. 1, 10c; No. 2, 7c; No. 3, 6½c; extra, 17½c; genuine, 35c; Eclipse, 37½c.

ALUMINUM.—New York, No. 1, 99% pure ingots, 35c; No. 2, 90%, 30c to 34c.

SOLDER.—Half-and-half, 100-lb. lots, 18.75c; San Francisco, Plumbers', 100-lb. lots, 15 50c.

NICKEL.—New York, 50@60c ℔ lb.; ton lots, 45@48c.

STRUCTURAL MATERIALS.

IRON.—Pittsburg, Bessemer plg, $19.50 @19.85; gray forge, $17.10; San Francisco, bar, 3c ℔ lb., 3½c in small quantities.

STEEL.—Bessemer billets, Pittshurg, $27.00@29.00; open hearth billets, $28.00; San Francisco, bar, 7c to 12c per lb.

No. 1 railroad wrought	14.50@15.00
No. 1 cast, net ton	14.50@15.50
Iron rails	20.00@21.00
Car wheels	20.00@21.00
Cast borings	5 50@ 6 50
Turnings	11.00@12.00

LUMBER.—(Retail): Pine, ordinary sizes, $20.00@22.00; extra sizes higher; redwood, $22.00@23.00; lath, 4 feet, $4.25 @4.50; pickets, $19.50; shingles, $2.35 for No. 1 and $2.00 for No. 2; shakes, $13.50 for split and $14.50 for sawed; rustic, $26.00 @32.00.

NAILS.—Per keg (list prices): No. 20d to 60d, Wire, $3.25; Cut, $3.35; 10d to 16d, Wire, $3.35; Cut, $3.35; 8d, Wire, $3.40; Cut, $3.40; 6d and 7d, Wire, $3.50; Cut, $3.50; 4d and 5d, Wire, $3.60; Cut, $3.60; 3d, Wire, $3.75; Cut, $3.75; 2d, Wire, $4.00; Cut, $4.00. Special rates for carload lots.

LIME.—Santa Cruz, $2.25; Roche Harhor, $2.25 per bhl.

CEMENT.—Germania, $2.50 @ 2.75; Hewmoor, $2.90; Trowell, $2.90; Portland, $2.50@2.75 per bhl.

GENERAL SUPPLIES.

POWDER.—F. o. b. San Francisco: No 1. 70% nitro-glycerine, per lb., in carload lots, 15½c; less than one ton, 17½c. No. 1*, 60%, carload lots, 13½c; less than one ton, 15½c. No. 1** 50%, carload lots, 11½c; less than one ton, 13½c. No. 2, 40%, carload lots, 10c; less than one ton, 12c. No. 2, 35%, carload lots, 9½c; less than one ton, 11½c. No. 2** 30% carload lots, 9c; less than one ton, 11c. Black blasting powder in carload lots, minimum car 728 kegs, $1.50 per keg; less car lots, $2 per keg.

CAPS.—3x, $5.50 per 1000; 4x, $6.50; 5x, $8; Lion, $9, in lots not less than 1000.

FUSE.—Triple tape, $3.50 per 1000 feet; double tape, $3.00; single tape, $2.65; Hsmp, $2.10; Cement No. 2, $3.00; Cement No. 1, $2.65, in lots of 3000 feet and up.

CANDLES.—Granite 6s, 16 oz., 40s., 10½c ℔ set; 14 oz., 40s., 9½c.

CHEMICALS.—Cyanide of potassium, 98%-99%, jobbing, 24@25c ℔ lb.: carloads, 23@24½c; in tins, 35c; soda ash, $2.00 ℔ 100 lbs.; hyposulphite of soda. 2½@2½c ℔ lb.; caustic soda, in drums, 3@3½c ℔ lb; Cal. s. soda, hhls., $1.25@1.50 ℔ 100 lbs.; sks., $1.05; chlorate of potash, 12@13c; nitrate of potash, bbls., 10c; caustic potash. 10c in 40-lb tins; borax concentrated, 7@8c ℔ lb.; roll sulphur, 4@6c; powdered sulphur, 2@ 3c; flour sulphur, French, 2@3c; alum, $2.00@2.25; California refined, 2@2½c; sulphide of iron, 9c ℔ lb; copper sulphate, 5@7c; chloride of lime, spot, $2.50@2.75; sulphuric acid, in carboys, 66% B, 2½o ℔ lb.; nitric acid, in carhoys, 8c ℔ lh.

OILS.—Linseed, boiled, bbl., 44c; cs., 49c; raw, bbl., 42c; cs., 47c; Lucol oil, boiled, bbl., 41c; cs, 49c; raw, bbl., 39c; cs, 49c. Kerosene—Pearl, per gal., 20½c; Astral, 20½c; Star, 20½c; Extra Star, 24½c; Eocene, 23½c; Elaine, 26½c; Water White, in bulk, 14½c; Mineral Seal, iron bbls., 18½c; wooden hhls., 21c; cs, 24c; Mineral Sperm, cs, 26½c; Deodorized Stove Gasoline, bulk, 17c; do., cs., 23½c; 86° Gasoline, bulk, 21c; do., cs., 27½c; 63° Naphtha or Benzine, deodorized, in bulk, per gal., 16c; do., in cs., 22½ c; Lard Oil, E. W. S., bbl., $1.00; cs., $1.05; Neats-foot Oil, pure, bbl., 75c; cs., 80c; Sperm, crude, 70@60c; Natural White, 65c; Bleached do, 50c; Whale Oil, cs, 50@55c.

COAL.—San Francisco, coast, yard prices: Wellington, $8.00; Seattle, $6.50; Coos Bay, $5.50; Southfield, $8.00. Cargo lots, Eastern and foreign: Wallsend, $6 .50 Brymbo, $7.50; Pennsylvania, hd., $14. 00 Scotch, $8; Cumberland, $12; Cannel, $9.00; Welsh Anthracite, $11.50; Rock Springs, $9.50, long ton; Colorado Anthracite, $14.00. Coke, $10.50 per ton in bulk, $13 in sacks; Sunnyside, $8 50, long ton.

WHITE LEAD.—Per lb., in kegs: 500 lbs. and over at one purchase, per lb., 6c; less than 500 lbs., per lb., 6½c; in 25-lb. tin pails, ½c per lb. above keg price; in 1 and 5 lb. tin cans, 100 lbs. per case, ½c per lb. above keg price. Dry Lead—In bhls., 1 ton and over, 6c; do. in kegs, 6½c.

RED LEAD.—500 lbs. and over at one purchase, per lb., 6c; less than 500 lbs., 6½c.

LITHARGE.—Pure, in 25-lb. bags, 8 @9c per lb.

BONE ASH.—Extra No. 1, 5@6c per lb. No. 1, 4@5c.

BORAX.—Concentrated, 7@9c per lb powdered, 9@12c; fused, 25@30c.

BORAX.—Crystal, 7c; calcined, 25c.

MANGANESE.—Pure, ℔ lb., 60c.

SODIUM.—Metal, ℔ lb., $1.00.

MOLYBDENUM.—$2 per lb.

CHROMIUM.—(90% and over) per lb., $1.00.

BISMUTH.—Subnitrate, per lb., $1.60.

MERCURY.—Bichloride, ℔ lb., 90c.

PHOSPHORUS.—(American) ℔ lb., 75c.

SILVER.—Chloride, ℔ oz., 90c@$1.00; nitrate, 55c.

ALUMINUM.—No. 1, 99%, small lots, 37c ℔ lb.; 100 lbs., 35c; 1000 lbs., 34c; ton lots and over, 33c, Pittsburg. No. 2, 90%, small lots, 34c; ton lots and over, 31c, Pittsburg.

URANIUM.—Oxide, ℔ lb., $3.50.

ZINC.—Metallic, chemically pure, ℔ lb., 50c; dust, ℔ lb., 10c; sulphate, ℔ lb., .04c.

(These prices are wholesale, f. o. b. San Francisco, unless otherwise noted.)

SITUATIONS WANTED.

EXPERT DIAMOND DRILL FOREMAN AND Setter of twenty years' experience in various parts of the world. At present employed, but desires change and a permanent position in the West. Can bring one or two operators as desired. Address "Diamond," this office.

EXPERIENCED ASSAYER, MILLMAN AND Analyst is open for engagement—amalgamating, concentrating, cyaniding, stamps, rolls, Chilian mills, Wilfley tables, vanners, etc. Speaks Spanish. Address P. O. Box 449, Los Angeles, Cal.

MINE SUPERINTENDENT WANTS POSITION with a substantial company that has a mill on property. A qualified mining engineer who can run a mine or mill, cyanide plant, assaying and surveying. Address "Mining," this office.

MINE SUPERINTENDENT DESIRES POSITION with reliable company to develop gold or copper property. Competent in mining, milling, smelting, assaying, draughting, etc. Good all round man. Speaks Spanish. Address "Superintendent," care of this office.

MINING ENGINEER AND METALLURGIST, at present general manager of a large mining concern in Mexico, desires to change his position. Would need four months' notice. Address F.B.A.S., care of this office.

WANTED. — POSITION BY EXPERIENCED Millman; 18 years' experience in operating jigs, Frue vanners and Wilfley tables. Best references furnished. Address F. L., care of this office.

TO COPPER MEN.

An experienced copper metallurgist would arrange to change from present engagement upon suitable representations.

Is thoroughly familiar with all details of operation of large smelting plants, the handling of labor, etc., and would consider a propoeition to engage as euperintendent or metallurgist of plant already in operation, or to design and erect contemplated works, or act as consulting engineer.

In replying please give as fully as consistent details of location, salary, proposed terms of contract, etc, which will he treated as strictly confidential.

Address "Amargosa," care of Mining and Scientific Press.

WANTED.

CAPABLE ENGINEER OF GOOD STANDING and experience would like to purchase an interest in an estahlisbed engineering business—mining or civil. Only a business capahle of expansion and doing high grade work is desired. Address "Experience," care of Mining and Scientific Prese.

WANTED--MILL TAILINGS,

Gold, silver or lead, in New Mexico, Arizona or old Mexico. Will huy or lease. Give location, quantity and value. A. E. VAN VELSAN, Telluride, Colorado. Box 181.

Backing Desired to Look Up Mining Properties.

References exchanged. Addrese "R", this office.

WANTED—Nitrate of Soda Deposits on the Pacific Coast.

Address "Nitrate," Mining and Scientific Press.

Valuable Books for Prospectors and Miners

Orton.—Underground Treasures: How and Where to Find Them. A Key for the Ready Determination of all the Useful Minerals within the United States. By James Orton, A. M., late Professor of Natural History in Vassar College, N. Y., etc. A New Edition with an Appendix on Ore Deposits and Testing Minerals with the Blow-Pipe. Illustrated. Price.....$1.50

Osborn.—The Prospector's Field Book and Guide in the Search for and Easy Determination of Ores and other Useful Minerals. By Prof. H. S. Osborn, LL.D. Author of "A Practical Manual of Minerals, Mines and Mining." Illustrated by 58 engravings. Fifth edition, revised and enlarged. 315 pages, 12mo. Price.....$1.50

Osborn.—A Practical Manual of Minerals, Mines and Mining: Comprising Suggestions as to Localities and the Associations of all the Useful Minerals. Full descriptions of the Most Effective Methods of Both the Qualitative and Quantitative Analyses of Each of these Minerals and Hints upon the Various Operations of Mining, including Architecture and Construction. By Prof. H. S. Osborn, LL.D. Illustrated by 171 engravings. Second edition, revised and enlarged. 393 pages, 8vo. Price.....$4.50

Lieber.—The Assayer's Guide: or, Practical Directions to Assayers, Miners and Smelters, for Tests and Assays, by Heat and by Wet Processes of the Ores of all the Principal Metals, of Gold and Silver Coins and Alloys, and of Coal, etc. By Oscar M. Lieber. A new, revised and enlarged edition. Illustrated. 283 pages, 12mo. Price.....$1.50

Erni and Brown.—Mineralogy Simplified: Easy Methods of Identifying Minerals including Ores, by Means of the Blow-Pipe, by Flame Reactions, by Humid Chemical Analysis, etc. A New and Revised Edition. 411 pages, illustrated by 96 engravings. Pocket-book form, morocco gilt edges. Price.....$2.50

Duncan.—The Practical Surveyor's Guide: Containing the necessary information to make any person of common capacity a finished land surveyor, without the aid of a teacher. By Andrew Duncan, Land Surveyor and Civil Engineer. A new, revised and greatly enlarged edition. Illustrated by 72 engravings. 214 pages, 12mo. Price.....$1.50

☞ *By mail free of postage at the publication prices to any address in the world.*

☞ *Illustrated Circulars giving full tables of contents of the above books sent free of postage to any one in any part of the world sending his address.*

THE BEST LUBRICATOR IS THE CHEAPEST IN THE END.

The Steam Cheet and Cylinder are the vital parts of a steam engine and their surfaces must be kept perfectly lubricated in order to get the best returns from the steam used. If the surfaces are not properly lubricated, the resulting friction will waste a percentage of power which would otherwise be converted into useful work.

In addition to this, there is the liability that the Valves and Cylinders may become cut or injured. The loss in fuel alone, due to imperfect lubrication, would very soon amount to more than the price of a first-class Lubricator, and the cost of repairing the cut Valves is also a serious item. These losses can be avoided by equipping your engine with a DETROIT LUBRICATOR. They are the result of more than twenty-five years' experience with all kinds of engines. More than 700,000 of these DETROIT LUBRICATORS have been sold in all parts of the world and fully nine-tenths of the prominent American builders of steam engines use them exclusively.

Catalogues showing our full line of Sight Feed Lubricators, Oil Pumps, Glass Oilers, Oiling Devices, etc., will be sent on application.

DETROIT LUBRICATOR CO., DETROIT, MICH.

Mining in Alaska.

When one hears Alaska spoken of as a mining region, the natural impression is that of an ice-bound region under perpetual snow, where the miner suffers many hardships, but eventually finds deposits of gold which quickly reward him for all his perils and hardships; but there is little more of romance in mining in Alaska than is found in other regions, and the percentage of successful adventurers is not greater than in new countries and districts elsewhere. There is one advantage, however, and that is of somewhat doubtful character; the country has not as yet been thoroughly prospected, and as the territory is of vast extent, it is not unlikely that new discoveries will still continue to be announced for many years. Since 1898 the United States Geological Survey has been systematically investigating the mineral resources and geology of Alaska, and much valuable information has been given to the world on conditions in Alaska as they really exist. Thus far, mining is largely in gravels of the streams and sands of the seashore, quartz mining having made but small progress. This is due partly to the natural disadvantages of the country, and to the expense of transportation, but more largely to the fact that few quartz veins, outside of Douglas Island and some other of the islands of the coast, have as yet been discovered which warrant the expense of equipment. No one believes that the discovery of a rich vein of gold ore in Alaska would not be followed by the prompt equipment of the mine with the latest and best machinery. Many phenomenal finds have been reported from time to time in the various districts, but as yet none of these "finds" have developed into a mine attracting attention by its richness. However, the gold in the placers came originally from rock in place, and valuable discoveries of quartz veins may yet be made.

The glaciers of Alaska are a prominent factor in carving the topography of the country, and the vast fields of gravel found there are largely of glacial origin. Then, too, moss covers almost the entire region, and these two things render prospecting for veins difficult. In some of the best placer districts the evidence thus far obtained indicates that the gold of the placers was derived from the erosion of a formation in which were innumerable rivulets and seams containing gold, there being no veins of workable size. This condition is not anomalous. In California the rich gravel deposits of the Forest Hill divide appear to have derived their gold from a similar source, as there is not sufficient vein-quartz bearing gold tributary to the placers of the ancient rivers to have produced the large amount of gold found in the gravels although quartz veins of large size are not lacking.

The American Mining Congress.

The American Mining Congress meets at Deadwood, South Dakota, Sept. 7 to 12. In this movement the Black Hills Mining Men's Association is taking an active part, and a great deal is expected from this meeting of the Congress, the primary object of which was to influence, as far as possible, the creation of a national Department of Mines and the appointment of a cabinet officer to represent the department. The MINING AND SCIENTIFIC PRESS has repeatedly pointed out the desirability of having a Department of Mines created, but thus far no positive steps have been taken by Congress in this direction. It is to be hoped that the American Mining Congress may eventually wield sufficient influence at Washington to bring about the desired end. In the meantime, however, the Mining Congress will take up and discuss various mining and metallurgical topics, and the meeting will afford an excellent opportunity for leading mining men from widely separated regions to form personal acquaintances, with an interchange of ideas which will prove, individually and collectively, valuable to those attending the Congress, and to the mining world at large.

Retaliatory Measures.

The miners who were recently driven out of Idaho Springs, Colo., by a deputation of citizens, have appealed to the District Court of the county at Georgetown, and Judge Owens issued warrants for the arrest of forty-seven of them. After a hearing they were put under bonds to keep the peace. Altogether eighty warrants were issued. Among those placed under arrest were the acting Mayor and members of the City Council of Idaho Springs and other municipal officers, leading merchants, citizens, bankers and mine operators. Learning of the issue of the injunction of the court fourteen of the eighteen miners driven out returned at once to Idaho Springs, where four of them were promptly arrested and placed in jail charged with complicity in blowing up the Sun and Moon transformer house, and warrants are out for several others. The exiled miners have taken another step in the matter by filing suits against twelve members of the Citizens' League, each asking for $10,000 damage. The next move in this game is looked forward to with interest by both sides.

Opportunities of the St. Louis Exposition.

Seldom, if ever, has the mining industry of the United States had a better opportunity to display the advancement made in mining practice and metallurgical science than that which will be afforded by the St. Louis Exposition in 1904. Several mining States have already announced their intention of making an elaborate display of their mineral wealth on this occasion, but there appears to be, with a few possible exceptions, no definite plan of what, or how, to exhibit, beyond the usual display of "specimen rock" in glass cases, which has been a customary feature of every exposition for years past.

The mining industry is the foundation of the great development and unparalleled prosperity of the United States. This great industry is entitled to something more in the way of an exhibition than a mere display of specimens in a case.

Specimens of the rich ores of gold, silver, copper, lead and zinc, etc., are attractive, and it has been found that "rich specimens" appeal more directly to the pocketbooks of investors than any amount of learned dissertation on ores, mines or mining. What the investing public seeks is satisfactory financial returns on investments, whether in mining or other industrial pursuits, and rich specimens promise these results to the mind of the average mining investor more surely than any amount of talk or literature. But there is another phase of the exhibition of the mineral resources of a State, and this is the exhibition, not only of the ores, but of the machinery employed in its treatment—not merely an exhibition as machinery, but actually in operation, crushing, concentrating, roasting and otherwise treating ores.

At several expositions of recent years mines have been exhibited in miniature, and these have proven a great attraction and given the general public a more comprehensive idea of "what a mine is like," perhaps, than anything else. One of these was a complete mine in miniature in the Colorado exhibit at the Midwinter Fair, held in San Francisco, Cal., in 1894. Many thousands of people visited this miniature mine, and mining men, as well as those unfamiliar with mines, pronounced it nearly perfect. The shafts with the swiftly moving cages; the long levels with trammers and cars; the stopes, winzes, and sumps, all were shown in detail, and the whole formed a most interesting object lesson, and one which made a lasting impression on the minds of all who saw it. Since a mine in miniature proved so popular, one naturally inquires why this exhibit attracted so much attention. It was due entirely to the mechanics of the ingenious model. The machinery was in motion. The cars moved to and fro on the tracks along the levels, the cages were operated in the shafts, and the whole thing presented an animated underground scene. If a mine in miniature, with its toy machinery, proves an object of such interest, how much more interesting and profitable would a full-sized plant be. At a mining fair held in San Francisco, Cal., in 1898 a hydraulic mine, and an underground drift mine in full size and operation, attracted much deserved attention and favorable comment.

Several States are already considering this idea, and it is stated that the Joplin, Mo., district will have a concentrating mill operating on zinc ores shipped in from that district, while a second mill will treat ores from the lead region of Missouri. The Black Hills of South Dakota will have a gold mill operating on the free-milling and concentrating ores from that section. In comparison with modern metallurgical methods, the Mexican exhibit will contain an arrastra, slowly grinding out the golden grains, representing side by side "the old times and the new" in mining. Lead and zinc furnaces will be in operation, actually turning out these metals from the ores from Missouri concentrated in the mills. It is also said that in the Mexican section the primitive method of smelting copper, as practiced for three centuries in that country, will form a feature of the exhibit.

In addition to the above, drilling machinery will be at work, actually boring deep holes, and it has been suggested that a coal mine may be opened under the exposition grounds, if it be as reported that coal seams underlie the site of the exposition.

All of this shows that unusual interest is centering about the mining exhibit, and the mining State that fails to take advantage of this opportunity to contribute some practical display to the general exhibit will not be in the race at all. A fine exhibition of ores and minerals is perfectly proper; but these are inert, and the public has seen them time and again at former exhibitions. It is now ready for something more than a specimen exhibit, and this is the opportunity for the several mining States to take advantage of the unusual and widespread interest displayed by the general public in mining. Rock breakers, stamps, crushing rolls and grinding devices all have a place in a competitive exhibit of this kind, as well as concentrators of the numerous types, jigs, buddles and hydraulic classifiers, and furnaces of various kind can also exhibit at this time to better advantage than ever before.

This is an opportunity, and every mining State should send the best it has to St. Louis, that the world may see what the United States is doing for the advancement of mining and metallurgy in this age of improvement and innovation in all branches of industry.

Advantages of Leasing System.

That the leasing system in mining camps, both old and new, is productive of good results, is evidenced by many districts where this system of working mines is in vogue. Leadville, Cripple Creek, and many other mining districts of Colorado, and also in Nevada, Idaho and elsewhere, are good examples of the results of the leasing system. By its means large territory can be thoroughly and promptly proven. In many places individuals or companies own large tracts of mineral land which they are unable to operate except at one or two points, owing to the great extent of their holdings. By dividing this land into blocks, and leasing the several blocks, the entire tract quickly becomes active, and the various veins and deposits are vigorously prospected and worked by men who usually thoroughly understand the business of mining, and who operate at a minimum of cost. The result is often satisfactory to all concerned and often to the commonwealth. The leasing system is particularly applicable to regions or districts producing high-grade ores. Low-grade camps must be developed by large capital, for there is not the incentive to the small investor and leaser found in those districts producing low-grade ores. There are many other districts where the leasing system would be beneficial and would quickly open the mines now lying idle, because the owners are unable or unwilling to undertake the development of their large holdings. Where the leasing system is in vogue the custom mill or smelter is almost a necessity, as leasers are usually practical miners and prefer to leave the treatment of the ores to those who make a business of it.

The system of leasing has a further advantage not to be overlooked. Not only are the leasers usually experienced practical miners, but they are not hampered in their operations by expensive office expenses. It is the general expense at a mine that often makes the difference between profit and loss. Elegant "city offices" maintained at great expense, with a "managing" or "resident director," under large salary, add very materially to the expense of operating. A central general office may be a necessity, but the elaborate and expensive equipment of some of these, and the manner of conducting this branch of the mine's business, are things seldom if ever seen in connection with a leasing proposition. The resident director or manager is sometimes a superfluous individual. If the superintendent or manager is capable, the resident director-manager does not make him more so, and may be an obstruction to the proper and most economical administration of the business of the mine, entirely aside from his salary and expenses.

The leaser works practically, economically and intelligently. What the mine requires in the way of equipment he provides if he can, but manages in some way to supply all that is actually necessary. He generally builds substantially, if not elaborately, and every dollar is made to go as far as experience and good management can make it go. It is not unusual for leasers to work a mine successfully and profitably which failed to pay under corporate management.

CONCENTRATES.

THE line of variation of the magnetic compass moves westward at the rate of four or five minutes aonually.

WHEN tempering a heated drill it should not be held at a state of rest in the water, but moved up and down to secure uniform temper on both tho uppor and lower sides of the drill.

IF MINING PROSPECTUSES were to state all the trutb about evon good mines there would be far less mining done than there is at present. No mine is perfect, but the promoter would not mentioo this fact, much less accentuate it.

CLAYS wbich contain a bigh percentage of iron oxide, lime, magnesia, and various alkalies, fuse much more readily than pure clays. It is also contended that the clay containing coarser grains will stand a higher temperature than those composed of finer grains.

HOLES can be drilled in soft rock, frozen clay, etc., much more rapidly by means of a churn drill than by striking with a hammer or by any machine drill. Tbere is a tendency of material of tbe kind mentioned to cause a drill to "stick" wben not used as a cburn drill.

THERE is no autbentic record of a circular mortar with a singie stamp haviog been used at Sutter Creek, Cal., io 1875, or about that time. Prospectors at various times bave rigged up ingenious crushing devices for milling ricb gold quartz, but as far as known none of tbese makesbift affairs were entitled to be called a mortar.

PURE METALLIC ZINC will last indefinitely in tbe atmospbere. Soon after exposure it becomes coated witb a film of zinc oxide, wbich protects it from furtber oxidation. Its use bas been suggested io tbe construction of monuments and other structures, for wbich purpose it would be more enduring tban marble.

WITH a pressure of 100 pounds at tbe nozzle, 1¾ inch diameter, a stream cao be tbrown vertically 103 feet, and horizontally 96 feet. The nozzle will discharge 574 gallons of water per minute. Witb a bigher pressure, equivalent to a higber head, tbe amount discharged and the distance to wbicb tbe water may be tbrown, will be increased.

THAT a series of samples taken in a mine and assayed is oot always an iodex of the value of tbe ore body sampled may be accounted for in many ways. Usually it is due to the inexperience or lax methods of the one taking tbe samples, or to bis deductions from wbat be considers facts, wbich upon investigation may prove not to be facts at all. The report of similar experience is not uncommon.

CONCRETE steel is concrete reinforced with bars of steel. It is mucb used in construction work. It is supposed to render tbe concrete more firm and durable. It is also known as "ferro-concrete." Concrete built as a facing to masonry often develops a crack between the two as a result of unequal settling. This is the more pronounced if the concrete bas not been tborougbly rammed wben put in place.

BATTERY plates detached from tbe mortar have usually given satisfaction. The table may eitber be built away from tbe lip of the mortar 30 inches or tbereabouts and connected with tbe mortar discbarge by iron pipes, or tbe table may be built on rollers, so tbat it may be moved up to tbe mortar when crusbing, or moved out from it wben cleaning up. The greater number of mills, bowever, bave fixed plates.

FOR tbe purpose of experiment, the managers of the De Beers Consolidated Mines of Soutb Africa filled a vessel with diamonds of various sizes and values, representing tbe "run of mine," and reached the conclusion tbat a cubic meter of diamonds would contain 1,167,000 carats, wortb, approximately, $75,000,000. A yield of twelve carats per 100 loads (1600 pounds) is considered the average yield of the diamond mines.

A HOLE worn through tbe side of a mortar can be repaired by providing an iron plate and securing it to the mortar by means of bolts, placing the plate over the bole. The joint should be made tigbt by tbe use of a rubber gasket. The mortar sbould tben be provided witb liners to prevent furtber wear. Never sbould stamps be allowed to drop in a mortar not provided with dies, not only because of iojury to the mortar, but because good mill work canoot be done in so deep a mortar.

RED OXIDE OF COPPER for various uses in tbe laboratory aod in the arts may be made by precipitation from a solution of copper sulpbate of the metallic copper by means of metallic zinc. Tbe copper falls in minute flakes. During tbe process the solution should he stirred occasionally. The copper is recovered hy filtration and the filtrate dried for two or more weeks, during which time it turns very dark—almost black. Tbis drying and oxidizing process should be stopped at about tbe end of three weeks, and the oxidized copper placed in an air-tight cast iron vessel, io which it is subjected to a red heat for several hours in a reverberatory furnace. This process converts it into a brilliant red oxide. The oxide remains in this conditioo under ordinary circumstances for an indefinite time.

THE cost of mining in Mexico varies as in every other locality with the conditions surrounding the mine. In a general way, when all conditions excepting wages are about equal, it may be said mining can be carried oo in Mexico at a cost somewhat lower than in the United States, owing to the generally lower wages, though Mexican labor is not so efficient as in the United States. Mexico, moroover, is free from the strike nuisaoce tbat is becoming such a marked factor in the expense of mining in the United States.

QUICKSILVER kept in a bottle or other vessel does not evaporate under ordinary temperatures, and it is not necessary to cover the mercury with water or other liquid, but a dilute acid solution is recommended for quicksilver containing aoy impurities, suoh as lead or copper, which are most likely to be found in it, being derived from small pieces of babbitt metal, fragments of copper plates, and the detonating caps used in blasting. When mercury is clean, a dilute solution of cyanide of potassium will tend to keep it brigbt.

LEATHER BELTS are not "always" used io driving dynamos or otber electrical machinery, in preference to rubber belts. Either leather or rubber belts, or ropes, may be used in driving, tbe cboice being largely a matter of convenience. It is preferred to have a considerable distance between tbe driving and driven pulleys, as tbe necessary friotion is obtained not so mucb by tension as by tbe weigbt of tbe belt or rope itself. It is preferable to run with the top side slack, and to make tbe bottom side tbe driviog side, as this gives a large arc of contact.

THE altitude of the City of Mexico is 7606 feet and tbe average annual rainfall is stated to be about 23.2 inches. That at Chihuabua is somewbat greater, being 25 8 incbes. Tbe latter city is at an altitude of 4713 feet. The amount of rainfall at any place cannot be even approximately estimated by tbe altitude, as they bear little relation to eacb otber. For instance, tbe rainfall at tbe city of Cueruavaca, at an altitude of 5186 feet, is 111.9 incbes, and at Oaxaca, at an altitude of 5153 feet, is but 28.6 inches, and at Matamoras is 37.2 incbes at an altitude of 143 feet.

THE rigbt to follow the ore or vein is limited by tbe end lioe, but under ordioary conditioos the vein may be followed downward, on its dip, to indefinite deptb. This is tbe universal rigbt in all of tbe mining regions of the United States, where the mineral lands were originally on the public domain, except at Leadville, Colo., wbere, owing to the form of the mineral deposits, tbe extralateral rigbt is not recognized, as no jury bas yet been impanelled in tbat district wbicb would admit tbat the ore deposits were lodes, and tbe right to follow them on their dip was consequently denied.

GOLD occurs in "soapstone" (steatite) in a number of places in California. The most noted locality is on aod near the Tonzi ranch, 6 miles west of Sutter Creek, Amador county, wbere, along tbe eastern side of a wide serpentine belt, the massive serpentine has been sheared to a schistose condition and is sligbtly gold-bearing. The serpentine, tbough not really talc (soapstone), is so closely allied to that mineral that the two are essentially the same. Several attempts have been made to treat tbese gold-bearing soapstones, but witbout financial success. The gold is extremely fine, occurring in sbeets like gold leaf, and rarely in grains. Investigation of these deposits does not indicate tbat they are commercially valuable.

IN SHAFT SINKING a bucket is generally preferred to a skip for the reason tbat a bucket can be easily moved about on tbe bottom of the sbaft to accommodate sbovelers. A low skip is usually convenient in a tbree-compartment shaft wbere tbe sinking is done in the middle compartment, even tbougb tbe skip must remain on the track, and cannot be shifted about like a bucket. It is a mistake to reduce tbe size of the manway and pipe compartment to small dimensions for reasoos of economy. Tbis compartment should be tbe largest in tbe sbaft, in order to afford room for workmeo wbo are obliged to bandle pipes, pumps, etc., and wbere tbis compartment is also used for boisting it sbould he somewhat larger tban tbe other compartments.

THE Supreme Court of the United States (case of Tartar vs. Spring Valley M. Co.) decided—and it has since generally been held throughout tbe Pacific coast States and Territories tbat "the right to water by prior appropriation for any useful purpose was entitled to protection. Water is diverted to propel macbinery in flour mills and saw mills, and to irrigate land for cultivation, as well as to enable miners to work tbeir claims; and in all sucb cases the right of the first appropriator, exercised within reasonable limits, is respected and enforced." The party who first appropriates the water of a stream for mining purposes obtaios the rigbt, hotb as to parties who attempt to take it by tapping the stream above, or who need it in the stream below. A homestead or other entry is subject to rights of a prior locator of water. Tbe location of the water should be made, the ditcb line staked and work commenced and prosecuted with reasonable diligence. If the notice and record are not followed up within reasonable time by actual work in carrying out the intended appropriation they amount to absolutely nothing. What a reasooable time is may have to be determined by the courts, but it is generally presumed to meao a sufficient timo to enable the locator to get his tools and men on the ground and begin actual work.

THE habit of feeding quicksliver in givon amount at stated intervals regardless of the value of the ore is a pernicious one and should never be adopted by young mill men who desire to make a success of milling. An ore may average about the same value from month to month, but there is always a daily and often ao hourly difference io value of almost any ore. The condition of the outside plates should determine the time and amount of quicksilver to be fed. Rarely ao oro is found wherein tbe values are regular, and with these the mill man is safe, but ordinary practice requires that the battery man must keep awake and watch his plates constaotly. The mill wbere the battery man can find nothing to do is either crushing very poor rock or the mill foroman sbould be engaged in some other kind of employment.

LACCOLITE is a name derived from the Greek meaning cistern. It was first applied by G. K. Gilbert to those peculiar intrusions of igneous rock injected into sedimentary strata, but wbicb did not reach the surface until exposed by erosion. Tbe first occurrence of tbis character to be described was in tbe Henry mountains in soutbern Utah. There are numerous laccolites in Utah Nevada, Colorado and the Black Hills of Soutb Dakota. The fact tbat laccolites frequently are accompanied by valuable ore deposits is of interest, particularly tbose of tbe San Juan country in soutbwest Colorado, tbose at Leadville and some of those in Soutb Dakota. It bas been noticed, however, tbat tbe ore deposits are more directly associated with dikes wbicb intersect the sedimentary rocks and laccolite sheets as well. Tbe material forming laccolites is not always tbe same, but is usually an acid rock.

ALABASTER is a compact variety of gypsum, of earthy appearance, sometimes faintly tinged witb color, as pink, yellow or greenisb. It is sometimes used for ornamental purposes, being carved into various imitative shapes. Gypsum is used for fertilizing purposes and is known as land plaster. Calcined and ground, it forms plaster of Paris used as a "bard finisb" for walls and ceilings of houses, also in tbe construction of various ornamental pieces for structural work. In recent years large amounts of "staff," a material largely employed in the construction of temporary buildings, sucb as are built for exposition purposes, has been made from gypsum. Tbe amount of gypsum produced in the Uoited States is about 700,000 sbort tons aooually, worth approximately $2.50 per ton. The situation of a deposit and local demand for tbe material are the principal considerations io determining tbe value of a deposit of gypsum. One of the largest concerns handling gypsum is tbe United States Gypsum Co. of Omaba, Neb. They bave works in Nebraska, Iowa, New York, Michigan and Oklaboma.

GLASS is made essentially of silica (quartz sand) as an acid element; soda or potash as an alkalinc base, and lime and oxide of lead as the alkaline earths. To the alkaline eartbs commercially employed tbere sbould also be added baryta and alumina, tbe former in place of lead, and the latter a common ingredient in certain kinds of glass. The composition of window glass is purified quartz sand, 100 parts; chalk or limestone, 35 to 40 parts; sulphate of soda, 40 to 45 parts; cullet or waste and broken glass, 50 to 150 parts. These are mixed before charging ioto the pots. To make colored glass various oxides of the metals, iron, manganese, gold, arsenic, copper, cbromium, uranium, cobalt, etc., are added in greater or less amount to tbe cbarge. Tbe amouot of metallic oxide and tbe lengtb of time tbe charge remains in tbe furnace determines the color of glass. Cobalt produces a blue color; uranium makes yellow glass, also salts of silver and antimony oxide; a peculiar yellow is produced by tbe addition of powdered cbarcoal to tbe cbarge; cupric oxide produces green, and manganese oxide violet. An excess of manganese produces black glass.

THE most reliable method to determine tbe steam consumption of an engine is to make an evaporation test; that is, to measure tbe water fed to the boiler in a given time and delivered to the engine in the form of steam. Tbis method, however, entails considerable trouble and expense. So engineers often figure out the water consumption from indicator diagrams. The terms water coosumption and steam consumption are here used indiscriminately, for a pound of water will produce a pound of steam at any pressure. Figuring that way can never be wbolly accurate, because tbe data requisite to insure results are not thus procurable. That is, the amount of water accouoted for by tbe indicator is always considerably less than it ought to he because of cylinder condensation, valve and piston leakage, to tbe extent that it might be that only 50%, or at best not more than 90%, of the water passiog through the cylinder would be accounted for by the indicator. But if the cylinder were properly steam jacketed, or if superbeated steam were used, and there were no leakage of steam from valves or pistons, tbe water consumption could he closely calculated from an indicator diagram.

Secondary Enrichment of Mineral Veins in Regions of Small Erosion.

Written for the MINING AND SCIENTIFIC PRESS by C. L. HERRICK, Ph D.

In the rapidly growing but still very unsatisfactory literature of mineral deposition it appears to the writer that one element of very great importance has been nearly entirely overlooked.

The question has often been asked why there should be so marked a difference in the reliability of gold-bearing veins found in two parts of the same range, as, for example, the Rocky mountains of Colorado and the same range farther south. It can not be denied that, with essentially identical conditions of country rock and vein filling, the veins of New Mexico and Arizona have a greater tendency to exhibit a falling off of value in depth and a greater variability near the surface than do those of the northern regions.

Without entering into any comparison of the several regions, the writer hopes to present a working hypothesis which is based on a sufficiently wide range of observation to be at least of practical value and to form the basis for further discussion. While the fact above alluded to will be questioned by some New Mexico mining men, who will in the same breath admit it by appeal to much-used statement that in New Mexico there have been few, if any, attempts to reach adequate depth, yet we will admit, for the purposes of this discussion, that the gold ores in New Mexico are more fickle in distribution, and the mineral veins are less reliable in depth than farther north.

Practically all gold-bearing veins in this region are either found in andesite, or other basic rock, or are in such geological association as to indicate that the fissures passed through such intrusives. The sequence in the Territory and southern Colorado has been, first, andesite and allied porphyries; second, trachytes and trachyte pitchstones, etc.; third, acid rhyolites, with free quartz, and often of almost granitic appearance, grading into acid glasses and obsidian; fourth, recent basalts and basaltic tufas, the last mentioned being Post-Tertiary. In none of the above, except the first, are mineral-bearing veins of first intention found, though cases exist where a gold quartz vein passed through an andesite into a rhyolite.

It is known that the andesite is later than the Permian, for there are found numerous instances where larger or smaller fragments of granite, Carboniferous limestone and Permian sandstone are incorporated in the brecciated phases of the andesite. It is also well known that the andesite flows are multiple and that the earlier andesite is often incorporated in the latter along contact zones, and the andesite is prone to be greatly shattered and badly mended by successive outbursts.

The quartz veins are frequently much disturbed and displaced by faults within the andesite. It becomes a very difficult question in these cases whether the quartz veins were in situ and have been displaced by the faults, as ordinarily supposed, or whether the faults laid open the rock and the infiltration conformed to the several sets of fault openings. It is the writer's opinion that the latter possibility is often overlooked. For example, in a gold vein which the writer has opened for several hundred feet, where both walls are of andesite and the vein is upon the average over 5 feet wide, an intrusion of one wall, obviously due to cross faults, causes a "pinching" of the vein to a mere crevice with quartz filling. Beyond a second cross fault the vein resumes its original width and character. It is fairly obvious, in such a case, that the intrusion of the foot wall was brought about before the filling of the vein by quartz.

On the same vein an entirely similar cross fault throws the vein laterally some hundreds of feet. The cross fault is sharp and the wall is smooth and appears "slickensided," though, it must be observed, what miners call "slicks" in clayey ground, are generally of water origin. The quartz is 4 to 6 feet wide at the break and stops sharply. One would say that this is a clear case of throw of quartz vein by faulting of the country rock. There is, however, a rib of good quartz carrying good values in the slip passing toward the continuation of the vein in the direction of throw for some distance. We might suppose that this quartz is secondary and has been deposited since the faulting of the main vein, but it has none of the appearance of such segregation quartz and is quite like the original vein in appearance and value. It is not banded nor ribboned, as segregation quartz here tends to be.

It appears to the writer more probable that the longitudinal and the transverse fissures were both prior to the quartz filling, and that the quartz along the transverse fault is contemporaneous and similar to that of the main vein. Often the recognition of such a possibility will have a practical bearing on the method of mining exploration. It will not be certain that the vein when found beyond the cross fault will be of the same width or value as at the point of apparent fracture, while on the usual hypothesis that conclusion would be inevitable.

It has been the writer's privilege to study in a practical way the characteristics of the quartz veins in a region where the andesite forms the country rock over a large area and is broken, as above described, without the intrusion of any other volcanic or igneous rock and at a distance from any known stratified rock. The region is gently rolling and has escaped even the moderate erosion of the mountainous parts of New Mexico. The quartz veins at a depth of over 200 feet are massive and homogeneous, and fill the space of the vein from wall to wall without gangue or clay. The wall selvage is narrow and obviously a reaction product between andesite and quartz. Values are chiefly oxidized at this depth, though covered by 100 feet of surface water, which is obviously in circulation or movement toward the drainage axes.

Ascending to a point 100 feet below the surface, the vein preserves the same (or greater) width, but the quartz is reduced to one-half, and the space remaining is filled with a mixture of decomposed quartz and clay or gangue. The loose part of the vein often carries values, but the occurrence of gold is sporadic. On the whole, the value in the vein where it is all quartz and where it is half gangue may remain the same, with such exceptions as will be noted beyond. At or near the present water level, and for some distance below, there is some concentration of value. Above the water level to the surface there is a tendency for cross fissures and fault planes to make shoots of richer ore in the vein, and the surface is often better value than 50 feet lower.

At the line separating the loose upper zone from the compact lower quartz there is frequently a belt of spongy quartz of high value running many hundreds of dollars per ton. The work has not been carried to such a depth as to explore the unoxidized zone, though there are some bunches of sulphides in the lower quartz. On the other hand, the country rock adjacent to veins and at fault planes is often densely impregnated with pyrites of small value.

It may be noted that this region has suffered little denudation. In central New Mexico only one locality has yielded any evidence of small local glaciers. The erosion has been by way of atmospheric disintegration and surface erosion by local waters. The area is one uncompromised by mixed intrusives, and the conditions have been simple.

Water obtained access to the fissured quartz of the veins and the ores have been oxidized to an unknown depth. The water, being in movement, has conveyed air to the deepest portions yet seen. The contact action between acid vein matter and basic country rock has been profound, and resulted in extracting kaolin and decomposing feldspars from the andesite. The lime from the feldspar has been collected in fissures not filled by quartz, and the result is that the more recent fissures are filled with lime, quartz and iron carrying very good but variable gold values.

The quartz has suffered to a considerable extent and has been fissured and honeycombed. By this double process the vein has been widened and part of the fissure filled with gangue of the mixture just described. In this more or less of the gold from the decomposed quartz remains. At and near the surface is a zone of enrichment, due to the infiltration of heavier materials from above. The iron has largely been changed to red oxides or entered into ochraceous combinations. In the quartz the change has proceeded no further than magnetite.

It seems reasonable to suppose that from the upper zone of enrichment down to the less altered zone of massive quartz there would be an impoverishment by which this quartz would be robbed to supply rich pockets or belts at the point where the free circulation is checked.

Thus simply are all the phenomena described to be explained. The processes here illustrated may have occupied a very long time, and the only effect of the glacial period is the indirect one, in so far as it may be true that the differential strains due to unequal weight of ice gave rise to the fissuring producing the recent basaltic flows.

The period of basaltic overflow was one of profound faulting, and it is very possible that even in districts not in immediate contact with basaltic flows or volcanoes the effect was felt in fracturing by shearing strains so produced. In the locality here alluded to there are basaltic necks and sheets at no great distance.

Contrasting such conditions as are here described with those in a region of glacial denudation or excessive erosion from other causes, the difference is very apparent. In most of the latter instances all that has so far been brought to view in our region is absent, and there remains but a zone of superficial enrichment, immediately following which is the sulphide zone. In some cases the sulphide zone is covered by "cap," in no way comparable to our surface zone.

The practical question then remains: Is it probable that the unoxidized zone will prove to have values sufficient to pay for the cost of sinking as much as 1000 feet? Each investor will answer according to his own light. If he is convinced that the massive quartz carries the equivalent of the value of the sulphide quartz below it, he will be governed by this value. He may believe that the oxidized quartz has all suffered impoverishment, as part of it has demonstrably done. In any event, he is justified in assuming that veins of good size and constancy will go down as far as he is able to follow them, and that sooner or later he will reach a region where he can expect uniformity and permanence of value. The ore will be concentrating material, and in most New Mexico camps will have few detrimental elements.

It is to be hoped that some one will be found with courage and means to explore these attractive depths, who will not be turned aside by the easier dollars in the surface pockets of the same veins.

Considerations Favorable to Hot Blast Smelting.*

In blast furnace smelting of gold, silver, lead and copper ores, conditions at the incandescent zone above the tuyeres for oxidation and reduction are controlled by volume, temperature and pressure of blast with reference to cross section of the furnace at the tuyeres, character of the material being operated upon, and end results to be accomplished. In the use of hot air, provision must be made in tuyere area to accommodate and allow the passage of its vastly expanded volume. If the air pipes and tuyeres are not proportioned to it, then necessarily at a given pressure of blast there may occur a localization of combustion simply by reason of the limited amount of oxygen supplied through them, which at once combines with the first carbon or other fuel with which it comes in contact, leaving less or none for other fuel in the same zone and above.

Heating air blast by reason of its increased volume tends to facility of distribution and not to localization of combustion. Pure oxygen blown in at the tuyeres would produce most violent local combustion and intensest heat. Nature attenuates oxygen by the admixture of a trifle more than four times its volume of nitrogen and the product becomes air and is susceptible, physically, by well-known means, of a much wider distribution and contact with the material and a corresponding distribution of resulting combustion in the tuyere zone. Increasing heat invests it with the property of accelerating energy and intensity which would tend, if blown in hot, to violence of reaction with carbon, sulphur, iron, etc., concentration or localization of combustion and resultant excessively high temperature, were it not for the counteracting factor that nature again provides in the expansibility of gases under heat which has the same material effect of an attenuating or thinning down of the air by increasing its volume by expansion, components remaining unchanged, the increased energy of its oxygen by reason of heat being counteracted or compensated for by reason of its attenuated condition in expanded volume, and hence facility of distribution prevents undue local action. The reactions peculiar to the zone of fusion do not, however, occur until the air blown has reached the temperature of that zone and the oxygen has hence acquired its extreme energy, therefore the effect of heating the blast on the action of the furnace is to make uniform action possible where it enters the furnace, by eliminating much of the cold otherwise carried in by the air blast and circulated or distributed irregularly and without control. A given amount of air expanded by heat to three times or four times its original volume is distributed throughout the tuyere zone through the pressure imparted to it by the blowing engine, with facility and certainty proportional to its expanded volume.

Hot wind does not necessarily tend to concentration of temperature and rapid smelting, though it makes either the one or the other, or both possible, when pressure, temperature and volume are under control to adapt all to size and to shape of furnace and charater of ore being smelted. Intense heat is a necessary condition of smelting zone of a furnace. Cold, purely as cold in the air blast introduced for the purpose of producing any useful modifying effect on a zone of the furnace where incandescence is a normal and necessary condition, is an absurdity. The effect of such cold can only have a retarding and unfavorable influence in that zone.

A part of the air sent to a blast furnace is for the purpose of generating heat by the burning of fuel to raise the temperature of material within the furnace to a point at which it is possible for the desired chemical reactions to take place rapidly, and further to melt such material when it reaches the tuyere zone, while another part is required for the oxidizing of fuel necessary for those reactions, or else for its oxidizing effect higher up in the furnace on ores carrying sulphur, iron, etc. There are large proportional areas, especially in the neighborhood of the tuyeres, in every cold blast furnace, in which the desired reactions cannot take place because the blast of cold air keeps these areas too cool to admit of them. Proportionally as the air is sent hot into the furnace these cool areas are reduced in size and in far greater proportion is the capacity and efficiency of the furnace increased. Zinc crusts and other accretions of kindred nature obtrude less difficulties to combat when not complicated by the presence of cold inactive spots produced by the cold of the air blast.

*Abstract from pamphlet issued by the Colorado Iron Works Co., Denver, Colo., entitled "Some Details as to Smelting Practice and Equipment."

A pound of carbon requires 11.6 pounds of air for its consumption, and conversely for each pound of carbon that is saved from burning it in the furnace by burning it in contact with the blast before it reaches the furnace, the cooling influence of 11.6 pounds of cold air is kept out of the zone of intensest heat, as much cold in the air blast to be overcome by heat to be developed from each pound of carbon as would be required to melt thirty-two pounds of pig iron from atmospheric temperature, and it is by far better to relieve the furnace of at least a part of the duty of heating in its most vital part such enormous quantities of cold air to burn fuel for the production of heat that may more efficiently and cheaply be produced outside and carried in with the air blast.

If the current of cold air could be kept constantly impinging on the glowing coke, then to overcome its cooling influence would be only a question of fuel added; but it is not so, because such incandescent fuel as a sharp blast of cold air is caused to impinge against is at once cooled, blown out as it were, and it is only after the blast of cold air has passed through the heated mass of material and becomes heated thereby that it may impinge directly upon incandescent fuel without deadening or cooling it. This is plainly seen in the operation of any cold blast furnace, for on looking into the tuyeres they are generally seen to be black and to look cold throughout, except that far in an occasional bright spot may be seen, but such bright spots are always protected from the direction of the cold blast by the cooled or partially cooled material at the tuyeres against which the air impinges on its entrance to the furnace, and thence finds its way around through the heated mass of furnace material and becomes itself heated and thus prepared to perform its functions in the necessary reactions.

And so it turns out that in the absence of a heating stove outside the blast furnace in which the air blast may be heated, the furnace itself at its most vital and most sensitive part—the tuyere zone—must be utilized as a stove for that purpose primarily and at the expense of its efficiency for its other duties and functions.

In cold blast furnaces there is a constant tendency to burn too high up above the tuyere zone, which is caused by the cold air cooling relatively all material at the tuyeres, while itself is being heated up to the temperature at which it is possible for the air to become a factor in the reactions to which it is necessary.

If in any particular zone of the furnace a given condition of temperature, oxidation of fuel and incandescence is necessary, then that condition is desirable in the whole of that zone, and the cooling in spots and patches by forcing a blast of cold air into it curtails the area and the efficiency of that zone, not only by the amount in relative proportion of those abnormally cooled spots or patches to the whole zone under consideration, but by far more than this, for they lie there in the way of the blast, obstructing and preventing it from circulating freely throughout the incandescent zone, which it necessarily should do, for the requisite supply of oxygen to each and every individual inch in that section. Not only is the room that such cooled areas occupy lost absolutely, and to be deducted from value of cross section, but their adverse effect on its operation by deflecting the blast upward or downward anywhere away from where it is needed to where it is not needed is still more serious, for no possible good, but much harm, must come as a result of blast blown against cooled masses of furnace material and deflected thence upward or downward or athwart into material from which heat is obstructed by the cool areas. Whenever the furnace is so large that blast pressure must be increased to several pounds in order to permeate to the center of the whole mass of furnace material at the tuyere zone to maintain combustion there, then the excess of cold extinguishes the fire, blows it out, as it were, in continually widening areas in the neighborhood of the tuyeres where it is introduced and for distances inward greater and greater as blast pressure is increased, but in patches or spots only, of greater or less area until the center is reached and cooled so much as to stop the smelting operation all along the center line. The half melted mass of unsmelted material cools more and more, growing larger and larger until it is finally connected here and there with the cold patches between the center and the sides, and now excessive irregularities are culminating in a frozen up furnace, often solid at the center, while yet partially open along the sides.

Air is delivered into a blast furnace at its hottest part—the zone of fusion—the tuyere zone. It follows that to perform its functions its temperature must first become the same as the temperature of that zone, possibly 4000° or more, oxidizing rapidly any reduced lead with which it may come in contact. Another part landing against some cold dark spot and deflected thence against some other cold dark area, thence dodging around until it does get into the heat somewhere, often far above the proper smelting zone, and having finally acquired the heat necessary, it performs its offices in conjunction with fuel at that point, producing heat and setting up a temporary smelting area above the normal one. Thus is the proper smelting zone robbed of a part of the air necessary to its appropriate reactions and further chilling ensues, while the smelting zone is extended upward and rendered inefficient throughout its whole extent.

Hot blast contributes to support the combustion of carbonaceous and other fuel, as sulphur, etc., with a minimum of oxygen supplied, i. e., the hot blast and fuel are drawn upon most for the necessary smelting reactions, and least possible for heating per se. Heating the blast promotes regularity of heat and of chemical reaction by promoting uniformity of conditions throughout each individual section of the furnace, especially in the zones of incandescence and fusion where the most active changes are taking place, reduction or oxidation predominating, as the case may be, both in that zone and above. Because the blast is heated it does not follow that the furnace need be, or would be run hotter than is common or desirable. Hot blast does not necessarily involve increased temperature in any one zone of the furnace. Incandescence at the tuyere zone, where the air blast enters, is a necessary condition of every blast furnace; but the temperature of the heated blast being always below that of incandescence, the heat of that zone and of the whole furnace is within easy and accurate control.

In matte smelting of sulphide ores that require previous partial roasting, and where carbonaceous fuel is used, the tendency is to reduce iron oxide and sulphurous acid gas by excess of carbon monoxide and to produce poor matte, because carbon monoxide in the first instance robs the FeO of its oxygen to form carbon dioxide, thus robbing the slag of the iron needed there and sending it to the crucible to burden the matte, and in the second instance the sulphurous acid gas, which would otherwise escape by the chimney, is robbed of a part of its oxygen, thus producing sulphur and sending that also to the matte. The less carbonaceous fuel necessary to be burned in the furnace, and the less carbon monoxide generated there (other conditions being right), the less imminent become these undesirable reactions, and hence the more of the necessary heat that is generated outside of the furnace and sent in with the air blast, and so the less carbonaceous fuel necessary, the more favorable are the conditions in this view of the case to a higher percentage of concentration of valuable products in the matte, and the suggestion points significantly to pyritic smelting.

To the application of hot blast is due the great economy and efficiency realized in modern iron smelting practice, for it is the application of heated blast that has made the great iron furnaces of to-day possible. Blown with cold blast, not one of them could run a week. Heated blast, making uniform conditions of combustion and of consequent reactions possible in each individual cross section of the furnace, has made high blast pressure possible, without which furnaces of large cross-section area could not be blown.

The air blast in iron smelting is heated by the inflammable gases, chiefly the carbon monoxide which is evolved. Little or no such gases escape from furnaces smelting the ores of copper, lead, silver and gold, and hence to heat the air blast for these other means must be resorted to.

The importance of this feature is manifest when it is considered that 11.6 pounds of air is consumed in burning one pound of carbon, as coal or coke. More than one and one-half ton of air must be heated to the smelting temperature either in the blast furnace or both in the stove and in the blast furnace for each ton of ore and fluxes smelted.

As indicated by the above explanation, the greater proportion by far of the heat involved in the smelting of ores is expended in heating the air necessary to the operation, either within the blast furnace, as when cold blast is used, or partly by the stove and partly within the smelting furnace, as when hot blast is applied.

Desulphurizing Slimes by Heap Roasting.*

NUMBER II.—CONCLUDED.

Written by E. J. HORWOOD.

The width found most suitable is 22 feet at the base, the sides sloping up rather flatter than one to one, with a flat section on top reaching 7 feet in height. As there is always 6 inches of the outer crust imperfectly roasted, it is advisable to make the length as great as possible, thus minimizing the surface exposed. The company is building heaps up to 200 feet long.

During roasting, care is required to regulate the air supply, the object being to avoid too fierce a roast, which tends to sinter and partially fuse the material on the outer portions of the lumps, while inside there is raw slime. By extending the roast over a longer period this is avoided and a more complete desulphurization is effected. Experiments conducted by Mr. Bradford, chief assayer, demonstrated that, at a temperature of 400° C., the sulphide slime is converted into basic sulphate, while at a temperature of 800° C. the material becomes sintered, owing to the decomposition of the basic sulphate and the formation of fusible silicate of lead.

In practice, the sulphur contents of the material, which originally are about 14%, become reduced from 6.5% to 8.5%—half in the form of basic sulphate and half as sulphides; much of the material sinters and becomes matted together in a fairly solid mass. The heaps are built without chimneys of any kind; a strip about 5 feet wide along the crest of the pile is left uncovered by plastered slime, and this, together with the open way in which the lumps are built in, allows a natural draught to be set up, which can be regulated by partly closing the open ends of the flues at the base of the pile. Masonry kilns were used in the earlier stages with good results, which, however, were not so much better than those obtained by the heap method as to justify the expense of building, taking into consideration, too, the extra cost of handling the roasted material in the necessarily more confined space.

Much interest has been taken in the chemical reactions which take place in the operation of desulphurization of these slimes, it being contended on the one hand that the unexpectedly rapid roast which takes place may be due to the sulphide being in a very fine state of subdivision, and more or less porous, thus allowing the air ready access to the sulphur, producing sulphurous acid gas (SO_2). On the other hand, others, of whom Mr. Carmichael is the chief exponent, claim that several reactions take place during the operation, connected with the rhodonite and lime compounds present in the slimes, which he describes as follows:

"The temperature of the kilns having reached a dull red heat, the rhodonite (silicate of manganese) is converted into manganous oxide and silica; at a rather higher temperature the calcium compounds are also split up, with formation of calcium sulphide, the sulphur being provided by the slimes. The air permeating the mass oxidizes the manganese oxide and calcium sulphide into manganese tetroxide and calcium sulphate, respectively, as shown as follows:

$$3\,MNO + O = MN_3O_4$$
$$CaS + {}_4O = CaSO_4$$

And, as such, are carriers of a form of concentrated oxygen to the sulphide slimes, with a corresponding reduction to manganous oxide and calcium sulphide, as shown by the following equation, in the case of lead:

$$PbS + 4\,Mn_3O_4 = PbSO_4 + 12\,MnO$$
$$PbS + CaSO_4 = PbSO_4 + CaS.$$

The oxidation of the manganous oxide and calcium sulphide is repeated, and these alternate reactions recur until the desulphurization ceases, or the kiln cools down to a temperature below which oxidation can not occur. These reactions, being heat-producing, provide part of the heat necessary for desulphurization, which is brought about by the following concurrent reactions between metallic sulphates and sulphide:

"The first that probably occurs is that in which two equivalents of the metallic sulphide react on one of the metallic sulphate with reduction to the metal, metallic sulphide and sulphurous acid, as shown by the following equation in the form of lead:

$$2\,PbS + PbSO_4 = 2\,Pb + PbS + 2\,SO_2.$$

"The metal so formed, in the presence of air, is oxidized, and in this state reacts on a further portion of the produced metallic sulphide with an increased formation of metal and evolution of sulphurous acid, according to the following equation, in the case of lead:

$$2\,PbO + PbS = Pb + SO_2.$$

The metal so produced in this reaction is wholly reoxidized from the oxygen of the air current, and, being free to react on still further portion of the metallic sulphide, repeats the reaction, and becomes an important factor in the desulphurizing of the undecomposed portion of the material. As the desulphurization proceeds, and the sulphate of metal accumulates, reactions are set up between the metallic sulphide and different multiple proportions of the metallic sulphate, with the formation of metal, metallic oxide, and evolution of sulphurous acid, as follows:

"With two equivalents of metallic sulphate to one equivalent of metallic sulphide, in the case of lead, according to the following equation:

$$PbS + PbSO_4 = 2\,PbO + Pb + 3\,SO_2$$

"With three equivalents of metallic sulphate to one of metallic sulphide in the case of lead, according to the following equation:

$$PbS + 3\,PbSO_4 = 4\,PbO + 4\,SO_2."$$

The volatility of sulphide of lead—especially in the presence of an inert gas such as sulphuric acid—being greater than that of the sulphate, oxide or the metal itself, it might be thought the conditions are conducive to a serious loss of lead. This, however, is reduced to a minimum, owing to the easily volatilized sulphide being trapped as non-volatile sulphate, by small portions of sulphuric anhydride (SO_3), which is formed by a calalytic reaction set up between the hot ore, sulphuric acid and the air which is passing through the mass. Owing to the non-volatility of the silver compounds in the slimes, the loss of this metal has been found to be inappreciable. The zinc contents of the slime are reduced appreciably, thus rendering the material more suitable for smelting. After

*Abstract Trans. Australian Inst. Min. Engrs.

desulphurization ceases, a few days are allowed for cooling off. On the breaking up of the mass for despatch to the smelters, as much of the lower portion of the walls is left intact as possihle, so that it can be utilized for the next roast, thus avoiding the rebuilding of the whole of the walls.

Before concluding, I wish to acknowledge my indebtedness to Mr. Carmichael for his assistance in the technical portion of this paper, which I trust will prove to he not without interest.

Drying of Peat.

Written by C. O. BARTLETT.

The question of drying very many different kinds of materials, such as concentrates, coal, sand, clay, marl and all similar suhstances is getting to he a very important factor in the manufacture of products using two different materials; for instance, the manufacturer of cement first wishes to reduce his clay or even crushed stone to an even moisture, so that he may know exactly what he is using. He wishes to dry to a certain degree or per cent of moisture so that the material is always the same. For instance, clay will vary all the way from 15% to 30%, according to weather conditions; coal will vary according to weather conditions from 5% to 15%; the same may he said of sand. It is very seldom that sand or coal will contain 15%, hut there are times after a very severe rain storm that the rain will get frozen into ice after having impregnated the coal, causing an excessive degree of moisture as high as 15%, and the same can be said of sand.

Almost any kind of material can he dried. The question is, What will it cost to do it? For instance, we have an inquiry to-day for the necessary machinery for drying distillery slops. Now, this material contains at least 90% moisture. That it can be dried there is no question, but the cost of drying it will be more than the worth of the material after it is dried. For instance, you commence with ten tons and take out nine tons of water, which leaves one ton, and the result is that the cost will he more than the material is worth.

We lately had an inquiry for drying peat in large quantities. In fact, we are getting these inquiries right along. A person wants a dryer for drying 100 tons of peat an hour, containing 80% moisture and reduced to 5% or 10% moisture. Now, this means that starting in with 100 tons of peat you have a finished product, after taking out at least 75% moisture, of twenty-five tons of dried peat, and the cost of drying depends almost entirely upon the amount of water to be evaporated, and peat being a cheap material, the cost of taking out 80% will amount to about all the finished product is worth. This is especially true of peat, for the reason that it being of a combustible nature, must he handled with care and will not allow too great a heat, which means a greater cost of drying.

We generally calculate that one pound of good hituminous coal, or its equivalent used for fueling, will evaporate from eight to ten pounds moisture. Therefore, to dry 100 tons of peat, containing 75% moisture, means to dry out seventy-five tons of water, and allowing one pound of coal for each ten pounds of peat. equals no less than 7500 pounds of coal to dry it. Of course, the peat is an exception; that is, heing of a spongy nature, contains a very large amount of water. Taking sand or concentrates, the amount of moisture would run on an average from 8% to 10%, and in drying five tons an hour and allowing one pound of coal for every ten pounds of water evaporated would mean 1000 pounds of water, which would require only about 100 pounds of coal, and the cost of drying is very small. Same may be said of drying coal. But whatever is dried, the cost of drying it will depend largely upon the amount of water to he evaporated. Now comes the different kinds of driers, which we will class into three kinds:

First—Direct heat. What we mean by direct heat driers is where the heat or fire is applied directly under material to be dried, and the rotary drier is usually used for this purpose. The material to be dried is placed in at one end of the drier and a fire similar to a fire under a boiler is made directly under it which heats the product to an intense heat, causing it to dry rapidly. If the products of combustion will not injure the material to he dried by coming in contact with it, they can be passed first underneath and around the drier and afterwards through the material being dried, reducing somewhat the cost of drying, for the reason that you get a little hetter results; that is, you get all the heat that there is in the coal you are using. On the other hand, materials like peat and some kinds of clay and sand would not allow the product of combustion to pass through the material, then the drying must all be done from the outside, and the cost of drying increased accordingly.

Second—The next style of drying is to first heat the air, either with a coil of steam pipe or with direct heat, and then pass this heated air through the material to he dried. This method is frequently used in drying salt. I distinctly remember of fitting up a small cheap drier like this for a certain chemical company for drying what I call epsom salts. They were having great trouhle in drying them and had put in a large amount of steam pipe with shelving over the pipes, and then placed the salt on these shelves to be dried, but with very poor results, for to dry economically it is necessary to keep the material moving, and I simply took a large common stove, encased it with a sheet iron casing, leaving a place open for firing and taking out the ashes. The common stove made a great deal of heat, which was radiated into the chamber or oven, as you might say. The material to be dried was placed in a common wooden cylinder ahout 36 inches in diameter and 16 or 18 feet long, with rihs for elevating the material up and dropping it down. The heat was taken from this oven with a fan and passed through the cylinder in which the salt was placed. It was a great success and they are using this same system to-day.

Third—Steam drier. The steam driers are very essential in some places, although not so economical as direct heat, for the reason that steam pressure of seventy-five pounds gives only about 300° heat, and 100 pounds gives 330° of heat, and this is inside of the cylinder, which means considerahle less temperature on the outside, where the material to he dried must necessarily he. Therefore, steam pressure cannot he as economical as direct heat. Another great danger in steam driers is that the least particle of a leak is a very serious ohjection, as it is somewhat difficult to make a steam drier hut what is liahle to leak somewhere, especially after years of constant use. The continual contraction and expansion of steam chamhers of all kinds and makes is very severe on joints, rivets, etc., and only with the very hest and most careful care can slight leaks he avoided.

Chlorine Smelting, With Electrolysis.*

NUMBER II—CONCLUDED.

Written by JAMES SWINBURNE.

As to cost of the process, the first thing to realize is that it smelts for all the metallic contents of the ore, not for one only; that all the metals are completely extracted. There is no waste hy fumes or imperfect extraction, and there is no slag. The gangue looks like river sand. There is no room for loss. All that comes into the works is ore and electrical energy; all that goes out is pig metal, sulphur, gangue and oxides. The chlorine goes round and round. There is no room for appreciahle waste of chlorine either. A leak that would show in the halance sheet would make the works uninhahitahle. There is, however, a trace of chlorine in the iron oxide, as it is apt to contain a little oxychloride. There is also a loss in collecting the hydrochloric acid from the hoiling down of the zinc chloride. A little chlorine must therefore he added to the stock. This can be done hy buying crude zinc chloride, or galvanizing pickle, or precipitating calcium chloride with zinc sulphate. In out-of-the-way places it is much simpler to huy zinc chloride, as it is more portahle than hydrochloric acid.

It may he said that a process for such a prohlem must he a maze of chemical operations. This is not the case here at all. The process has only three simple stages: Transforming sulphides into metallic chlorides and sulphur; substituting zinc for all the other metals in the metallic chlorides; electrolyzing out the zinc and recovering the chlorine.

Compare this with ordinary metallurgy. To describe the metallurgy of a single metal at all adequately requires a book. Try and explain even most superficially the metallurgy and refining of argentiferous lead, zinc and copper to anyone quite new to the suhject in the few pages here devoted to description, and it will he seen how simple the new process is. Add to the description of the metallurgy of these metals an account of the refining of copper and zinc and refining and desilverization of lead, and even then you have only half done. To make the comparisons equable, you must give an account of the concentration and separation of refractory ores, and give a description of methods for dealing with a mixed ore of lead, zinc, silver, iron and copper. There can he no doubt that though the steps in the new process sound unfamiliar to ordinarily trained metallurgists, it is in comparison ludicrously simple. But there is even more than this: The new process treats ores, whose smelting by ordinary processes cannot be described, even with unlimited complications, because they are at present untreatahle.

As to costs, everything depends on what ore is used and where it is used. The most ohvious course is to work on refractory ores which are otherwise valueless, but leave large metal contents. The cost of the ore delivered at the works is then known. Thus even in England blue-stone ore can be hought and delivered at from £2 10s to £3 a ton, ready for running into the transformer. The metal content is £8 16s, taking zinc at £20, lead at £12, and silver at 2s. If higher prices can be maintained for pure metals, of course the content must be taken at a higher value. This figure includes all valuahle contents.

The cost of the intermediate process is difficult to state, as it is a question of locality and labor. The capital in this part of the process is small, hut in the estimates heavy allowance has heen made for deterioration and all other contingencies. On the other hand the conversion, which alone is a new sort of chemical experience, is extremely simple and easy. The intermediate processes depend on the ore. Thus, if there is no copper, part is cut out altogether. If there is no iron, hy which I mean not even enough to hurt the zinc, the transformer product would not he dealt with in the wet way at all. The wet way is to get rid of iron and manganese, and to get out copper. Lead and silver can he got out by suhstitution in the fused state with great ease, hut copper has too high a melting point, and is therefore taken out hy the wet process.

To make a very safe estimate, the cost of all the process except the energy for electrolysis may he taken at a rough figure of 30s per ton of ore. This will easily cover all depreciation, a small percentage on capital, all lahor and management. As the process uses ores with ahout half the contents metallic, though it can work with half sulphides, this means ahout 30s per ton of chloride of zinc handled. Most of this work is pure circulation, agitation and filtration, all cheap processes. The solution is not hulky, as it is used as strong as the filter press cloths will stand. Evaporating down and preliminary electrolysis are the most expensive parts of the process, and they are not serious. The loss of chlorine, which has not yet heen determined, may he taken as costing about 1s a ton of ore for every 1% of chlorine wasted, if it is made up by huying chloride of zinc. If it is made up by hydrochloric acid or calcium chloride, which is far cheaper where there is no carriage difficulty, the cost is ahout half that of zinc chloride. This loss of chlorine is included in the 30s a ton of ore, and in the estimates to follow, as power is taken at prices in England where it is not cheap, we may assume we can get calcium chloride cheap. This does not complicate the estimate hy showing a zinc output a little higher than the intake in the ore.

The cost of energy is very easily determined. If it is generated hy steam engines of high grade in this country in a convenient district it may he taken as 0.25 per kilowatt-hour, including depreciation, coal, oil, repairs, lahor and management, and a small interest on capital. This is a close estimate, hut one which can he realized on large plants running day and night on uniform full loads. The cost hy producer gas and gas engines is somewhat uncertain; it may be taken at 0.125, though that is probahly a very tight figure. Water power in a favorahle situation may he taken at 0.085. This refers to water powers such as on the way down from the American lakes to the sea. It is for a works planted close to the generators, and does not cover rotary transformers or step-down plant.

As to capital cost, it is difficult to say how much the plant for any particular case will cost, as it depends on the ore to he smelted, and local conditions. It is therefore wise to allow a large margin on all the plant of a new description, and a large margin is left in the 30s a ton for depreciation, repairs, etc. The electrical generating plant is a different matter, however. A large installation may be taken at an outside figure of £25 per kilowatt, including buildings and spares. In this case there is no accidental overloading, as in light and power distrihution stations, so that £25 a kilowatt includes spares hy overloading and separate plant.

The idea of risk profits is this: Any new process such as this, however satisfactory the results so far, involves risks of failure. There are many chances of difficulties in working on a still larger scale, and chances of new and better processes coming out. The last chance is prohahly small, because the various problems of smelting copper, lead, zinc, antimony, tin, etc., have all heen before the world for many years, and a new process that hids fair to solve all of them in a new way is not likely to be superseded as regards many of them by something else, though it might be as regards one of them. The only risk is that of all new processes—unforeseen difficulties or expenses. The present process is too far advanced to leave many loopholes, but even then experience of other industries shows that it is not wise to emhark in a new scheme unless, after the most searching criticism, the profits on paper are so large as to leave a very wide margin. But to get a fair idea, it is ohvious that capital in steam generating plant, or in sites, must not all be counted in as expecting what are here called risk profits.

When treating ore having very little gangue, it might he worth while to dilute it with poor copper ore, especially if the copper ore contains some other metal, such as zinc, antimony, nickel or precious metal. Thus if the ore has only 10% of gangue, and a low-grade copper with 3% of copper, 5% of zinc, and 5% of iron, has some 80% of rock; for every ton of the rich ore more than a ton of this poor ore could he run through too. The works would then deal with 100,000 tons of this poor ore with very little extra capital cost or expense, as it is nearly all rock, which is eliminated near the beginning of the process. A little more than £1 10s a ton for the process should have been allowed for the rich ore, and a poor ore takes a great deal less.

Discussing the different metals in order:

Antimony.—This metal is easily extracted from

*Abstract from Trans. Faraday Society.

the sulphide either as brown sulphide or as oxide, preferably as oxide. It can also be got out as regulus by reduction. It does not matter whether the antimony is mixed up with other metals or alone.

Arsenic.—This is essentially the same as antimony. Like it, its sulphide is easily converted into chloride. It can be equally easily treated when it is an arsenide of other metals. The chief difficulty of antimony and arsenic arises from the poisonous nature of their volatile chlorides. We have done little with arsenic.

Bismuth.—This is a small question. Bismuth would be easy to deal with, as it falls out of solution as oxychloride.

Cobalt.—This comes out as oxide; if nickel is also present, the nickel and cobalt and iron, and perhaps manganese, have to be separated in the wet way. There is nothing special about the problem.

Copper.—This comes out of the transformer as cuprous chloride, which is soluble in the other chlorides. It is deposited as cement copper by zinc, not iron. The process will handle ordinary high-grade copper ores successfully, as any other metal, except iron or manganese, is extracted separately as metal too. The copper is, of course, free from sulphur, arsenic, iron, antimony, phosphorus, silver, etc. Copper can be equally cheaply extracted from arsenical or antimonial ores, in fact the ores may have arsenic, antimony, zinc, lead, iron, nickel, gold, silver, cobalt, or anything else, and they are all separately extracted without appreciable extra cost. Poor copper ores will either be concentrated, or run in with other richer stuff.

Gold.—When present in copper, lead or other such ores, the gold comes out with the silver. Gold in conjunction with antimony, arsenic, tellurium, and small quantities (per ton) of common metals, can be treated as a low-grade ore and run in with any rich mixed or other sulphide, such as lead, zinc, or even rich copper ore or matte. It is largely a question of carriage, and what ores are near each other and near the works.

Iron.—This metal occurs in zinc and copper ores, and comes out as oxide. This oxide is reckoned as £2 a ton, and is useful as a paint. The value depends on the tint, and this depends on the way it is worked up, a matter we have not studied. Good oxide fetches high prices, up to £15 or £20 per ton, but the sale is very limited. Assuming the lowest price, £2 is not too much to count upon for paint for preserving iron structures where color is not an object. The extraction of iron itself is a different question. It would come down as a powder from the fused chloride, and would have to be fused together. It would probably cost something under £10 a ton. It may prove that chemically pure iron, with no trace of phosphorus, sulphur, silicon, or manganese, or other impurity, is well worth £10 a ton for making special steels.

Manganese.—This metal, like iron, is a drawback in an ore, as it comes out as dioxide, which is not valuable, though the sale of the manganese from such an ore as Broken Hill slimes is worth considering.

Nickel.—This is much the same as cobalt as far as the process goes. It comes out of the transformer as nickel chloride.

Silver.—The silver comes out separately—that is to say, it is extracted from a lead ore as a rich lead-silver alloy. From copper ores it is precipitated by cement copper from the solution of the chloride. Or it may be thrown down by the Claudet method.

Tin.—Tin ores can be added to the charge of the transformer, or treated alone. There is nothing peculiar about it.

Zinc.—Has been fully discussed. Zinc need not exist in the ore worked.

As it is not possible to give a series of estimates for all the innumerable complex ores, it may be well to give an approximate rule which can be applied to any ore.

RULE FOR CAPITAL REQUIRED.—For each ton of ore per annum to be treated allow:

Zinc	£0.1 per unit.
Copper	0.05 " "
Lead	0.03 " "

And for other metals which are extracted in the metallic state, in proportion, inversely as their equivalents. Metals like iron and manganese or antimony, which are extracted as oxides, do not count. This gives a very rough idea of capital necessary for process plant and working capital. If steam or gas generating plant is to be put down, double this capital.

MINING offers more attractive and better opportunities for investment than any other industry, for mining is not yet controlled by a trust.

Electricity in Placer Mining.

Written by J. E JOHNSTON.

The development of the mineral resources of Colorado has been very materially aided in many instances by the utilization of the energy of her mountain streams, electricity being the main medium of application. The intermittent character of the flow of those streams, however, has been a serious drawback to the extended use of water power in this section of the Rocky mountains. Still, for some purposes, this is not so great an obstacle as might at first seem. This is especially so in the case of placer mining, which can only be prosecuted during the summer months, at which time even the most insignificant of these streams becomes a torrent.

The Goldpan M. Co. of Breckenridge, Colo., is said to have the largest placer mining plant in the State. This plant, outside of the direct application of water under pressure to the washing of the gravel, and elevating the same from the pit, is largely operated by electricity.

Spruce creek, 5 miles above the present scene of operations, is the source of power. This is diverted from its natural channel and conveyed to the pressure box by means of a ditch some 2 miles long. From the pressure box to the generating station the water is conveyed in a steel pipe of varying diameter and thickness to suit requirements. The total effective head is 425 feet, and the working pressure about 206 pounds.

The generating plant consists of two 200 K.W., alternating current, Westinghouse generators, delivering 2-phase current at 440 volts, and direct connected to two Pelton water wheels.

The arrangement of these generators and wheels is novel. The wheels are set as closely together as possible to allow their extended shafts to pass each other. The shafts are thus parallel, and of the same length and 4 feet apart. On one end of each shaft is mounted a half of a flexible coupling of the leather-link type. At each end of this arrangement is placed a generator which by a tension screw and guides can be placed so that its half coupling can engage with either shaft. Normally one generator will be used on each wheel, but the plan allows either wheel to be operated with either generator, and provides for emergencies that otherwise could not be met.

Sub-station of Goldpan Mining Co., Breckenridge, Colo.

Two exciters, each of capacity sufficient to excite both generators, are provided. They are direct connected each to a suitable Pelton wheel.

As a portion of the current generated is used in lighting the town of Breckenridge, and the remainder is applied to motor work of an intermittent nature, the switchboard is provided with two sets of bushars, which allows of either multiple or separate running. This board is of blue Vermont marble, provided with a full line of measuring instruments of the long scale type.

The raising transformers are located in a separate building. The line pressure is 10,000 volts, 3-phase, it being the intention to ultimately cover greater transmission distances than now used.

The line is of No. 5 copper, two circuits of three wires each, of one set of poles. Glass insulators are used.

The principal use in mining to which the power is applied is the driving of pumps, lighting the pit, etc. Two electrically driven portable cranes are used in moving larger boulders. These cranes are of the boom type, and are equipped with variable speed alternating current motors capable of exerting 30 H. P. One 150 H. P. constant speed motor is used to drive a centrifugal pump and assists in keeping the pit dry. There is also a well-equipped machine shop driven by a 50 H. P. constant speed motor. In this shop were made the large wrought steel water mains used in the placer system.

Distribution of current is made to these motors in 220 or 440 volts, according to location, from a sub-station at Breckenridge. The lighting of the town is from 2200-volt mains from the same sub-station.

Placer Mining in Southern Oregon.*

Written for the MINING AND SCIENTIFIC PRESS by DENNIS H. STOVALL, B.S.

Placer mining in southern Oregon several years ago passed the romantic stage, and has resolved itself to a conservative industry, and the many large hydraulic mines that are now robbing the old channels and auriferous hills in the southern Oregon placer fields of their gold are conducted on business methods. The numerous auriferous deposits in the many streams, the mild winters, and the absence of restricting mining laws, make southern Oregon an ideal mining region. Beds of ancient channels are found along the rivers and streams. It is in the gravel of these ancient channels that the hydraulic mines are located. The dirt, the gravel and the decomposed matter of these old channels are all auriferous in depth from 8 to 200 feet.

It requires capital, skill and much labor to properly equip a southern Oregon hydraulic mine. After the diggings have been successfully tested by thorough prospecting, the next important problem is the water supply. (See illustration, front page .) From the headwaters of the nearest stream the water is conveyed around steep mountain sides in ditches that require in places as much work to construct as would a railroad. Long flumes, trestled high, lead the water across deep canyons and gulches, and in many instances long tunnels are driven through mountains. After 10, 20 or 30 winding miles the water is brought to the reservoir on a hilltop several hundred feet above the diggings. The steel pipes lead down to the diggings from the reservoir and, forking, branch off in smaler pipes to the several giants.

As the amount of mining done is dependent upon the water supply—other things being equal—that miner who has the best supply for the longest season is the most fortunate. This fact, and the recognition of it, has brought about many important improvements in the matter of hydraulic mining equipment in southern Oregon in recent years. Placer miners are enlarging their ditches, building bigger and better reservoirs, and doing all possible to keep up a "pipe head" as late in the summer as possible. Formerly a large number—in fact, nearly all—of the placers were obliged to close down early in March or April. Now many of the larger ones operate their giants night and day till June and July, and a few during the day throughout the summer. One mining company, operating on Galice creek, is now at work building two storage reservoirs at the head of their ditch, that the giants may be supplied a steady and constant flow all summer.

As the amount of placer ground which a majority of the mines possess is very large, the question of getting the greatest returns for the labor and capital invested resolves itself to the matter of keeping the giants turned on the gravel banks continually. Closely allied with this is the saving of the gold after the gravel is disintegrated, and sluices are so constructed that with a system of undercurrents not only the coarse gold is caught, but also the flour gold, only a very small percentage of the dust-like particles escaping. Hungarian riffles, block riffles, crosshar riffles, pole riffles and the ordinary bedrock riffles are employed in the sluices to catch the gold. The natural rock riffle in the bedrock race proves to be one of the best for catching gold, and it is here that nearly all of the nuggets and much of the finer gold are found. The sluice boxes are arranged at the end of the bedrock race. Specially prepared crosshar riffles, made of steel, fit in the bottom of the sluices, and are the most used by the hydraulic miners of this section. Farther on, down toward the dump, the last opportunity of catching the gold is utilized by block and pole riffles. The undercurrents are placed alongside the sluice boxes and so arranged that the water, black sand and finer particles are drawn off and spread out over a broad riffle table, where the sand and fine gold particles settle.

For night work the larger mines have a score or more of arc lights suspended over the diggings. These are run by the mine's electric light plant. Others use locomotive headlights, stationed conveniently about the grounds.

After the first expense of buying and equipping the mine, it costs at the most favorably situated mines from 1½ to 5 cents a yard to hydraulic in southern Oregon. The gravel generally pays from 6 to 20 cents a yard. The average is between 8 and 12 cents. Giants pay from $75 to $100 a day each.

All placer ground in this section is what the miner calls "spotted"—the values are not regularly distributed. All, however, are possessed of the same characteristics. On the bottom, next the bedrock, are the boulders, the nuggets and coarse gold. Above this is the finer gravel and dirt, lying in strata of

*See illustrations on front page.

blue and gray. Still above this is the capping of red clay, which carries values in flour gold.

"Clean-up," as the miners term it, usually comes at the end of the season, when there is no longer sufficient water to supply the giants with a full pipe head. The bedrock race is first swept clean and every particle of the precious metal gathered up. The riffles are then lifted from the sluices, thoroughly rinsed and laid aside. With a small stream of water flowing through, the mass of gold and dirt on the sluice floor is swept gently to and fro with a brush broom. The dirt and refuse are carried away by water and flow off over the dump, revealing the black sand and the gold particles in the bottom. The gold is held as an amalgam by the quicksilver that is sprinkled frequently into the sluices during the process of mining. The coarser pieces are first gathered up and the remaining mass swept into piles, scooped up and put into strong bags or glass jars. This done, the gold is ready for the refinery and mint.

Notes on the Metallurgy of Copper of Montana.*

NUMBER III.

Written by H. O. HOFMAN.

The 36-foot furnace does better work than the first one built, which has the same width of hearth (viz., 6 feet) but is only 30 feet in diameter. If, nevertheless, the tonnage appears to be comparatively low, and the percentage of sulphur left in the roasted ore somewhat high, this must be attributed to the large amount of zinc present.

In the double-deck furnaces in which the ore, fed on the upper hearth, drops through a slot in the roof onto the lower hearth, the floor of the upper hearth and the roof of the lower hearth are separated by an air space 2 feet high. A furnace with a 6-foot hearth (area 1010 square feet) treats in twenty-four hours 30 tons of concentrates (59 pounds per square foot of hearth area) containing Cu 12%, Zn 8%, S 35%, Fe 25%, As 3%, SiO_2 16%, Ag 20 ounces per ton, with a reduction of the sulphur to 6% to 7%, 400 pounds of coal being burned per ton of ore.

A furnace with a 7-foot hearth (area 121,829 square feet) treats 42 tons (69 pounds per square foot hearth area) with a similar elimination of the sulphur and a fuel consumption of 182 pounds per ton of ore treated.

Comparing the pounds of ore roasted per square foot of hearth area in the two furnaces (59 and 69 pounds), an improvement of 15% in favor of the 7-foot hearth is seen. The degree of desulphurization is about the same in the two furnaces. The consumption of fuel, however, has been reduced from 400 to 182 pounds, or 55%. The labor required to fire a single-deck furnace is the same as with the double-deck, and that for supplying ore and fuel and removing roasted ore and ashes from one double-deck furnace is, of course, smaller than from two furnaces with single hearths. Thus the double-deck furnace is a decided improvement over the single hearth as long, be it understood, as ores are treated which do not frit or form accretions on the hearth.

The six-deck furnace resembles the double-deck furnace in the stirring mechanism, and with it the passage of ore and gases. It has one fireplace (3 feet by 3 feet 2 inches) on the top hearth, and one 4 feet 3 inches by 3 feet 2 inches on the bottom hearth.

It differs from the double-deck furnace in the number of hearths, six vs. two; in the fact that there are no air spaces between the superimposed hearths, the roof of one forming the floor of the next one above, and that the portions of the inner wall above the horizontal slots of hearths one to five have cantilever supports, with trussed cords projecting from the central column. This makes rather a complicated structure, requiring a large number of iron parts of various sizes, some of considerable weight. The iron parts of the furnace weigh 165 tons. The furnace is 32 feet in diameter and 20 feet 9 inches high. The hearths, 7 feet wide, are 2 feet 9½ inches from roof to roof, which is 4½ inches thick. The sand filling forming the working hearth is 5 inches thick at the crown of the roof and 12 inches at the sides. The distance from the working hearth to the inner slot (protected by 1-inch castings) is 6 inches, and to the springings of the arch 16 inches. The rise of the arch is 8 inches. A hearth has four stirring arms, making one revolution in sixty-five seconds. The horizontal flues in the outer walls are omitted, through which air passes in the older furnaces, in order to be warmed and admitted to the surface of the roasting ore. Around the furnaces are platforms to facilitate access to the hearths. The moist concentrates, dumped into the shoe of a bucket elevator, are raised to the top of the furnaces and discharged into a hopper, partly closed at the bottom, by a corrugated roller feed. This delivers into a slot, 8 inches wide by 7 feet long, in the roof of the top hearth. The furnace roasts 56 tons of ore in twenty hours, or 38 pounds per square foot of hearth area. It makes 4% of flue dust on the weight of the ore charged, and requires 28.5 pounds of slack coal per ton of ore. The quality of the work is similar to that of the double-deck furnace. The amount of ore roasted per square foot of hearth is a great deal smaller, but the saving of fuel is much larger. The low fuel consumption brings out in a striking way the benefits that are derived by diminishing the loss of heat by radiation.

The MacDougall furnace is a vertical cylindrical furnace with arched horizontal hearths having discharge openings alternately near the center and periphery, and a central revolving shaft with horizontal radial stirring arms, which are provided with teeth placed at an angle to the arm. The teeth of the arms on the even-numbered hearths are set in a direction opposite to that of the odd-numbered. Thus on the odd-numbered hearths they push the ore toward the center, and on the even-numbered toward the side. The ore, fed mechanically onto the furnace, is delivered continuously onto the outer edge of the first hearth, when the teeth of the stirring arm turn it over and work it toward the center, where it drops through an annular opening onto the second hearth. The arms of this, turning the ore over and over, will convey it slowly to the openings near the periphery, through which it drops onto the third hearth, and so on until it arrives on the closed bottom, where it falls through drop holes into a hopper.

The ore, spread evenly over the hearth, thus travels in zigzag through the furnace, passing from periphery to center, and vice versa. It is warmed at the top of the furnace; it then ignites and burns freely, and, lastly, most of the sulphates formed are decomposed lower down. The air necessary for oxidation is admitted through doors in the side, most of it entering on the bottom hearth. The gases, and with them the dust, pass upward through the ore-discharge openings and are drawn off through pipes in the roof. In starting, the furnace has to be heated up to the kindling temperature of the ore, which, if rich enough in sulphur, will burn of its own accord, without the use of any carbonaceous fuel. If too low in sulphur, the heat necessary for successful roasting has to be supplied by one or more external fireplaces.

Three kinds of MacDougall furnaces interest us here—the original MacDougall, the Herreshoff and the Evans-Klepetko.

The original MacDougall furnace was patented by MacDougall Bros. in the beginning of the seventies, and was in operation in Liverpool, England, burning pyrites to furnish sulphurous gases for the manufacture of sulphuric acid. It had to be abandoned on account of the large amount of flue dust formed and the many mechanical difficulties encountered. The furnace, 6 feet diameter and 12 feet high, was built of seven cast iron cylinders bolted together and had six closed chambers. A 2 H. P. engine was sufficient to drive the mechanism. The furnace roasted in twenty-four hours 3½ tons of pyrites, or 0.020 ton per square foot of hearth area, reducing the sulphur to 2%.

The Herreshoff furnaces in operation at Butte have a ¼-inch steel casing. They are 10 feet 10 inches in diameter and 11 feet 6 inches in height, and are lined with a full course of red brick. A few furnaces built of two full courses of brick and only hooped with iron bands are doing better work in cold weather than the furnaces sheeted and lined with a single course, thus showing that with ores running low in sulphur, when heat has to be husbanded, an 18-inch side wall has its advantages. A furnace has five arched brick hearths, 4½ inches thick and 12 and 13 inches apart. The pitch of the arch is 4½ inches. A current of air passes through the hollow central revolving shaft, which is 14 inches in diameter. The hollow horizontal cast iron stirring arms, two to a hearth, have seven and eight teeth, respectively. They are easily exchanged when worn out.

The top hearth acts as a drier; the second starts the roasting; on the third the ore roasts freely—innumerable sparks are seen; on the fourth there are no sparks, and on the fifth floor the ore looks dark. A furnace, with its shaft making fifty revolutions per hour, roasts in twenty-four hours 5 to 6 tons of wet concentrates with about 35% of sulphur, or 0.015 ton per square foot of hearth area, reducing the sulphur to 6%. Seventy furnaces make 4 to 5 tons, or 6.4%, of flue dust.

Shortly after the Herreshoff furnace had proved a success a larger furnace, 16 feet in diameter, was constructed on the same general lines. It had eight hearths, an air-cooled shaft and eight solid cast iron arms. The heat generated was sufficient to cause the arms to bend under their own weight. Air cooling having proved unsatisfactory, water cooling was substituted, and the number of hearths reduced from eight to six. The leading differences, then, between the Evans-Klepetko and the Herreshoff furnaces are the size and the water-cooling of the central shaft and the stirring arms. The furnace is 18 feet 3½ inches high and 15 feet 10 inches in diameter. It is sheathed with ⅜-inch boiler iron and lined with a full course of red brick. It has six arched hearths, with a 9-inch spring and 3 feet apart. Each hearth has two stirring arms making sixty circuits per hour. The furnace stands on columns 12 feet high, to allow the roasted ore to be collected in hoppers and discharged into cars. Six furnaces form a battery. They are placed, from center to center, 18 feet apart in one direction and 21 feet 3 inches in the other. Each furnace has two gas flues, 2 feet in diameter and 12 feet apart, passing out of the roof. The flues from three furnaces lead into one main 6 feet in diameter, having openings along the top and bottom for removing the flue dust. The bottom openings have vertical pipes, which are connected directly with the calcine hoppers. The central shaft of a furnace is driven from below. Three furnaces receive their motive power from one main shaft, with which they are connected by friction clutches. A clutch can be thrown in or out from each of the six platforms surrounding a furnace. The cooling water is forced down to near the bottom of the revolving hollow shaft (9 inches inner diameter) through a 3-inch pipe and out to the ends of the horizontal stirring arms through 1-inch horizontal pipes. In its upward passage between shaft and pipe it takes up the return water from the stirring arms and discharges at the top through two spouts into a stationary launder. Shaft and arms are made up of flanged sections to permit easy exchange. Running the overflow water at 80° C., twenty gallons of cooling water per minute are required by a furnace. Forty-eight furnaces are supplied with the necessary draft by a steel stack 200 feet high and 23 feet 6 inches inner diameter, the lower 20 feet being lined. A 30 H. P. motor is provided to run the machinery. Tests have since shown that 10 H. P. is required for six furnaces. When ore too low in sulphur to be self-burning—i. e., about 28%—is to be roasted, one auxiliary fireplace for two furnaces, placed on the level of the bottom floor and delivering the flame onto the fourth floor, furnishes the additional heat required.

(TO BE CONTINUED.)

Tiburon Island and the Seri.*

TO THE EDITOR:—It is about time that something was being said concerning the truth in regard to the Tiburon Island and the man-eating Seri. Our daily papers are continually publishing interesting fiction in regard to Tiburon Island, thereby causing numerous men to venture there in search of the precious metals and to explore an unknown land. To a number of American prospectors here in Sonora it is all a good joke when they read of a party coming down to explore the Tiburon.

The island has been prospected a number of times by both Americans and Mexicans since 1884. The writer was engaged last year, by parties having a mineral concession and an option on the island, to report on the mineral resources and the Seri Indians. This expedition left Guaymas on Nov. 19, 1902, in the gasoline launch Lollita, with a total of twenty-three men aboard. The next day we landed on the southeast end of Tiburon Island and immediately began our search for the minerals said to be there.

The party was divided and sub-divided many times, and seven days were spent in ceaseless prospecting all over the island, which is about 15 miles wide and 28 miles long. Needless to say, there was no mineral found nor any indications of any, as the island is composed mostly of lavas, volcanic conglomerates, tufas and eruptive rocks. At the southwest end the hills rise very precipitously and show plainly their formations and various strata. Inland, near the bottom of a deep canyon, granite was noted; a flow of basalt makes a direct contact with the granite, which apparently is the first of the lava flows on this end of the island. Above this are volcanic conglomerates and tufas. Near the central portion there are great flows of rhyolite, capped by andesite, which forms the higher portions of the mountains.

Obsidian was noted in some hills on the eastern side in large masses. The northeast end is composed of low, rolling hills, consisting mostly of coarse granite, some of which is iron-stained, giving a reddish color to the hills.

An irregular belt of micaceous rock, separating the granite from the volcanic formation, here was found—the only quartz on the island, but in small pieces no larger than a man's hand, coming from small stringers and seams in the mica schist, but very white and barren.

Some lime and a deposit of fine marble were seen.

The northwestern and western portions are made up entirely of eruptive rocks and lavas and are devoid of all mineral indications. The hills and mountains are pitted with small caves and pockets, caused by the erosion of the soft material which was encased in harder ones.

I should judge there to be an uplift of the entire island of 200 feet on the south end to 300 feet on the north end, as shown by ancient beaches, sea shells and fossils embedded in the conglomerate at that height above the present sea level.

Very little water was found—in fact, there is not sufficient to supply the needs of the Indians who make the island their home.

A stunted growth of brush and cacti covers the valleys and slopes from the water's edge to the hills.

THE SERI INDIANS.—Our experience with the Seri Indians was of a very friendly nature, although the introduction was slow and backward, owing to the precautions taken by both parties. As the fear gradually wore away, much trading and talking were indulged in. The chief, who has the name of Juan Tomas, is quite an intelligent man of about 50 years, speaks Spanish and is a good diplomat. There were

* See illustration on front page.

twenty-six men and boys in their party, and I have no doubt that number constituted all the able-bodied male Seri on the island. They were all in good health and form, but only partially clothed. Some have very fine physique—in fact, the best I have ever seen. Their features and hair are decidedly of the Indian type; but all are very filthy and dirty in their habits.

The principal food is fish and turtles, which abound in the waters that surround the island.

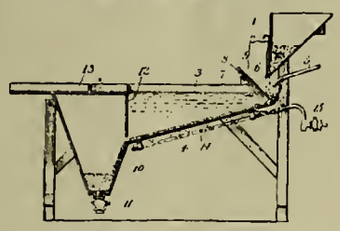
For weapons they have bows and fierce-looking arrows. I saw three old-style Remington rifles among them.

Most of them speak the Spanish language, having learned it when trading and working on the mainland.

Very little attention is paid to the building of their houses; a few small sticks stuck in the ground with the tops bent in, some brush around the sides, is "home sweet home" to the Seri.

I most certainly believe that when these Indians are not aggravated, or forced to defend themselves, they will not harm any one.

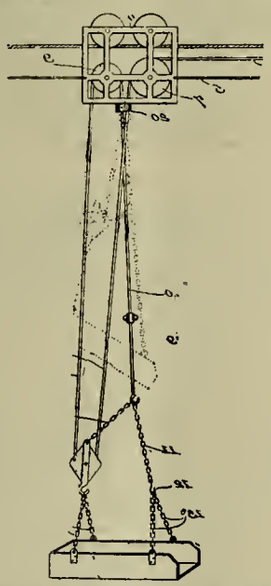
They have no ambition—desiring nothing but the necessities of life, peace, and to be left alone by daring explorers and fierce conquerors—and the Tiburon Island is the one and only place for them.



H. GORDON GLORE.

Mining and Metallurgical Patents.

PATENTS ISSUED AUGUST 8, 1903.

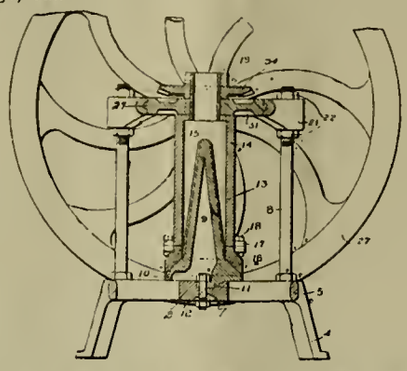


Specially Reported and Illustrated for the MINING AND SCIENTIFIC PRESS.

EXTRACTION OF ZINC, LEAD AND SILVER SULPHIDES FROM THEIR ORES.—No. 735,071; G. D. Delprat, Broken Hill, New South Wales, Australia.

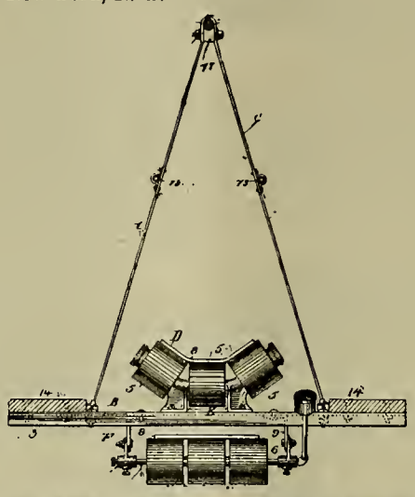
Method of separating ore from gangue by forming bath containing nitric acid, feeding finely ground ore thereto, whereby gas bubbles formed on ore particles to raise them to surface of solution, and removing particles of ore so lifted to surface.

DUMPING APPARATUS.—No. 735,139; A. E. Norris, Cambridge, Mass.



In apparatus support, fall rope depending therefrom, fall block supported in bight of fall rope, fall block and end of fall rope having means to which load supporting device may be detachably secured, and means to arrest movement of end of fall rope as load lifted whereby load is discharged.

PROCESS OF OBTAINING LEAD OR OTHER METALS FROM ORES OR MATTES.—No. 735,098; C. Hoepfner, Frankfort-on-the-Main, Germany.



Leaching compounds containing lead, silver, iron and zinc, with solution of cupric chloride concentrated in sodium chloride, removing silver by copper in contact with mercury, precipitating iron by oxychloride copper, removing lead as sulphite by monosulphite of zinc, precipitating copper from resulting zinc-chloride solution by zinc, decomposing resulting zinc-chloride solution to recover zinc, and returning resulting solution and free chlorine from decomposition of zinc to leach fresh quantities of ore.

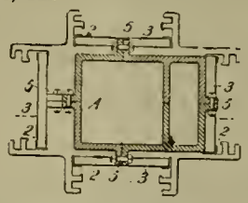
QUARTZ MILL.—No. 735,234; J. F. Forward, San Diego, Cal.

Combination with base having non-circular recess, of grinding member composed of hollow cone having frustum-shaped lower end and non-circular lug extending inwardly from lower edge thereof, lug engaging non-circular recess in base and connecting detachably therewith by means of fastening member extending through aligning perforations in lug and base.

CONVEYOR APPARATUS.—No. 735,301; T. Robins, Jr., New York, N. Y.

A suspension bridge for conveyors consisting of cable, platform, diverging hangers between cable and platform and belt supports above and below platform.

MINING TOOL.—No. 735,356; T. M. Fisher, Montgomery, Ind.

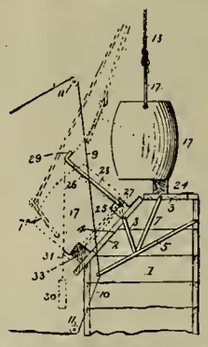


Combination, in tool, of handle, disk centrally pivoted to handle, means for limiting inward movement of disk to position such that plane of disk inclined to handle, means limiting outward movement of disk to position perpendicular to handle, means for locking disk in such position.

TREATMENT OF ORES CONTAINING GOLD, SILVER, COPPER, NICKEL AND ZINC.—No. 735,512; H. Hirsching, San Francisco, Cal.

Process of treating roasted ore and tailings by washing with water, leaching with ammonia, or ammonium sulphate, chloride or nitrate, adding water or boiled-out solution obtained by operation of process, and recovering therefrom metal or metals separately and ammonia.

STAMP MILL MORTAR.—No. 735,374; J. H. Hendy, San Francisco, Cal.



In stamp battery, series independent mortars each adapted for single stamp and divided vertically to form separable sections, sections having abutting flanges, means detachably securing sections each mortar, sections having screen discharge openings, sole plate common to series mortars, receiving trough rigid with sides of mortar below screen openings, inner sides of outer mortars of series and both sides of intermediate mortars being devoid of troughs, supplemental troughs receiving output of inner sides of outer mortars and both sides of intermediate mortars.

BUMPING SCREEN.—No. 735,525; H. L. King, Denver, Colo.

In bumping screen, combination with main frame, including crossbar 2, operating shaft, cam C mounted thereon, and bumpers 20 20, of screen frame, members 10 10 secured to front end of screen frame and projected below screen frame, brackets pendently secured on main frame to which lower end of members 10 10 are secured, central guide and support for rear end of screen frame, upon which frame has sliding movement, and springbars 11 11 secured at upper end to rear end of screen frame, lower ends being free to extend in close proximity to crossbar 2.

AUTOMATIC DUMPING DEVICE FOR ORE BUCKETS.—No. 735,571; R. Nye, Moline, Ill.

In device for dumping buckets, combination of incline, yoke-shaped inclined carrier pivoted to upper end of incline and bearing feet for engaging rim of bucket, counterpoise weight connected to carrier to retard tilting movement of bucket, and heel block located to engage one side of bucket to tilt it into embrace of carrier.

PROCESS OF EXTRACTING GOLD AND SILVER FROM ORES.—No. 735,501; C. A. Harp and J. F. Starkweather, Sr., Stockton, Cal.

Process treating ores, containing precious metal, consists pulverizing ores, adding thereto kaolin, brick dust, unburned limestone, sawdust and charcoal, agitating mass and subjecting same to proper degree heat, and when added ingredients have performed their functions adding saltpeter.

Mining Summary.

Specially compiled and reported for the MINING AND SCIENTIFIC PRESS.

ARKANSAS.

BOONE COUNTY.

The Bear Hill Co., at the head of George creek, near Harrison, where a sawmill was operated several years ago, is preparing to put in heavier machinery.

NEWTON COUNTY.

Manager E. F. Bickert of the Ponca City M. Co. is putting in additional mill machinery at his mine in west Newton county, near Harrison, Boone county. He he has elght men doing development work.——The prospecting drill for the Manhattan M. Co. is on the ground at the the company's mine, 4 miles southwest of Marble City, says Manager Anderson of Harrison.

ALASKA.

At the Alaska-Juneau M. Co. mines in Silver Bow basin, near Juneau, development work will be increased and the company's surveyors are running lines to ascertain the most advantageous route for a tunnel at tide water. Two more tunnels are being driven to open the lower levels. It is intended to build a mill, but Gold creek, it is claimed, will not furnish over five months power for a large stamp mill. However, a tunnel will go in from tidewater and a stamp mill go into the hasin, pending the completion of the tunnel and the construction of larger mills on the heach, says the Alaska Dispatch.

Prospecting and development work is showing on Kodiak island some free gold properties, says Sargent, collector of customs at Kodiak, who is working a group 4 miles from there. Wander & McIntyre have a showing of copper ore on Uganuk island, near Kodiak. On Yuak hay, 40 miles distant, a 5-stamp mill is operating. On Red river four men took out $4000 in three months from placers this season.

R. B. Day of the Mansfield G. M. Co. on McGinnis creek, near Juneau, says they have their 1000-foot flume in operation and the ground is showing up well. They have heretofore heen taking water from Quartz creek. Day is arranging to put up additional huildings and will get out lumber for the 700-foot tunnel that he will put in next season so that they can use all the water from McGinnis creek.

M. J. Sullivan reports finding gold-hearing quartz on Trilby mountain, in Nome district. Trilby mountain is near junction of Solomon river and Hurrah creek. A shaft has heen sunk on the foot wall 28 feet ln free milling ore.

There are tin ledges along Behring sea at Cape York, north of Cape Nome, says Manager W. C. J. Bartels of a company organized in New York to exploit the tin resources of that region. A crushing plant is heing set up at a new town called Tin City, 15 miles ahove Cape York and 10 miles from Cape Prince of Wales. An experimental plant, to he operated by gasoline and electricity, is going in. It includes three electric drills to he used in prospecting and a tin stamp mlll will follow.

ARIZONA.

GILA COUNTY.

The July production of the Old Dominion mine at Globe amounted to 700,000 pounds of copper, or 100,000 pounds more than for June, the running of two furnaces securing this increase, says President Smith.

A third interest in the Oxbow group, north of Payson, has heen sold to J. B. Newman. It is in the Green Valley mining district and consists of ten claims. There is a 10-stamp mill in operation.

GRAHAM COUNTY.

The tramway for the Standard copper mines, near Morencl, is on the ground and is being set up. When the tramway is in operation the output of the company will he increased, and the cost of transportation is expected to be reduced by $2 per ton.

MARICOPA COUNTY.

J. K. Truman, superintendent of the Climax G. M. Co., operating at Quartz mountain, near Phœnix, says he has been putting ln machinery on the Orizaha group, being operated hy the Orizaba M. Co., of which he is manager. The property is 45 miles north of Phœnix. The machinery consists of a 25 H. P. boiler and a 15 H. P. hoist, which will give them a capacity for sinking 500 feet. The ore is iron and copper sulphides, carrying 10% copper and $3 in gold. The shaft was started in the canyon, which is 300 feet from the top of the mountain.

MOHAVE COUNTY.

(Special Correspondence).—The Tennessee mine, near Chloride, has ceased all work, except one engineer to keep water out of lower workings, the reason for which has not been given.——J. Kenney and L. Lapping report a strike of gold ore on their Larna mine, near the Century and Altata mines. The vein is 20 inches wide near the surface.

Shaft No. 2 on the Century mine is reported also in good ore ln the work down 80 feet. At 100 feet drifting on the north end of the vein is to he started.——The Samoa mine is in another hody of ore in the 400-foot drift of the 350-foot shaft. This is the catching up of the 1000-ounce silver ore that gave out last spring.——J. H. Boaks of Los Angeles, Cal., is negotiating for a bond and lease on a group of eight claims, of which the Century, Larna and Altata mines are the principal.

The St. Charles Bros. & Babcock continue driving the east drift on the 250-foot level of the Midnight mine. A large hody of low-grade ore is showing.

The Pastime mine, at Mineral Park, is being opened up again after an idleness of four years. The ores carry values in silver. Sinking will continue.——The Tintic mine, which was recently taken over hy Hawks & Shaefer, has the whim in operation and the lower workings are heing unwatered. This finished, further sinkiug will he done in the 90-foot sbaft and drifting started both ways on the vein.

Chloride, Aug. 9.

Ten men are at work on the Paymaster mine, north of Cerbat, and ore is being shlpped to the smelter. The ore carries values in gold and silver.——J. Barry has men at work on the Gold Nugget mine, near Cerbat, and is getting out ore.

It is reported the Minnesota-Connor mines, near Chloride, will he started up about Sept. I, and the main shaft will be sunk to depth of 1000 feet.

PIMA COUNTY.

F. Brownell, superintendent of the Producer Copper Co., whose mines are 54 miles south of Casa Grande, in Quijotoa section, says the crosscut in the Century mine is in 30 feet from the 200-foot level and near the lead. The country rock shows sulphides. Some trouble was experienced with water. The fifty-ton smelter is in place.

PINAL COUNTY.

C. McCully and J. W. Benzie of Denver have bought the Christmas Gift mines for the Plata Cobre M. Co. of Denver, Colo. The mines will be equipped and operated on a large scale. They are 60 miles northwest of Tucson, Pima county. When first discovered $200,000 was taken out of one pocket.

YAVAPAI COUNTY.

The Yavapai Oil & Development Co. has been incorporated at Jerome hy J. C. & H. L. Heslet, A. D. Coover, J. Page and J. S. Waughtel. This company proposes to put an outfit on the ground near Del Rio and start drilling for oil.

Work on the Iron King smelter, south of Jerome, is nearing completion. The ore roast pile will he ready for firing next week. Fifty men are at work.

CALIFORNIA.

BUTTE COUNTY.

A. D. Bonham of Chico reports finding gold-bearing quartz 30 miles from Chico which has yielded good returns. He has made two shipments to the smelter.

CALAVERAS COUNTY.

The Independence gravel mine, east of Angels, has again started up and sinking the shaft is under way. Superintendent McIntosh says he intends putting the shaft down ln the rimrock to depth equal with that of the bedrock of the channel, and drift into the channel.

C. H. Blake, superintendent of the Fanny Marie mine at Glencoe, says it is intention of the company to resume on both the Fanny Marie and the Bluejay mines.

EL DORADO COUNTY.

The El Dorado C. M. Co. continues arrangements toward beginning heavy development work on the Eureka and Woodside mines near Georgetown.

FRESNO COUNTY.

There is a total of twenty-one companies operating in the West Side section of the Coalinga field, with twenty-nine completed wells and a number of others drilling.

INYO COUNTY.

At Millspaugh, at the head of Shepherd's canyon in the Argus Range, half way hetween Ballarat and Darwin, the Millspaugh M. & M. Co. is arranging to rebuild its mill and also to put up a cyanide plant.——Doningue, Etcharren and J. Carricart, who own the Red Star and Bryan mines near Millspaugh, report taking out free gold ore.——Tin ores are reported in certain ores of the camp.

KERN COUNTY.

The East Puente Oil Co., in Kern River district, near Bakersfield, has completed its sixth well and will drill a seventh.——The Southwestern Refining Co.'s plant is expected to be ready for operation hy October 1. The stills are heing set up.——The Con. Copper Oil Co., which has leased a portion of the Monarch's ground, is drilling its second well and has one finished.——The Alma Oil Co., W. E. Stevenson manager, will drill six additional wells. It now has two in operation.

The Veteran Oil Co. has heen organized with C. T. Deane as manager and will drill a number of wells on its holdings of twenty acres in the Kern river field, near Bakersfield.

The Peerless Oil Co. is pumping 5000 barrels a day. This will be increased, as the deepening of two of the wells first drilled hy the company will be completed and a new well, No. 25, will be finished next week. The drilling of new wells will be continued.

The Monarch of California Oil Co., at Sunset, struck oil last week in its third well at depth of 500 feet. The work is heing continued.——The Con. Copper Oil Co., which has leased a part of the Monarch ground, is drilling its second well and has one finished, says the Californian.

The Nevada County Oil Co, near Bakersfield, is drilling wells numbers 13 and 14, the first twelve wells being completed.

Wickard & Saunders are leasing on the Baltic mine, near Randsburg, and have bonded an adjoining claim for $2500.

Development work is reported progressing at the coal mine near Garlock.

Superintendent Bouchard at White's Camp, near Randshurg, says the main shaft is down 100 feet and two drifts are being run on the 100-feet level. They are drifting on good ore. At 175 feet from the main shaft a shaft is being sunk to connect with the stope on the 70-foot level, which will give circulation of air.

The Petroleum Center Co., near Bakersfield, will put in a pipe line from its property to the railroad. This company is resuming operations after being shut down for several months, and it is putting in a pumping plant ——The Eastern Con. Oil Co. has put in its hoiler at the refinery near the railroad, and the plant is expected to he in operation next week. A pipe line will he put in from the company's wells to the plant.

MONO COUNTY.

W. & C. E. Loose, of Provo, Utah, are reported to have hought the interests of their associates in the Sunshine, Coarse Gold, Hillside, Arthur and University groups of gold-bearing mines at Bodie, for $75,000. The equipment of the mines will be increased and further development done.

NEVADA COUNTY.

At the Huron mine, near Nevada City, the mill is in operation.

The work of pumping out the Le Compton mine in Willow Valley, near Nevada City, is finlshed and the mill will be started up this week.

The ten new stamps put in at the Union Blue Gravel mine, above North Bloomfield, hegan crushing gravel this week, says Superintendent Gassaway. This gives the Union Blue a 20-stamp mill of double-discharge capacity, and it is expected to require seventy-five miners underground to keep them dropping.

G. Lezlnsky of San Francisco, manager of the Gold Tunnel mine, near Nevada City, says the canvas plant was put ln operation last week.

The Mountain Maid mine, near Nevada City, will resume operations this month, says C. Pusheck of Chicago, Ill., manager.

This week operations will he resumed in gravel mining on the Middle Yuha, near Nevada City, by Root & Heisner. They expect to have 100 men at work shoveling gravel into the sluice. The sluice is 500 feet long, 20 feet wide at beginning and 18 at the lower end, with a continuous depth of 5 feet. A wing dam has also heen built to furnish water. They expect to have a continuous run of at least sixty days before the heavy rains set in, which will stop work for the winter, unless the ground can be worked out by that time, says the Union.

G. Snyder of Salt Lake City, Utah, part owner of the Red Cross mine near Omega, and S. E. Robbins, superintendent, are arranging to increase development. Prospecting operations have been carried on by tunnel, and a mill has been run by steam power. They will run a drain tunnel at depth of 1400 feet, and the mill is to be removed to a lower site, which will permit of water power being substituted for steam.

The Sierra Queen mine, near Nevada City, was closed down last week for an indefinite period. The mine has been operated hy its present owners for a year and a half. It is intended on reopening to put in a Cornish pump and sink deeper. The south side of the shaft has not heen prospected for fear that, on getting under Deer creek, the pumps could not handle the water. There is a 10-stamp mill.

A strike of gold ore has heen made in the Central Con. mine, on Little Greenhorn, near Grass Valley, says Superintendent Coffin.

The Pilgrim mine at American Hill, near Nevada City, was closed down last week by orders from Superintendent T. A. Patterson, who is in New York City.

PLUMAS COUNTY.

The Claybank mine, at La Porte, is able to run hut three or four shifts a week, owing to scarcity of water to drive the compressor, says the Bulletin.

SAN BENITO COUNTY.

(Special Correspondence).—At the Bradford quicksilver mine, 18 miles south of Tres Pinos, development work is being continued. The lowest workings are down 175 feet vertical, and the vein dips at 58°. A winze is heing sunk from the drift, near the shoot, which shows workable values in cinnabar. C. P. Bradford is manager. It is claimed they are on the same vein system which is being worked at New Idria, further south.

Tres Pinos, August 12.

SANTA BARBARA COUNTY.

At Summerland, J. F. Miller, who recently bought the property of the Mineral Oil Co., has renewed the lease of the M. F. Bishop ground and has five wells pumping. West of the Treadwell wharf four more wells, jointly owned hy Miller and J. L. Bryson, are heing placed in working order.

SHASTA COUNTY.

Preparations are being made to double the capacity of the DaLamar smelter at Winthrop. At present the smelter has one furnace of a daily capacity of 150 tons of ore. The new furnace will he huilt west of Furnace No. 1 and under the same roof. The Bully Hill Co. has already prepared for treatment of greater quantities of ore, as since the beginning of the year it has huilt more stall roasters and is beginning ta roast in the open air. It is also enlarging Tunnel No. 3, so as to allow for a double-track tramway. The tunnel is 1100 feet in length. The Anchor shaft is producing large quantities of black copper ore.

The Liberty group of mines near Copley, formerly under bond to the Great Western G. Co., has heen bonded to J. B. Wattermann, W. H. Dry and T. F. Gates of Philadelphia, Pa., for $150,000. There are 3000 feet of tunnels.

At French Gulch seventy-five miners at the Gladstone mine are reported out on a strike, due to poor boarding-house fare and the refusal of the company to decrease the working hours.

SIERRA COUNTY.

The Los Angeles Co., reopening the Kenton mine, near Allegheny, has twenty men at work under Superintendent A. Fitzgerald. Ore is being taken out and the 12-stamp mill is running steadily.

The Lecompton mine, in Willow Valley, near Nevada City, is again in operation, the work of unwatering having been finished last week. During the unwatering the mill was enlarged and the hoist also. New ground has been cleared for development.

SISKIYOU COUNTY.

P. Clark, of Spokane, Wash., has suspended operations on the Blue Ledge copper mine, near the Oregon line, on which he has a hond for $250,000, the reason given being that development is not satisfactory for the price asked. Clark had men at work driving a lower tunnel, and had also heen doing some extensive diamond drilling.

The Milwaukee M. Co., John Barth, manager, who bought the McKinley, New Discovery and Mountain Lily quartz mines on Humhug creek, near Yreka, last week, has also bonded the Golden Juhilee and other ledges in same section, says the News. Work is going ahead in the McKinley mine, with twelve men under Superintendent L. B. Jamieson, and a tunnel 300 feet in length has been run to the 12-inch ledge at lower depth. Later on the company intends putting up a mill.——P. S. Gallagher sold two of his claims on Cherry creek last week to C. Paige, and intends sinking a shaft on his McCormick mine in same district.

STANISLAUS COUNTY.

The supervisors of Stanislaus county have apportioned $12,000 as a honus to a combination of mining companies of the Coast Range mountains to build a road from the mines to Westley, and to put up reduction works and firehrick and tiling factories at Westley. The combination is composed of the Martel M. Co., owner of the Red Mountain district magnesite quarries; the James Manganese M. Co., and the Phœnix Quicksilver M. Co., owned hy E. P. Newhall and A. Hayward of San Francisco. The companies are said to have agreed to build the road and erect the works and factories at cost of $100,000.

TRINITY COUNTY.

The Senger and Hughes placer mines, near Weaverville, have been bonded to E. F. Burrill of Berkeley for $30,000. The Senger and Hughes properties comprise 420 acres of auriferous gravel and are between West Weaver creek and McKenzie gulch. Burrill has overcome the water question by leasing the West Weaver ditch and water rights from the La Grange Hydraulic Co.

E. G. Gould of the Rush Creek M. Co. of Oakland reports development work progressing at their mine, 1½ mile above junction of Minersville and Weaverville road. The ore is showing 4 feet in width, and averaging $20 a ton in gold. Two tunnels are being run in on the ledge.

The Hupp placer mine, at Weaverville, has closed down for the season, and the final cleanup showed satisfactory returns for the year's run. W. I. and J. Hupp, owners.

At Deadwood, the Brown Bear mill is crushing ore from the Lambert mine and also custom rock for the Lappin.——I. W. Zent, M. Carter and J. Thorne are putting in a ditch to take water from the Brown Bear tunnel. A good stream comes from the tunnel and will be flumed to the Three Brothers group to furnish power to the additional arrastra that is to be built.

At Hay Fork, the Hallstone prospect is being developed. The vein averages 18 inches wide of high-grade ore.

Superintendent T. Chambers of the Lappin mine, under bond to the J. J. Chambers Co. of Redding, reports a gold-bearing ore body found in the "Winze level," the lowest level in the Lappin. It is a 2-foot ledge. A milling and drilling plant will be put up, to be operated by electricity.

Superintendent J. S. Olds of the Chonchilulu Gold Reef M. Co., operating the Miner's Dream mine, on Chonchilulu mountain, at Bullychoop, says preparations are being made to put up a stamp mill, which is expected to be in operation by Oct. 1.

TUOLUMNE COUNTY.

The Dutch mine, at Quartz, is down 1400 feet, and drifting on the south level is in 80 feet. It is expected to cut the shoot that has been worked in the upper levels. A raise has been driven from the 1250-foot level to the 600-foot level, and a winze will be sunk to connect the 1250 with the 1400. The vein is 12 feet in width. The 20-stamp mill is running on full time and oil is used as fuel.

J. W. Stephens has bought the Union quartz mine, which adjoins the Rough & Ready mine, near Sonora, says the Independent.

The Vivian mine is being operated by W. S. Wilhelm of Sonora under bond, says the Independent, and a tunnel is in 160 feet to tap the vein.——The Georgiana mine (formerly the Garfield), on the East Belt, near Carters, has been bonded to C. Holland et al. of Sonora.——At the Mount Jefferson mine, at Groveland, the main shaft is down 520 feet, and they are sinking to get another level, says Superintendent J. Meighan. Fifty men are employed in mine and mill. Twenty stamps are dropping.

The Mayflower tunnel, 1 mile north of the Kanaka mine, near Groveland, is in 400 feet in limestone, and a raise is being put up, expecting to cut the gravel channel once worked at Corcoran Flat.

Development work is going on at the Longfellow mine, at Big Oak Flat, with seven men, and drifting is in progress on the 500-foot level.

The cyanide plant at the Rawhide mine, near Jamestown, is being doubled in capacity from 50 to 100 tons per day.

The Morris tunnel, near Columbia, has been completed to a point 15 feet inside the Bald Mt. and the Grant, Wainwright and Thomasson claims, says the Banner, and work is going on in a raise in the vein. They are up 40 feet and expect to cut the Austrian shoot.

A new air compressor and a 85 H. P. boiler have been added to the equipment at the Mohican mine, near Groveland.

YUBA COUNTY.

The New Blue Point mine, southeast of Smartsville, has been sold to East St. Louis, Mo., men, represented by J. Weisben. A permit to work the mine by hydraulic process has been obtained from the California Debris Commission.

COLORADO.

(Special Correspondence.)—During the past few months mining in Colorado has been rather slow. The conditions existing throughout the State have been detrimental. The labor question seems to have been the main cause. The operator did not know when his men would be called out in sympathy, therefore the new plant of machinery he was figuring on purchasing he did not buy, and no improvements were made. Conditions have changed somewhat for the better and the mining industry is improving. The machinary houses in Denver report a decided change for the better during the past few weeks. The labor difficulties are by no means settled, but it is the opinion of a good many that strikes have been checked. The union was unsuccessful in getting the men to go out at the Pueblo, Durango and Leadville plants, but in the Cripple Creek district they have called out about 3000 men in sympathy with the Colorado City smeltermen.

Denver, Aug. 10.

BOULDER COUNTY.

W. G. Shapcott, of Colorado Springs, treasuror of the Upper Ten M. & Oil Co, says increased development work is planned on a number of the thirty-two claims which they own near Eldora. Nearly 2000 feet of development work has been done on the thirty-two claims.

R. G. Mullen of Colorado Springs, of the Montgomery M. & R. Co., operating near Boulder, says the management has decided to double the capacity of the mill, which is twenty-five tons per day at present. The additions will include five cyanide tanks, three of which will have capacity of 100 tons each. Development work is progressing at depth of 240 feet. Two tunnels are being driven.

At Wallstreet the crusher for the Wallstreet mill was set up last week and operations started.

H. J. Newman and C. P. Campbell of Colorado Springs have bought the Lottie claim on Lee hill, near Sunshine, for $40,000, says the Telegraph. They will open and develop the mine and have cleaned out the shaft for retimbering. The pay streak is 15 inches wide.

CLEAR CREEK COUNTY.

The contractors in the Central tunnel of the Big Five Co., near Idaho Springs, report driving 115 feet in the first twenty days, working but one shift per day. The contract calls for 5000 feet of driving; $10 a foot is to be paid and the power is furnished by the Big Five from its power house near the mouth of the tunnel. The first 1797 feet of the tunnel was driven by the company prior to the erection of its power house. It costs $24 a foet, the size of the tunnel being then 8½x9 feet and double track. This contract calls for 5x8 and single track.

E. A. Eaton and F. G. Shaffer of Idaho Springs have located six claims on Santa Fe mountain along the mica vein that shows on the surface, says the Times, and will determine its commercial value. They claim about half of the product will produce sheets 2x4 inches and 40% of the product would have to be ground up if used, while 10% would produce sheets 8x12 inches in size. The owners are negotiating with the Crosson Bros. to merge the Starlight tunnel with the mica proposition. By driving this tunnel an additional 150 feet they would open the dyke at a depth of 800 feet.

The machinery at the Baltimore mine, near Georgetown, was put in operation last week and work in the tunnel started. Part of the tunnel will be enlarged to double track size and then continued to cut the Shively and other lodes which have been secured by the Hazleton Co.

FREMONT COUNTY.

C. M. McNeill, vice-president of the United States R. & R. Co., says the plants owned and operated by the company at Colorado City and at Florence, including the Standard mill at the former place and the Union plant at the latter, will be closed down within ten days (or as soon as supply of ore on hand is exhausted) on account of the strike in Cripple Creek district, inaugurated expressly to cut off the supply of ore from the company's mills. This will throw 500 men out of employment, all of whom are to receive one-third of their present wages for six months, in accordance with a promise made with the so-called mill trust last winter to those who stayed by the company at the time of the first trouble with the Western Federation of Miners. The two plants at Canyon City will continue work, McNeill claiming that there is enough ore on hand to keep the latter running for at least nine months.

During the last month in the Florence oil field four wells have gone into oil. The determined area and the oil production are increasing and new wells are continually being opened.

GILPIN COUNTY.

The Ideal G. M. Co. has resumed operations on its shaft on Tip Top mountain, near Perigo, and is down 110 feet and crosscutting to the vein. In sinking they went through the vein at 40 feet. The company intends putting in machinery. G. Waite is superintendent.

The Onoko Gold Mines Co., operating in Leavenworth gulch, near Central City, has cleaned out the shaft on the Paola mine to a depth of 228 feet. Drifting and stoping is being done in the 120 west level, where Superintendent Shull reports they have 12 to 18 inches of copper ore. A carload will be sent to the smelters. The company will erect a shaft building and install a plant of machinery.

G. R. Markey of Denver and J. Farland of Pittsburg, Pa., are reported negotiating to operate a group in Phœnix district, near Rollinsville, consisting of the Spar, Edwards and Attract lodes. Sinking and other developments will be started next week.

A. M. Hurd of Denver has a three-years' lease and bond on the Mountain Chief mine, thought to be the western extension of the Perigo vein, in the Tip Top section, near Perigo. Superintendent E. Stephenson of Phœnix will take out the water and sink the shaft another hundred feet.

The mill at the junction of Elk and Pine creeks, near Central City, is in operation, says Superintendent L. J. Mountz of Apex. It is of fifteen tons daily capacity and built to treat the ores of the Mackey and Sarah Jane mines, owned by Palmer & Mountz. They have decided to add two more mills, each of a capacity of fifteen tons.

The Nevada Con. M. Co. has a lease on the Pozo mine in Nevadaville, near Central City. This mine has not been worked the last few months, owing to the ore containing zinc. The new company has built a plant to treat zinc ores, says Superintendent Rucker. T. Marx is manager.

GUNNISON COUNTY.

Arrangements have been made to operate the Eureka mine at Crested Butte and zinc, lead, copper and silver ore will be produced.

S. Day of Gunnison is putting a whim on his mine at Elko and will take out ore for the Scofield mill.

HINSDALE COUNTY.

The holster at the Isolde mine, near Lake City, is in operation and unwatering the shaft on No. 1 vein. Shipments will begin this week.——The final transfer of the Pelican group on Henson creek, near Lake City, was made last week. The new owners will develop the ore bodies at greater depth.——It is reported the Dolly Varden mine in Engineer district, near Lake City, will have men at work next week.

Manager O. W. Pierce of the Tobasco mine, near Lake City, says operations at the mill and mine were resumed last week.——The hoist and pump for the Isolde mine is in position and work resumed in the winze to determine the size and value of the ore body.

The Hanna M. Co. will put in additional machinery and enlarge the capacity and change the concentrating system at its mill near Lake City. A. G. Ellis is superintendent.

HUERFANO COUNTY.

W. G. Shapcott, of Colorado Springs, of the Upper Ten M. & Oil Co., says they will develop their oil lands between Huerfano butte and the Pictou coal lands, northwest of Walsenburg.

LAKE COUNTY.

The buildings on the Sequin shaft at Leadville are up and the machinery is being set up.

There are four shafts of the Morning Star Con. M. Co, near Leadville, in operation at the present time; and while no new work is being carried on, the lessees are working through the Upper and Lower Waterloo, the McHarg, the Ladder and Porter No. 3 shafts, and are taking out seventy-five tons per day. A part of the tonnage is manganese coming from the Porter territory, while the McHarg shaft is opening up a manganese body. From the Evening Star ground twenty tons per day are being shipped from the old workings, says the Carbonate Chronicle.

LA PLATA COUNTY.

The holdings of the Devau M. Co. have been sold to the Expansion M. & L. Co. of Pueblo for $25,000. The Bay City group is 16 miles from Durango and 2 miles from the railroad. Coal, timber and water are available. The ore shows values of $20 per ton. W. L. Knight of Pueblo is president, with H. C. Landran as manager.

MINERAL COUNTY.

The Humphreys mill, near Creede, has resumed operations after a temporary shut-down for overhauling and repairs, says Manager Fitzgerald.

The Corsair mine at Sunnyside, near Creede, has increased its output and is shipping twenty-five tons of ore a week.

MONTEZUMA COUNTY.

(Special Correspondence.) — The East Mancos G. M. Co., Mancos, Colo., will install an aerial tramway from the mine to the summit between Montezuma and La Plata counties, and the ore hauled from there by teams to the railroad in Hesperus.

Mancos, Aug. 10.

OURAY COUNTY.

It is reported that the Humboldt mine, near Ouray, will be tapped by a mile-long tunnel within the next year. The tunnel, which will start near the Revenue tunnel's portal, will cut the veins of the Humboldt group from 2000 to 2500 feet from the surface, and a mill will be built at its mouth to concentrate the ore.

A strike of free milling gold ore is reported in the Bobtail mine, owned by the Barstow M. Co. and in Red Mountain district, 3 miles west of Ironton. The strike was made 2300 feet from the mouth of the tunnel at a depth of 2000 feet from the surface. The ore body is 14 feet in width. Superintendent J. Geisel says the tunnel was driven into the mountain on a low-grade body of ore 3 feet in width, but for the past year the ground has been wet and hard to hold. Finally it was decided to drive across to the opposite wall of the vein, in the hope of bettering the situation, with the result that this shoot was found. Preparations are being made to build a 100-ton mill.

PARK COUNTY.

At Tarryall the Richmond stamp mill has been improved and will be in full operation by September 1. The Wolverine M. Co. has ore on the dump ready for treatment. Others are also prepared for delivery of ore to the mill.

SAN JUAN COUNTY.

Work has been resumed on the Silverton Girl, an extension of the Ridgway in Maggie gulch, near Silverton, by H. Sherman and A. S. Sturgeon.

T. Boyle and L. W. Russell of Durango have bought a half interest in the Crystal group of claims at Bear creek, near Silverton.

J. Gordon and A. Sturgeon have been given another lease on the North Star, this time between the third and fourth levels.

SAN MIGUEL COUNTY.

Five pack trains of eighteen mules each and three six-horse wagons are required to transport the product from the Tomboy mills, near Telluride, to the railroad, says the San Miguel Examiner. The concentrates average shipments of twenty-five cars (300 tons) per week. In both mines and mills 400 men are employed. The company is increasing its holdings, both in Telluride and Savage basin, says Manager Herron. A block of ground was bought last week in East Telluride, and the shipping station at Pandora will be moved there, the railroad company building a switch for use of the Tomboy Co.

J. H. Litchfield, manager of the Double Eagle group, in Bridal Veil basin, near Ophir, says driving the tunnel is progressing. Several veins have been cut by the bore, which is being driven on the Atlanta vein. When the Double Eagle vein has been cut, more men will be put on development and the ground opened up. The company proposes building a small mill this fall for the treatment of ore on the dump.

The Tidal Wave M. Co. reports work progressing on its properties above Ophir, near Champlin gulch. G. Pickett is superintendent.

TELLER COUNTY.

G. E. Righter, operating on southwest slope of Squaw mountain, near Cripple Creek, reports opening a 4 foot vein near the surface which assays $8. He is arranging to build a cyanide mill.

The Big Twenty M. Co., owning and operating ground on Grouse mountain, near Cripple Creek, is equipping its tunnel with a plant of machinery for development work. The tunnel will be driven ahead to cut at depth of 1000 feet a number of veins that have been opened in shallow workings on the hill and which show good values.

Manager A. Wagner of the Pharmacist Con. M. Co. of Cripple Creek, in his annual report says the inauguration of the leasing system has been very satisfactory, and that its operation through another year will leave them in a position to start work on company account. The lessees on the north end, blocks 1 and 2, have done 600 feet of drifting, crosscutting and stoping, producing high-grade ore. Crosscutting is in progress to cut the east and west vein. The management through the operation of this lease has been able to sink the Helm shaft 200 feet deeper, a total of 400 feet. The lessees on blocks 3 and 4, on the south end of the claim (the old workings), have done 400 feet of drifting and stoping and a large amount of ore has been shipped. The main shaft is down 660 feet, and it is intended to secure a lessee for this portion of the mine who will sink at least 200 feet more.

Superintendent G. Jordan started operations at Gillett on the Summit tailings dump last week. The material is said to run $7 per ton and the cyanide plant will treat forty tons per day.

Superintendent F. R. Davis of the new cyanide mill on the Ingham mine, near

Cripple Creek, started operations last week. The lessees expect to get returns of $6 in gold per ton.

W. E. Driscoll of Goldfield has a lease on the Black Diamond No. 2 and the Snowbank claims of the Ross-Lewin-McIntyre ground, on east slope of Big Bull hill, near Cripple Creek. The shaft on the Black Diamond is 200 feet deep, where a vein 4 feet wide was cut during sinking. It is low-grade oxidized ore and considered that it can be readily treated by the cyanide process. It is intended to build a cyanide mill capable of treating thirty-five tons per day.

The official measurements of the Cripple Creek drainage tunnel for July show 782 feet driven, which is 100 feet more than was made in June; 2'7 feet were driven from the southwest heading from the El Paso main shaft at 600 feet, 148 feet from the east heading of No. 2 shaft and 132 feet from the west heading of the same shaft, and 286 feet from the portal heading northward. The remaining ground to be traversed amounts to several hundred feet, which is expected to be broken out by August 15th.

The output of Cripple Creek district for July reached a total of $1,886,900. The smelters, while not treating as much as during other months, had a higher general average than ever before, says the Cripple Creek Times. The Dorcas mill also treated a high grade of ore. An added feature was the treatment of cyaniding ores. There were treated 2800 tons by this process, the total amount realized being $13,200. The following figures show details of the output:

	Tons.	Aver. Value.	Total Value.
Smelters	11,000	$65	$715,000
U. S. R. & R. Co.	21,000	24	504,000
Telluride	6,100	27	164,700
Economic	3,600	26	93,600
Portland	9,000	30	270,000
Dorcas	2,800	38	106,400
Globe	2,000	5	10,000
Gillett	400	3	1,200
Cyanide plants	400	5	2,000
Totals	56,300	$26	$1,866,900

At Cripple Creek, on the 10th inst., 3000 miners went out on strike. All the principal mines except the Portland, C. K. & N., El Paso, Strong and Gold King are closed down. It is expected that all union miners in the district will be called out in order to stop shipments, not only to the United States R. & R. Co. mills, but also to the smelters operated by the American S. & R. Co. because of its refusal to grant an eight-hour day at its Denver smelter.

J. F. Burns of Colorado Springs, president of the Portland G. M. Co., says the 100-drill compressor has been set up in shaft No. 2 at Independence. They will resume sinking in all the shafts. No. 1 shaft is 1130 feet deep; No. 2 shaft, 1290 feet, and No. 3 shaft is 1300 feet deep. Levels will be run out every 100 feet. The production of the Portland in July was 8000 tons of a grade of ore running from $25 to $30 a ton. As to the leasing of the Morse group, Burns stated the company had divided the north thirty-five acres into twelve blocks, which would be leased only to depth of 250 feet; all ground below that point being reserved to the company. The ground to be let out extends to the south line of the Vanadium claim and takes in No. 3 shaft, which, however, will not be leased. There is one shaft 150 feet deep on the Hawkeye and three of like depth on the Wisconsin claim, which will be given over to the lessees.

S. S. Bernard of Colorado Springs, president of the El Paso Con. G. M. Co., operating on Beacon hill, Cripple Creek, says the drainage tunnel is progressing and the drainage of the mine will begin soon. The mine produced 1200 tons of ore in July, the ore coming from above the water level.

The Cripple Creek Con. M. & M. Co. has been incorporated by Boston, Mass., men, and they have acquired twenty acres of patented ground on Gold hill and Howell hill, southeast of Victor, and a lease on the Rocky Mountain mine, on the west slope of Beacon hill.

IDAHO.

BLAINE COUNTY.

The Minnie Moore M. Co., near Hailey, has been retarded because of the strike of smeltermen at Denver, Colo., to which smelter shipments were being made. All the bins at the smelters being full of ore no more can be accepted until the bins are emptied.

BOISE COUNTY.

The Gold Coin M. Co., J. H. Emery of Idaho City, president, will put up a 5-stamp mill this fall at their mines near the Washington mine, and put a 100 H. P. dynamo on More creek, 1¾ mile from the mine, next spring. Work in the shaft, which is down 50 feet, will be resumed this month. When it reaches depth of 150 feet stoping will begin and the shaft continued down. Work will also be started in a 1500-foot tunnel to cut the Blue Bell at depth of 648 feet vertical and 700 feet on the dip of the ledge. It will be started as soon as the mill is up, says the Idaho World. The mill and machine drills will be run by electric power as soon as the plant is in.

CANYON COUNTY.

A one half interest in the U. H. Clark coal mine near Marsh, above Emmett, has been sold to J. Smith, J. C. Hayes, H. H. Quarles and H. W. Hart, who have put on men and started taking out coal. One crew will work in the tunnel to supply immediate demands for the coal, while another will drive a new tunnel 7 feet lower than the old workings, in which a fair quality of coal has been found at depth of 15 feet from the surface. The first tunnel will be abandoned as soon as the latter has been opened up, on account of poor timbering and improper drainage; the two will be connected, however, in order to furnish a circulation of air.

Manager M. M. Gibson says he will resume work on the Grant and Globe groups, near Idaho City, this week. The ore will be treated by cyanide process. The Globe tunnel will be extended 100 feet to cut the ledge. The Globe carries gold but no copper. The Grant tunnel is in the foot wall of the ledge. The Grant carries gold, copper, lead and silver.

CUSTER COUNTY.

Five miles from the mouth of Jordon creek, near Custer, a group of fourteen claims are being developed by the Bismark Mountain M. Co. A mill will be in operation this fall. Adjoining the Bismark on the east, the Sunset M. Co. is developing a group. A 100-ton mill is being put up, which is expected to be in operation by Sept. 1. The ore can be delivered from the mine to mill through a tunnel. The company also intends to put in an electric power plant for lighting purposes.

The air compressor at the mines of the White Knob C. Co., near Mackay, was started up this week, and it is expected to drive ten machine drills at an altitude of 8000 feet. The 900-ton smelter will be ready to "blow in" by Sept. 1st.

IDAHO COUNTY.

At Roosevelt, Moore & Campbell, owners of the Wisdom group, with Finch & Campbell of Spokane, Wash., have bought the Root & Fanburg group, between the Sunnyside and the Lightning Peak. They have put men to work on a 700-foot tunnel.

R. W. Purdum, manager of the Sunnyside mine, near Roosevelt, reports the ore bodies being blocked out in the mine. He has bought several pieces of adjoining property, the Wayland fraction, joining the Sunnyside, being among the number. Superintendent Abbott also has men preparing the ditch and ground for the installation of the 40-stamp mill.

Manager H. D. Rankin of the Rankin M. Co., on Rapid river, near Warren, reports the reduction works began operations this week. The electric plant is in operation.

The Big Creek G. M. Co. has bought two groups of mining claims in Big creek section of Thunder Mountain district, near Roosevelt. The headquarters of the company are at St. Louis, Mo.; W. M. Lucas, president. On the Logan Creek group, 200 feet of tunnel work has been done, and a body of ore that averages $15 per ton has been opened.

LEMHI COUNTY.

The machinery for the Gold Dust M. Co., of which R. A. Hasbrouck of Salt Lake City is manager, is being set up. It includes a 10-stamp mill with steam power and an electric light plant. Hasbrouck says the mill will crush forty tons per day, the stamps weighing 900 pounds each. The capacity of the mill will be enlarged as rapidly as development will justify. The mine is near Salmon City.

SHOSHONE COUNTY.

F. W. Bradley of San Francisco, Cal., consulting engineer of the Bunker Hill & Sullivan mines at Wardner, says, by reason of the recent decree of Judge Beatty, that portion of the extralateral rights of the Bunker Hill claim that has been tied up in litigation with the Last Chance claim was liberated and the mine opened. That portion of the mine opened by the Kellogg tunnel showed good ore. One hundred additional workmen will be placed in, making a total employed of 500. Added to this increase in the mines, they are preparing to make improvements at the Tacoma smelter. A bag house, at cost of $75,000, will be built, and a roaster, to cost $25,000.

It is reported that the Rockefeller interests, with C. Sweeny of Spokane, Wash., have formed the Federal M. & S. Co. to control the Cœur d'Alene lead mines and engage in the smelting business. J. A. Finch of the Standard and Mammoth mines, which will go into the combine, is interested. The deal will take place in the Rockefeller mines (the Monte Cristo) and the Everett, Wash., smelter, which are owned by them.

The Standard M. Co. owns a three-eighths interest in the Mammoth and the adjacent property, which is also under option to the Sweeny-Rockefeller interests. The consolidation would include also the Tiger-Poorman group at Burke and the Last Chance group at Wardner, owned by the Empire State-Idaho Co. The three properties combined are said to be producing about 60% of the argentiferous lead mined in the United States.

W. E. Snyder's Cow Creek placer claims, near Pierce City, have been sold to the Gold Creek M. Co.

The 10-stamp mill of the New Jersey G. M. Co. on the O. R. & N, 2 miles above Kellogg, is nearing completion, says the Spokesman-Review, and the machinery is being set up. The mill will be run by water power, and the 8300-foot flume is finished. The mill is but a short distance from the mine and a tramway will convey the ore. The mine is opened with a tunnel, which struck the ore body at depth of 200 feet. The ore is free milling, and a cyanide plant will treat the mill tailings.

INDIAN TERRITORY.

The Ketoowah M. Co. has been organized at Muskogee to develop mining property in the Ketoowah country, by J. C. Welch, T. P. Smith and W. T. Hutchings.

KANSAS.

CHEROKEE COUNTY.

The Badger M. Co., on Spring river, near the Missouri line, near Joplin, Mo., resumed operations this week after some delay in emptying its ground of water from the heavy floods of last spring. The company has two shafts, with 27 feet of ore developed in one and 14 feet in another.

MICHIGAN.

HOUGHTON COUNTY.

Houghton reports say it is expected the Wolverine mine, near Calumet, will yield 9,500,000 pounds of refined copper for the year, which began July 1. Last year construction cost $38,000.

Rock shipments from the Baltic mine, north of Painesdale, for month of July were 1500 tons more than for June and yielded a total of 797 tons of refined copper. Baltic No. 4 hoist is in operation.

Product for the Champion mine at Painesdale for the month of July was 734 tons of copper; and the Franklin mine at Hancock produced 376½ tons. At the Champion mill, another jig has been put in.

July output of Lake mines are reported as follows: Atlantic mine, at Atlantic, 311 tons 285 pounds; Trimountain mine, north of Painesdale, 425 tons; Winona mine, at Winona, 57 tons.

The beginning of surface work by the Calumet & Hecla management at the end of the property nearest the Centennial is thought to indicate that the company is to turn its attention to the Kearsarge lode, upon which it possesses an extensive outcrop north of Calumet, says the News.

MISSOURI.

JASPER COUNTY.

Joplin reports state that for the thirty-one weeks of 1903 ended August 1 the zinc output of the district amounted to 292,742,280 pounds, which has been sold for $5,010,285. The output of lead during the same period has been 54,910,140 pounds, which was sold for $442,220. The output of zinc is 37,983,000 pounds less than for the corresponding period of 1902, and the lead output 2,430,000 pounds below that 1902. Notwithstanding this decreased production, the output so far for 1903 has brought $405,991 more than was realized for all ore sold during the corresponding period of 1902, owing to the higher prices which have been obtained. As compared to last year the market is $2 per ton higher for zinc and $5 per ton higher for lead.

The Broken Four Co. started its new mill on the Aylor land at Alba this week. ——The New England mill is being moved to the Boston Get There ground, where Horning & Sapp will work the tailings piles.——The Acme L. & Z. Co. will prospect its tract of land south of Webb City by drilling.

The Anderson and Star mines on the Granby land at Joplin have been consolidated with the B. & H. M. Co.——Hohenshell & Co. report having struck a good run of lead on the American Bull Pup lease in 'Possum Hollow.

J. T. and W. S. Owen have a lease on twelve acres of the Consolidated M. Co. ground, north of Joplin. The company has drilled three prospect holes, two of which struck ore at depth of 60 feet and going to depth of 90 feet, and the company last week started to sink a shaft on one of their drill holes.

Gates, Nail & Martin have started their zinc mill on the Mitchell land, near Joplin, and are making thirty tons per week. Ore was found in two shafts at the 110-foot level. —— G. Brader, J. Marrs, C. Kier, E. Hansford and C. McGavern have a lease on twenty acres of the Rusk farm, north of Joplin, and are opening up their ground.

H. C. Holland of Indianapolis, Ind, has bought the Mulberry lease of the B. F. Horton land near Duenweg for $40,000.

C. D. Pratt of Joplin is sinking a new shaft at the Sassafras on the Midway tract. Pratt, by putting in heavier pumps, has succeeded in handling the water. —— T. Jones of Joplin and B. Collins of Bradford, Pa., are operating the Cottonwood Hollow mines near Joplin, and are sinking two new shafts. One is down 54 feet and the other 50 feet, expecting to reach ore at 70 feet ——Four drill holes have been put down on nine lots of the Connor land, west of the Lucky Budge, by J. B. W. Amsden, T. Sayer and J. Madeira et al. of Joplin. Three of the drill holes showed ore from 140 to 200 feet. The fourth hole showed 16 feet of sheet ground. A shaft is being sunk.—— N. B. Lichliter of Joplin reports drilling through ore from 45 to 95 feet on the Eclipse lease of the Aylor land near Neck City.

C. M. Christmas of Joplin, manager of the Missouri mine on Center creek, near Carterville, says a company has been organized to take hold of the Rush and Nebraska mines at Jackson Hollow, and they are repairing the Rush mill and will put up a new mill on the Nebraska ground.

The following companies were incorporated at Joplin last week: The Carrie Z. Lead & Zinc Co. by W. S. Zehrung, I. M. Bransfield, C. N. Crisman and H. S. Hurst; the Mamie B. M. Co. by I. M. Bransfield, C. Martin, W. S. Zehrung and J. N. Doty; the Chapman M. Co. by F. Nicholson, T. Chapman, C. and R. Burnes and B. Hurst.

LAWRENCE COUNTY.

At Stotts City the Keystone, C. C. C. and McFarlane mines report operations resumed last week. —— N. Larkin has moved a hoist from the Jack Davis mine on the Underwood, north of Stotts City, to the Small Hope, and says he will begin operations this week.

The output of mineral from the mines of Aurora for last week was reported the best in several months, but only two cars were shipped, on account of a car famine, which, if it continues, may close down some of the mines. —— Sinking has been suspended at the Sand Ridge mine at Aurora and drifting at depth of 330 feet started.

NEWTON COUNTY.

Woodcock & Sons, who bought the Cannonball mine at Granby, have put in hoisting machinery and are taking out zinc silicate.——Smith & Co. have cleaned out a shaft northeast of the Cannonball, naming it the Big Gun, and will develop it.——The 80 ton mill at the Globe M. Co., 1 mile west of Diamond, on the Ellis land, was started last week.

STONE COUNTY.

Elder & Co. have leased the Prince mill on the New York Zinc Co. ground at Galena and have begun active work.——The Battlefield mine has been drained and work resumed in several of the drifts.

MONTANA.

The report of the United States assay office at Helena shows total receipts for the month of July to have been $214,152.08, as compared with $217.760.46 for July, 1902. From Montana gold to the amount of $180,546 32 was received, against $172.501.95 for July, 1902, the principal producers being as follows: Fergus county, $68,740; Jefferson county, $10,818; Lewis and Clarke, $17,395; Madison, $28,081; Park, $19,639. This does not show the entire production of gold in the various counties, for, while the Fergus county product, which is principally cyanide, nearly all goes to the assay office, there are many mines in Lewis and Clarke and other counties that send most of their products to the smelters and none to the assay office.

FERGUS COUNTY.

In development of the mine of the Alder Gulch M. Co. in the Little Rockies, near Lewistown, high-grade shipping ore is being taken out. Twelve tons sent out last week netted the owners—Zortman, Putnam & King—$4000. The Alder Gulch mill is in operation, says Manager King.

FLATHEAD COUNTY.

Superintendent D. P. Bowers reports work at the Snowshoe mine, near Libby, going ahead. The concentrator is running steadily, the rains of last week having added to the reserve water which is stored to tide the mill over the dry season. At the mill there are 900 tons of

concentrates, partly sacked, to be shipped to the railroad at Libby. All work so far this season has been at the 200-foot level. The working shaft is 300 feet deep and that portion below the 200 is filled with water. Their equipment includes an electric lighting plant.

The Mustang Con. M. Co., operating in West Fisher district, on Great Northern mountain, near Libby, is running a tunnel to cut five veins which outcrop in its group and carry gold values. The tunnel is in 255 feet and within the next 100 feet the first vein is expected to be struck. The second vein will be cut at 560 feet on the Enterprise, and the fifth will require a depth of 1400 feet. J. Cameron is superintendent.

GRANITE COUNTY.

In Henderson gulch, near Phillipsburg, a dredger is to be installed to work old placer grounds, says Manager C. E. Van Barneveld of a Minneapolis, Minn, company. Of late years the Henderson placers have been worked in a small way by leasers, operating with sluice boxes and rockers. The fields are on the side of a long bar.

JEFFERSON COUNTY.

C. M. Hewett, at the High Ore mine, near Basin, reports a strike of ore. The tunnel was continued and the lead cut at a depth of 800 feet. Forty-three feet of concontrating ore is shown, and the width of the shipping ore in the face is not yet determined. The tunnel is in 2150 feet and a drift is being run west.

A gold strike is reported from one of the claims taken over by the Rose G. M. Co., near Jefferson City.

LEWIS AND CLARKE COUNTY.

(Special Correspondence)—The Argo Copper M. Co. is developing a group of copper claims 26 miles north of Helena, says Consulting Engineer F. L. Sizor. A concentrator with a capacity of forty tons per day has been built, and it is expected to be in operation this week.

Helena, Aug. 10.

The Jay Gould mines, under bond to the Standard Ore Co. of Helena, will be further developed. The Jay Gould is in Canyon Creek range, 20 miles north of Helena, and carries gold and silver. There is a large amount of tailings which, it is said, are amenable to cyanide, and these will be treated.

W. A. Simmons and A. Berquist of Basin have leased ground on the corner of Third and Chaucer streets, in Helena, for the purpose of sinking a shaft and following a lead of gold ore which is claimed to run northeast from the lime quarries, 300 feet distant, on Chaucer street.

MADISON COUNTY.

The Damours M. & M. Co. has been incorporated under South Dakota laws, with J. B. Woodburn, L. H. Bearse, W. C. Bennett, E. T. Howes, A. P. Bassett and M. Speight of Springfield, Mass, as directors, and C. E. Damours of Virginia City, Mont., as manager. The properties of the company are at Summit, 8 miles south of Virginia City, and comprise fifteen claims, including the Ptomey, Damours and Bryson lodes, which are said to contain good bodies of milling ore.

NEVADA.

ESMERALDA COUNTY.

(Special Correspondence.)—S. R. Wasson and E. A. Montgomery are reported to have located a large deposit of native alum about 12 miles north of Silver Peak and 4 miles from the proposed railroad from Sodaville to Tonopah. The deposit has been exposed for 1000 feet in width, and it is said that the indications are that it is much wider. The deposit also contains native sulphur.

Silver Peak, Aug. 10.

LINCOLN COUNTY.

In Crescent district, 18 miles west of Searchlight and 14 miles northeasterly from the Ivanpah terminus of the Barnwell branch of the Santa Fe Railroad, G. Simmons, who owns the turquoise mines, has bought the Tiger gold claim and is having a shaft sunk by contract, says the Searchlight. There is a body of $8 ore opened.——R. D. Kinney has done several hundred feet of work on a ledge northeast of Crossman Springs that assays well in silver, with some gold.

The Mohile and Copper Chief mines, in Yellow Pine district, have been bonded to O'Meara & Lynch of Tonopah, Nye county. The two claims adjoin and are 3 miles northeast of Sandy. They contain copper values.

A new shaft is being sunk on the coal deposits 40 miles from Pioche.

STOREY COUNTY.

At the Con. Cal. & Virginia, at Virginia City, the superintendent's report for week ending August 8th shows on 2150-foot level, the southerly drift from end of east crosscut from winze from 1950 level was advanced 8 feet in quartz, of low assay value, and porphyry; over the seventh floor northeasterly drift from three-compartment raise from this level, worked on the twelfth, thirteenth and fourteenth floors in the north stope and extracted ore of second grade. In the main shaft, have taken out the discharge column of No. 2 elevator between the 1750 and 2150-foot levels, as it is no longer needed between these levels. No. 1 elevator and the three Reidler pumps were, on the 5th inst., put in successful operation of lowering the water, which is now down to 2250-foot level station. The Cornish pumping system is being taken out below the 2150-foot level, and the shaft compartments are being cleaned. Total extraction of ore for week, fifty-seven cars, assaying on basis of gold value $10 04 per ton.

At the Seg. Belcher at Gold Hill, for week ending August 8th, on 1100-foot level, the east crosscut near the south line was continued 9 feet; total 675 feet; face in porphyry. The electric blower is running and furnishing a current of cool air. The work of enlarging the joint main drift from the Overman north line north of the Belcher incline is progressing.

A. C. Kyle, superintendent of the Alpha and Exchequer mines at Virginia City, says he is preparing to resume work there. Large bodies of low-grade gold-bearing rock are said to exist in the Alpha and Exchequer, which, with the reduced rates for mining and milling made possible by the introduction of electrict power, it is expected can be handled at a profit.

Arrangements have been made by the mining companies on the Comstock, near Virginia City, and President Leonard, of the Comstock Tunnel Co., in regard to putting the Sutro tunnel in repair.

WHITE PINE COUNTY.

It is reported the Grand Deposit C. M. Co. has taken a bond on the Victoria copper group of claims, in Granite Mountain mining district, near the Bimetallic and Jupiter groups, 40 miles northeast of Cherry Creek, says the Cherry Creek Miner.

The Wide West M. Co.'s mill near Cherry Creek is completed and in operation, says Superintendent Leishman.

The Pick & Gad M. & M. Co. was incorporated last week in New York City, to operate the Pick & Gad mine at Cherry Creek, by J. Howard, C. Wah and J. Callahan of Cherry Creek. The Pick & Gad carries free-milling gold, with average values $10 per ton, in a 4 foot ledge, on which a 155-foot shaft has been sunk.

NEW MEXICO.

GRANT COUNTY.

The owners of the Aztec group at Pinos Altos will build a 60-ton concentrator for use of Lessee W. McAllister. The concentrator will handle the low grade ores of the Aztec, which consist of silver sulphides and gold, says the New Mexican. The engine, boiler, timbers and other material of the Aztec mill, north of Silver City, will be removed to south of Pinos Altos. The concentrator will have rolls, screens, jigs and dry concentrating table. The plant is expected to be in operation by November.

The B. F. Copp half interest in the Virginia mine in the Burro mountains, near Silver City, has been sold to L. P. Deming of the Alessandro M. & M. Co. Deming has miners at work sinking a shaft to connect with a 30-foot winze which is in a drift off the main shaft.

GUADALUPE COUNTY.

South of Tucumcari several copper prospects are being developed, says the New Mexican.

OTERO COUNTY.

The Three Bears M. Co. is developing its holdings at Jarilla under Manager F. B. Schermerhorn. A 4-foot vein of ore has been cut at the 200-foot level that runs $20 per ton in gold and copper values. Philadelphia, Pa, men are interested. The shaft will be sunk to a depth of 1000 feet ——A well is being sunk to a depth of 909 feet at Jarilla to furnish water for the placers, and is down 200 feet. G. F. Moffit is superintendent.

SIERRA COUNTY.

Work will be resumed on the Confidence mine at Fairview, says Superintendent T. Scales, who is rebuilding the road to the mine.

SOCORRO COUNTY.

The Milling & Mining Dividend Co. will resume operations this month at Estey City. The company is reported negotiating for more claims in the district.

OREGON.

BAKER COUNTY.

The Taber Con. Fraction, on the lode between the end lines of the Eureka and the two fractions adjoining the Columbia mine near Sumpter, was bought last week by the Geiser-Hendryx I. Co. for $25,000.

The testing mill and sampler of McEwen, Arthur & McEwen, at Sumpter, is in operation.

It is proposed to put up a mill this fall, says Superintendent Cable of the Adelene mine in Rock Creek basin, near Sumpter.

GRANT COUNTY.

Work at the Black Jack mine, south of the Oregon Monarch mine, near Granite, is progressing, says Superintendent Sheedy. Last week work was started on a number of buildings. Lincoln, Neb, parties are interested.

G. W. Dart, who has leased the Humboldt ditch for placer mining, has had to suspend operations because of the lack of water. The bedrock has been washed and a satisfactory cleanup made, reports Dart.

JOSEPHINE COUNTY.

It is intended to place a 40-stamp mill on the Benton mine, on Whiskey creek, in the Mt. Reuhen district near Grant's Pass this fall, says the Courier. There is plenty of water power for the operation of mill and electric plant.

The Gold King mine, on Josephine creek near Grant's Pass, has been bought by a company composed of A. J. Roe, D. T. and J. A. Evans, of Fort Worth, Tex., and M. Marks, of Grant's Pass, who is superintendent. The new owners will put on a complete equipment of mining machinery, with stamp mill, pumping plant, etc. Men will be started to work on the main shaft.

MORROW COUNTY.

A coal mine is being opened up on the headwaters of Willow creek, 21 miles southeast of Heppner, by the Heppner Railroad & Coal Co. Bunkers that will contain forty-five tons have been built, and work is in progress on the railway track to connect with the O. R. & N. into Heppner.

SOUTH DAKOTA.

LAWRENCE COUNTY.

The annual report of Manager Thompson of the Columbus Con. G. M. Co., operating northeast of Central City, shows that the amount of work done is 6089 feet and the total sum expended by the company in labor, tools, etc, totaled $191,923. On the Columbus claim the old shaft has been sunk to a depth of 300 feet; 1078 feet of crosscuts have been run from the 200-foot level, which shows four veins which assay from $1 to $8. The Columbus shaft house has been rebuilt and enlarged and a 12-drill air compressor and double-drum hoist put in. On the Dalton group 1730 feet of drifts, tunnels and crosscuts have been run, blocking out ore. On the L. & F. Claims 2461 feet of tunnels and drifts have been run. There have been run 625 feet of tunnels and cuts on other of the company's properties. In addition the company has built wagon roads and made other improvements. They have added to the original purchase the Portland mill, which has been rebuilt and enlarged to treat seventy tons of ore per day. The mill is saving 80% of the values of the ore. It is proposed to increase their treating capacity by building an amalgamation and cyanide mill of 1000 tons daily capacity.

UTAH.

In the ore and bullion market the month of July closed on settlements aggregating $1,829,250 (this independent of the product from the furnaces of the copper smelters). Compared with the corresponding month of 1902, this shows an increase of 20%, though the producers are sending out only such ores as are necessary to maintain the payroll and providing for dividends while waiting for a better metal market. However, the tonnage of every camp shows an increase over July, 1902. The most noticeable increase has been in the tonnage of copper-bearing rock. The output of copper bullion carrying gold and silver at the furnaces of the "independent plants" during the month of July was reduced to 2,511,984 pounds (from 2 546,686 pounds for June), the shrinkage due largely to an interruption at the Highland Boy, during which a number of changes were made, says the Salt Lake Tribune.

	Pounds.
Bingham Con	759,544
Highland Boy	1,020,680
United States	731,760
American S. & R. Co	1,200,000
Total	3,711,984

Of this class of bullion a material increase is expected during the last half of the year. It is said that at the Bingham Con. the fourth furnace will be blown in before Sept. 1. The Highland Boy will increase its capacity to 750 tons of ore daily. The United States Co. will put in a sixth furnace, and it is expected the Tintic M. Co. will have its furnaces under fire before the first of the year.

BEAVER COUNTY.

Two of the gasoline hoists for the Royal C. Co.—one 15 H. P. and the other 40 H. P.—are on the ground to be set up at the Montreal group, near Milford.

JUAB COUNTY.

Shipments for the month of July from Tintic district amounted, in cars of ore, to:

Bullion-Beck	41
Carisa	10
Centennial-Eureka	121
Eureka Hill	10
Gemini	29
Grand Central	86
Mammoth	10
Star Con	12
Uncle Sam Con	17
Victor	12
Yankee Con	20
Seven others	16
Total	384
Iron ores:	
Black Jack	59
Dragon Iron mine	74
Noon Iron mine	13
Total	146
Concentrates:	
May Day	4
South Swansea jigs	1

SALT LAKE COUNTY.

The Cluster M. Co. holdings at Bingham have been taken over by W. M. Ferry and M. H. Walker. The Cluster group lies between the United States M. Co. ground on the west and the Bingham Con. Dalton & Lark group on the east. The ores show values in lead, gold and silver. To tap the ore bodies at vertical depth of 600 feet, a tunnel is being driven a distance of 1100 feet by Superintendent C. A. Falco, of Bingham.

The management of the Mystic Shrine mine of Bingham has bought the St. Elmo, a patented location adjoining the company's territory on the south. Within the next 125 feet it is expected the main tunnel, in 725 feet, will reach the main ore body, says Manager E. W. Young. The equipment has been increased.

SUMMIT COUNTY.

At Park City it is reported work will be resumed at the Constellation mine, of which H. Sutton is superintendent. It is claimed that the Constellation carries an extension of the Ontario veins. It is intended to do development work on the 350-foot level.

Work has been started on the Donovan group, recently incorporated. The mines are northwest of Park City, near the Keith & Fluelling group; the company is composed of Iowa and Utah men.

Superintendent C. L. Rood of the Ontario mine, near Park City, says preparations are being made to build a concentrating mill. On the 2000-foot level of the Ontario a compound duplex pump is being set up, which will be in readiness in case of emergency, should a large volume of water be cut. The pump was formerly on the 1300-foot level and has a capacity of 1000 gallons a minute.

TOOELE COUNTY.

Work has been suspended at the Old Colony mine, near Stockton, for an indefinite period, says the Mammoth Record.——Work at the Manhattan mine, which has been suspended for a few weeks, has been resumed by T. Fairchild under a contract to sink another 100 feet.

UINTA COUNTY.

Work is reported progressing at the twelve wells now drilling near Evanston, and two or three are expected to strike oil this week. The Atlantic & Pacific Co. has completed well No. 2, estimated to yield fifty barrels per day. None of the wells in the field have been shot as yet, owing to lack of storage capacity. Six 1000-barrel tanks are on the ground at Spring Valley for the Atlantic & Pacific Co, and a test will be made of No. 1 and No. 2 wells.——The American Con. Co. are nearing the sand in their well No. 3, and have drilled 200 feet on No. 1 well. Another derrick is being built on the same section.——Work at the Jager well No 2 has been suspended. About 1000 barrels of oil was pumped from their well No. 1, which is a twenty-five-barrel well. ——The Bettys Oil & Dev. Co. has been shut down for six weeks waiting for casing ——The Michigan-Wyoming Oil Co. has reached a depth of 1200-feet, but is having trouble with the water.

WASHINGTON.

OKANOGAN COUNTY.

J. M. Hagerty, principal owner of the Ruby mine, Okanogan district, near Loomis, has bought the Golden Zone concentrator and will put it on the Ruby and expects to be treating ore before Sept. 1. While the upper workings are supplying ore it is the intention to start a main tunnel at the base of the mountain, several hundred feet below the other tunnel. There is a quantity of low-grade ore on the dump that can be concentrated.

Work was started last week at the

Crystal Butte mine on Copper mountain, near Chesaw. Several buildings are being put up, and when these are finished men will be put to work in the mine taking out ore. The concentrating plant is being overhauled and repaired, says the Spokesman-Review. Men are at work on the Delate, owned by the Interstate M. Co., and the number will be increased. They will take out ore for treatment in the mill, which will also do custom work. Several other properties are starting up and will furnish ore at the mill. O. P. Anderson is vice-president and manager of the company and H. Thompson superintendent. The Crystal Butte is leased by the Interstate Co. from the Crystal Butte M. Co. of Spokane.

M. A. Smalley, manager of the Wyandot M. Co., says arrangements are being made to again start work on the Oregon mine, 7 miles west of Chesaw. There are three claims in the group.

STEVENS COUNTY.

The month of July showed considerable activity in the marble industry in Stevens county, says the Spokesman-Review. Two new plants have been installed, one including a channeler now in operation on the Standard Marble Co.'s ground, 4 miles east of Colville, and a drilling plant on the properties bonded by J. A. Finch et al. of Spokane. The Finch group (the Queen of Sheba) is 16 miles north of Colville. The Crystal Marble Co., operating near Addy, shipped five carloads of rough stone to its works in Spokane during the past month. The Jefferson Marble Co., on Clugston creek, has men at work running its channeler and has twenty carloads of marble ready for shipment. They have shipped two carloads to Buffalo, N. Y. The United States Marble Co. has put out a carload of green marble for New York. A number of other smaller properties are doing development work. It is estimated that the marble industry of Stevens county is giving employment to 200 men.

In the injunction suit of M F. Gibson vs. Indian Agent Anderson, Judge Hanford of the United States Circuit Court at Spokane has rendered a decision upholding Agent Anderson in expelling Gibson from the Spokane Indian reservation, where the latter had located mining claims. Gibson contended that under the general law he could locate claims previous to the President's proclamation withdrawing the land and hold them in spite of that order.

WYOMING.

LANDER COUNTY.

C. Walter, manager and director of the Belgo-American Drilling Trust, says since buying the Henderson wells in the Popo Agie fields, near Lander, eight new gushers have been struck. The news was not made public, as the wells were plugged as soon as the oil flow was encountered, and will remain plugged until the completion of the proposed railroad into tbat section. The railroad will go west from Casper, instead of Guernsey, the Burlington terminus in Wyoming, the Northwestern railroad having entered into an agreement with the company. Estimates on the work have been made on the construction of the line, which will be 165 miles in length.

FOREIGN.

BRITISH COLUMBIA.

BOUNDARY DISTRICT.

This week the four furnaces at the Granby smelter at Grand Forks will be blown out, for the purpose of connecting up the two new furnaces, which will require about ten days, when all six will be operated. In the meantime ore shipments from the company's mines will be discontinued, says Superintendent Williams, but the miners will continue work, as there is storage room in the mines for a large amount of ore. When shipments are resumed they will be at the rate of 2,200 tons daily. The Granby smelter at Grand Forks, for the week ending Aug. 1st, treated 8832 tons, making a total of 186,307 tons for the year. Shipments were:

	Week.	Total.
Granby	8,295	197,780
Mother Lode	3,100	58,830
Snowshoe	1,560	33,772
B. C.	600	18,475
Emma	....	10,016
Sunset	256	8,481
Providence	....	634
Oro Denoro	320	620
Athelstan	60	435
Elkhorn	....	129
Totals	14,191	328,171

This makes the output for the month of July 57,492 tons.

Two more gold bars from the Waterloo mine in Camp McKinney were sent out last week, valued at $5,120, making $8000 produced in forty days' running. Operations were started June 16, and with five stamps the mill is treating twelve tons a day. In addition to the gold bullion the mine has received $3630 net on shipments of high grade ore to the smelter, and has another car which will be shipped this month, in addition to a carload of concentrates. Manager D. Clark is planning to add to the mill.

NELSON DISTRICT.

G. H. Barnhardt has leased the Porto Rico mine from the Canadian Pacific Ex. Co., Ltd., of London, England. He will start work this week. The mine is a free milling proposition at the head of Barret creek, near Ymir.

ROSSLAND DISTRICT.

The output from the mines of Rossland Camp for the week ending August 1st were slightly below normal, largely due to decreased consumption at Le Roi smelter, where the number of furnaces in operation have been reduced pending increased coke supplies from East Kootenay, says the Rossland Miner. Construction work at Le Roi 2 and the White Bear mines is reported progressing. Shipments from Rossland camp for week ending August 1st and for year to date are as follows:

	Week.	Year.
Le Roi	3,930	108,185
Centre Star	1,530	48,415
War Eagle	1,080	34,335
Kootenay	420	4,186
Le Roi No. 2	630	16,542
Velvet	....	3,376
Giant	....	698
Jumbo	150	542
I. X. L.	....	70
White Bear	....	297
O. K.	....	25
Homestake	....	90
Totals	7,770	216,762

This gives the output of the month of July at 21,340 tons, as compared with 36,360 tons for June.

The Velvet mine, near Rossland, has suspended operations indefinitely. Manager W. Gray says the Velvet is unfortunate in respect to transportation. The charges for transporting the ore from the mine to the railroad are excessive, owing to the distance and altitude, and the charges for bringing in supplies equally heavy. Under existing conditions ore is not payable that does not carry over $20 per ton. The Velvet has bodies of ore blocked out running from $12 to $20. During the past ten months the mine has shipped 5000 tons of high-grade ore.

SLOCAN DISTRICT.

The Comstock mine, near Slocan City, is being worked by W. Hunter with ten men. Ten inches of ore has been exposed on the surface between No. 4 and No. 5 tunnels. —— The concentrator at the Wakefield mine is being remodeled and when completed will have capacity of 150 tons per day.

The amount of silver-lead ore being shipped through Kalso from Slocan mines is reported daily increasing. Want of miners is hampering operations.

YALE DISTRICT.

H. Stanislawsky, manager of the Mount Baker & Yale M. Co., at Yale, says he will put a 60-stamp mill and concentrator on the company's property, 5 miles south of Yale. The ore is in a porphyry dike 80 feet wide. There are eighteen men on development work. There is a wagon road built down to the Fraser river and a cable line across it with sixty-four tons capacity.

CANADA.

ALBERTA.

Development work is progressing on the coal properties of the International Coal & Coke Co., 3 miles west of Blairmore, and extending from the railroad south a distance of 7 miles, says Manager A. R. Paulson. Two main entries have been started at this point, wagon roads built, the erection of tipples prepared for and surveys run for building side tracks, etc., to connect the mine with the railroad. The company has laid out yards for a large number of coke ovens and is building a few ovens in which to test the coking qualities of the coal from their various seams. Shipments of coal have begun and two carloads are being taken out daily in course of development work.

ONTARIO.

(Special Correspondence.)—The Black Bay M. Co., on a peninsula east of Port Arthur, are sinking on a copper prospect, which is reported to give very encouraging results, the ore running from $7 to over $60 per ton. The rock contains native copper. A shaft is being sunk, now down 118 feet, and a level started at 76 feet from the surface. The company is composed of Willmar, Minn., men, G. P. Karwand, president. Several of the directors recently visited the mine, and have decided to increase the plant by the addition of larger hoisting machinery and to continue developments to a greater depth.

Willmar, Aug. 9.

A. P. Coleman of the Bureau of Mines reports the Helen iron mine in Michipicoten district being opened up with satisfactory results. They are raising 1400 tons of ore daily.——At Sudbury and Copper Cliff, the nickel camps, operations are active. The Canadian Copper Co. is reconstructing its plant. For the present the Creighton mine, one of their most important nickel mines, is closed in order that all the men may be utilized in the reconstruction work. —— The Hutton iron mine range, north of Sudbury, is also being worked.

MEXICO.

CHIHUAHUA.

The Stilwell M. Co. has work started on its Germania mine, adjoining the Two Republics, near Parral. A general sample from the surface gives an average assay of sixteen ounce silver, says the Enterprise.

The Guazapares M. Co. has its mines at Guazapares under option of sale and is timbering its shaft. If the sale does not go through the company will start operations September 1. The leaching plant of forty tons daily capacity is reported to work satisfactorily in treating their gold-silver ores.

The Pittsburg-San Jose R. & R. Co. has two-thirds of the rails for its railroad from the Gavalana mines to the mill at San Jose del Sitio hauled out from Palomas station on the Mexican Central, about 90 miles, and track laying is progressing.

JALISCO.

The Tula Iron Co. has been organized under New Jersey laws to take over the Tula Fereria iron works and mines in Sayula district, 60 miles south from Guadalajara. The company will equip and develop the mine and improve the plant. It is proposed to build a hydraulic plant to operate the mill and mines, which are 20 miles apart. The first change will be to substitute traction engines for the mule pack trains.

MEXICO.

The El Oro M. & R. Co. at El Oro, owned by English parties, has a 100-stamp mill in operation, to which the directors of the company have decided to add another 100 stamps. Their principal operations are on the San Rafael vein.

At the northwest end the El Oro M. & R. Co.'s ground is adjoined by the Esperanza M. Co. The Esperanza is working on the same vein as the El Oro and has 120 stamps dropping.

MICHOACAN.

West of the Esperanza mine, in El Oro district, the Dos Estrellas mine at Tlalpujahua has forty stamps dropping. An 80-stamp mill is being added to the equipment. The Dos Estrellas veins carry high-grade values in gold and silver.

SONORA.

(Special Correspondence) —The new 40-stamp mill of the Zubiate M. Co. at Zubiate were dropped for the first time on the 6th inst. The stamps weigh 850 pounds each. The mill is equipped with six concentrators, ten pans and five settlers. A modification of the Washoe process is used. The mine is opened through a three-compartment shaft, down 650 feet.

Zubiate, Aug. 7.

The Caliche Mountain M. Co., Tener Bros. & Balch principal owners, is developing a gold property 6 miles from Cerro Prieto. It has sunk two shafts, 700 feet apart, one 90 feet deep, the other 60, both in ore their full width. A tunnel is being run in on the vein to cut the shafts. The ore averages $10 per ton in gold.

The San Blas M. Co., which has taken over the San Blas mine, 45 miles northwest from Caborca, in Altar district, has been incorporated in Massachusetts. The property is a gold-bearing mine, with five veins, tbree of which were opened and operated by the "antiguos." The directors of the company are D. J. Brown, L. R. Godfrey, E. H. Beer, G. N. Rich, G. H. Miner, E. F. Gibbs and J. H. Trayne of North Adams, Mass., with J. A. Singey of Caborca general manager.

PERSONAL.

H. L. FRANK has returned to Montana from Europe.

J. A. DEXTER is in San Francisco, Cal., from Nome, Alaska.

J. B. FARISH, E. M., of Denver, Colo., is in San Francisco, Cal.

W. L. AUSTIN of New York City is at Copperopolis, Calaveras county, Cal.

H. T. HENDERSON, general manager of the Animas Canal R. W. P. & I. Co., has returned to Durango, Colo., from Denver, Colo.

C. H. LINDEY of San Francisco, Cal., has returned from a business trip to Portland, Or.

H. NEWELL of Salt Lake City, Utah, interested in Utah mines, is in San Francisco, Cal.

S. E. ROBBINS is superintendent of the Red Cross mine, near Omega, Nevada county, Cal.

ARTHUR LAKES of Denver, Colo., is examining mining property in Idaho and British Columbia.

W. J. RULE has returned to Central City, Colo., from an extended visit to Grass Valley, Cal.

G. J. MCCARTY, a mining superintendent of Sonora, Mexico, is in San Francisco, Cal., on business.

P. L. YOUNG of San Francisco, Cal., has gone to Halifax, Nova Scotia, where he will do mining work.

O. HERLOCKER is manager of the Highland G. M. Co., operating the Highland mine, near Sumpter, Or.

R. W. RODDA is at Lillooet River, B. C., on mining business and returns to Seattle, Wash., next week.

F. R. DAVIS is superintendent of the cyanide plant operating at the Ingham mine, near Cripple Creek.

R. R. LESLIE has resigned as superintendent of the Le Roi mine at Rossland, B. C., to take effect Sept. 1.

J. A. FINCH of the Standard and Mammoth mines, at Wallace, Idaho, is in New York City on mining business.

L. TOVEY, a mining engineer of Tomsk, Siberia, is in Denver, Colo., and will visit tbe principal camps of the State.

PRESIDENT N. TREWEEK of the Wabash M. Co., returned to Salt Lake City, Utah, last week from a trip East.

W. E. THORNE, E. M., has gone from San Francisco, Cal., to Siskiyou county, Cal., to examine mines near Yreka.

JAMES DOYLE, president of the East Mancos G. M. Co., Colo., returned to Denver Colo., last week from the mines.

F. L. SIZER, E. M., consulting engineer of the Argo Copper Mfg. Co., near Helena, Mont., is in San Francisco, Cal.

SUPERINTENDENT T. A. PATTERSON of the Pilgrim mine, at American Hill, near Nevada City, Cal., is in New York.

F. W. BRADLEY of San Francisco, Cal., consulting engineer of the Bunker Hill & Sullivan mines, is at Wardner, Idaho.

R. D. SEYMOUR, western manager of the Trenton Iron Co., has returned to Denver from New York and other Eastern points.

T. DERBY, superintendent of the Quicksilver M. Co. at New Almaden, Santa Clara county, is in San Francisco, Cal., on business.

H. F. MCFARLANE, owner of the McFarlane mine at Stotts City, Lawrence county, Mo., returned last week from a trip to Chicago, Ill.

B. W. BEGEER has accepted a position as assayer and metallurgist with the Trinity County G. M. Co., near Dedrick, Trinity county, Cal.

G. E. NOLAN, manager of the Nevada Engineering Works, has returned to Reno, Nev., from an examination of Butte Co, Cal., mining property.

B. F. BROUGH, of Toledo, Ohio, secretary-treasurer of the Wyandot M. Co., operating near Chesaw, Okanogan Co., Wash., is at the mines.

D. L. PARHAM, formerly with the Yellow Aster M. Co. at Randsburg, Cal., is foreman of the Gold Hill M. Co. at Gold Hill, near Tonopah, Nev.

G. E. VOORHEES, Jr., of Santa Barbara, Cal., principal owner of the Las Vigas mine at Coyame, in eastern Chihuahua, Mex, is on a visit to the mine.

J. MACFARLANE, general superintendent of the Cerro de Pasco mines in Peru, is in Utah on a business trip from the East, after which he will return to Peru.

C. WALTER, manager of the Belgo-American Drilling trust, operating in Wyoming oil fields, returned last week to Cheyenne, Wyo., from a trip to Belgium.

L. G. CARLETON of Cripple Creek, Colo., is superintendent of the leasing department of the Doctor-Jack Pot Con. G. M. Co., operating on Raven Hill, Cripple Creek.

RAYMOND WHINNERAH, millwright and engineer, who has been superintending repairs of the Mountain Pride mill,

Breckenridge, Colo., has returned to Denver, Colo.

A. C. KYLE, superintendent of the Con. New York M. Co., at Gold Hill, Nev., has been appointed superintendent of the Alpha and Exchequer mines, also on the Comstock.

PRESIDENT W. B. MUCKLOW of the Majestic Copper Co., returned to Hartford, Conn., last week from a visit to the mines of the company at Milford, Beaver county, Utah.

T. FISHER, formerly operating in Joplin district, Missouri, and also manager of the Olympia mine in northern Arkansas, is superintendent of the North American Lead Co. at Fredericktown, Mo.

S. B. WELD, late of Ricketts & Banks, New York, has associated himself with H. C. Parmelee, under the firm name of Parmelee & Weld, 1755 Arapahoe street, assayors and chemists, Denver, Colo.

F. J. STANTON of the Denver School of Mines, Deover, Colo., has returned from an examination of a group of mines on the lake fork of the Gunnison river, near the Bowerman find, near Waunita, Colo.

R. H. ANDERSON, manager of the B. C. and Oro Denoro mines at Summit camp, B. C., will be superintendent of the Le Roi mine at Rossland, B C., vice R. R. Leslie, resigned, to take effect Sept. 1.

F. W. OLDFIELD, late of the Palmarejo and Mexican Gold Fields Co., Chinipas, Chihuahua, Mex., sails from New York on the 18th as assistant to the local manager of the South American Development Co. in Ecuador.

F. H. PROBERT, consulting engineer for the W. B. Thompson Co. and the Coronado M. Co., has returned to Los Angeles, Cal., from an investigation of the mineral resources of the Arispe, Moctezuma and Sahuaripa districts of Sonora, Mexico.

A. F. CRANK, of the Blaisdell Co, of Los Angeles, Cal., has gone to South Africa to manage the H. W. Blaisdell Co., Ltd, of London, Eng., which has the foreign agency for the construction of the H. W. Blaisdell cyanide vat excavating machinery. A. A. Talmage of Los Angeles will take Mr. Crank's place as manager of the American branch of the company, with headquarters at Los Angeles, Cal.

Catalogues Received.

Standard size (6x9) is the Standard Diamond Drill Co.'s 1903 catalogue, replete with interesting points regarding diamond prospecting core drills, giving a historical account of the business, descriptions of drills for surface or underground work, with details as to sizes and prices, illustrated specific description of diamond drill boring tools and supplementary chapters on "How to Select a Diamond Drill Outfit," "Instructions for Operating Diamond Drills," "Instructions for Setting Diamond Bits," etc. The catalogue is finely issued by the Standard Diamond Drill Co., 1644 Monadnock Blk., Chicago, U. S. A., and, like all similar trade treatises noticed herein, will be sent to any address on request.

"Excavation of Rock by Machinery" is the title of Catalogue No. 51, 1903, from the Sullivan Machinery Co., whose general office is at 135 Adams St., Chicago. It is copyrighted, and its technical contents are worth copyrighting for the information contained therein and its sumptuous illustrations. The rock drill is a great thing in modern mining, and this latest brochure from the Sullivan Machinery Co. is a notable addition to the sum total of knowledge thereon. To any one interested in drills the book is commended as worth early consideration. The fact that it is of standard size (6x9 inches) makes it convenient for filing and permanent preservation, and the high grade of its publication entitles it to a place in one's library. Viewed mechanically, it is a work of art, and is a good exemplification of the truism that "the best is none too good"—for those who want to know about the Sullivan Machinery Co. The illustrations on page 94 of the Sullivan patented flexible joint are splendid specimens of fine portraiture, as are many others scattered through the handsome book, which will be sent to any designated address.

Obituary.

MATTHEW BROWN, mechanical engineer for the South Geldenhuis Deep, Ltd., at Germiston, South Africa, died July 5th from heart disease, after an illness of one week. Deceased was a native of Glasgow, Scotland, and at one time was located in San Francisco, Cal. He is survived by a widow.

Commercial Paragraphs.

THE Redfield Drill Co., 1606 Blake St., Denver, Colo., reports the sale of its hand drills to the following parties: Rand Development Co.; Oroville, Cal.; Buckeye G. M. M. & T. Co., Idaho Springs, Colo.; Turk M. Co., Deertrail, Wash. The Utah agents, the Salt Lake Hardware Co., also report the sale of one.

THE Lagonda Mfg. Co. of Springfield, Ohio, is in receipt of the following letter: "Gentlemen: We used your Weinland No. 8 water-power cloaner to clean a battery of four Babcock & Wilcox boilers, with the result that we are now saving 20% on our fuel. We consider it a great machine. Yours truly, (Signed.) O. E. Randolph, Gen. Supt. Union Waxed & Parchment Paper Co., Franklin, Ohio."

New Patents.

DEWEY, STRONG & CO.'S SCIENTIFIC PRESS PATENT AGENCY, 330 Market St., S. F., has official reports of the following U. S. patents issued to Pacific coast inventors:

FOR WEEK ENDING AUGUST 4, 1903.

735,439.—BOTTLE—N. D. Asdell, Lakeview, Or.
735,462.—KILN—W. A. Butler, S. F.
735,207.—GAGE SQUARE—J. Campbell, Cascade, Or.
735,223.—RAIL JOINT—W. S. Dunagan, Everett, Wash.
735,234.—QUARTZ MILL—J. F. Forward, San Diego, Cal.
735,081.—CHECKBOOK—J. Franc, Pasadena, Cal.
735,497.—RANGE FINDER—G. Griffith, S. F.
735,248.—PUMP PISTON—J. Hahn, Los Angeles, Cal.
735,501.—EXTRACTING GOLD—Harp & Starkweather, Stockton, Cal.
735,374.—STAMP MILL MORTAR—J. H. Hendy, S. F.
735,512.—TREATMENT OF ORES—H. Hirschling, S. F.
735,257.—SCRAPER—J. R. Hodgins, Taeoma, Wash.
735,516.—HANDLE—J. M. Horton, Crescent City, Cal.
735,518.—MECHANICAL MOVEMENT—J. H. Hussey, Spokane, Wash.
735,388.—SWINGING SCRAPER—D. B James, S. F.
735,106.—SUCTION PIPE—J. Jorgensen, Seattle, Wash.
735,268.—ADZ—O. Keehme, B shee, Ariz
735 531.—ELECTRIC SWITCH—O. M. Lacey, Hanford, Cal.
735,545.—FLOATING FISH TRAP—L. Mahew, Whatcom, Wash
735,564.—CONVEYER—W. L. McCabe, Seattle, Wash.
735 280.—SPICE BOX TOP—E. B. Millar, Los Angeles, Cal.
735,576.—RAILWAY SWITCH—J. M. Payne, Spokane Wash
735,578.—CANDLESTICK—Peterson & Fielding, Grants Pass, Or.
735,146.—THRESHER—T. Powell, Newhope, Cal.
735,590.—STAMP MILL—G. C. Richards, Berkeley, Cal.
735,600.—COUCH FRAME—A. Shrock, S. F.
735,595.—LOCATING SHIPWRECK—R. Sato, S. F.
735,691.—FISH NET LIFTER—A. F. Sbadel, Lopez, Wash.
735,606.—SEWING MACHINE—D. M. Smyth, Pasadena, Cal.
735,321.—WATER HEATER—F. Walker, Los Angeles, Cal.
735,182.—ELECTRIC HEATER—D. M. Watson, Portland, Or.
735,323.—DIVING APPARATUS—J. L. Watson, Los Angeles, Cal.
735,638.—MOTOR BICYCLE—O. E. Waxel, Oakland, Cal.
735,636.—BRAKE BLOCK—O. Whitmore, San Diego, Cal.
735 638.—PACKACING LIQUIDS—G. O. Wickson, S. F.
735,642.—BOTTLE—P J. Wilson, Ben Lomond, Cal.

Notice of Recent Patents.

Among the patents recently obtained through Dewey, Strong & Co.'s SCIENTIFIC PRESS U. S. and Foreign Patent Agency, the following are worthy of special mention:

SWITCHES FOR SYSTEMS OF REMOTE CONTROL.—No. 735,531. Aug. 4, 1903. O. M. Lacey, Hanford, Cal. This invention relates to improvements in electric switches by which lamps, motors and the like may be conveniently controlled from a point remote from the installation. Its object is to provide a device of few parts and one which is economical in manufacture and simple and positive in operation. One advantage of this switch is that a single operating wire is sufficient where two are usually employed, the opening and closing being done by this one wire, which has its suitable return connection with a source of energy.

STAMP MILL.—No. 735,590. Aug. 4, 1903. G. C. Richards, Berkeley, Cal. This invention consists in a mechanism for actuating the stamp, a means for adjusting the stamp stem and shoe, means for regulating the position of the actuating lever to vary the drop of the stamp and adjusting each stamp and stem independently, and means for raising the stamp stems for the purpose of replacing the shoes when old and worn out.

STAMP MILL MORTAR.—No. 735,374. Aug. 4, 1903. J. H. Hendy, San Francisco, Cal. This invention consists of single independent sectional mortars for each individual stamp, said mortars being arranged side by side upon a sole-plate singly or common to a series of mortars and stamps. Mortars have commonly been made in a single piece and are very heavy; the object of this invention is to so construct the mortars that they may be taken to pieces and reduced to the smallest possible weight, so that they can be transported by pack animals.

DETACHABLE COLLAPSIBLE COUCH FRAME.—No. 735 600. Aug. 4, 1903. Amos Schrock, San Francisco, Cal. Sofas, couches, etc., are usually made with wooden frames or bases, so joined together that there can be little reduction in size for shipping purposes. The object of this invention is to provide a couch with a separable iron frame and means by which the frame can be folded into a small compass when desired.

Latest Market Reports.

SAN FRANCISCO, August 14, 1903.

METALS.

SILVER.—Per oz., Troy: London, 25 9/16d (standard ounce, 925 fine); New York, bar silver, 54¾c, refined (1000 fine); San Francisco, 54¾c; Mexican dollars, 42c San Francisco, 42c New York.

COPPER.—New York: Standard, $13.12½; Lake, 1 to 3 casks, $13.00@13 12½; Electrolytic, 1 to 3 casks, $13.62½@13.75; Casting, 1 to 3 casks, $12.75; San Francisco: $13.00. Mill copper plates, $17.00; bars, 18@24c. London: £58 5s spot per ton.

Calumet & Hecla Co. is evidently endeavoring to raise the price of copper or has none for sale at present prices.

It is reported that the Calumet & Hecla is offering no copper under 13¾c Having recently sold a large amount of copper for future delivery at 13c or a little better, is now apparently out of the market.

European consumers have followed the policy of buying from hand to mouth, and are said to be running on short supplies. Copper in England and France for the first half of 1903 is returned at 51,102 tons, against 70,969 tons for same period in 1902, and 54,818 tons for the first six months of 1901. The official German returns for the first months of this year show a consumption of foreign copper (pyrites excluded) of 31,848 tons against 30,223 tons in the same months of 1902 and 23,561 tons in 1901. A distinct improvement is thus evident in Germany.

LEAD.—New York, $4.20; Salt Lake City, $3.50; St. Louis, $4.00; San Francisco $4.50, carload lots; 4¾c 1000 to 4000 lbs.; pipe 5½, sheet 6, bar 5½c; pig, $4.75. London: £11 1s 6d per long ton=2.75c per lb.

SPELTER.—New York, $5.87½; St. Louis, $4.85; London, £20 5s per ton; San Francisco, ton lots, 6¼c; 100-lb lots, 7c.

ANTIMONY.—New York, Cookson's, 9¾c; Hallett's, 8½c; San Francisco, 1000-lb. lots, 7½c; 300 to 500 lbs., 7½c; 100-lb. lots, 10c.

TIN.—New York, pig, $28.25@28.70; San Francisco, ton lots, 28½c; 500 lbs., 29c; 200 lbs., 29½c; less, 30c; bar tin, ℔ lb, 30c @32½c. London, £128 5s spot.

PLATINUM.—San Francisco, orude, $18.00 ℔ oz.; New York, ingot, $19.00 per Troy oz. Platinum ware, 75@80c per gram.

QUICKSILVER.—New York, $44.50@46.00; large lots; London, £8 15s; San Francisco, local, $44.50 ℔ flask of 76½ lbs.; Denver, $49.50. Export, $43.50.

BABBITT METAL.—San Francisco, No. 1, 10c; No. 2, 7c; No. 3, 6½c; extra, 17½c; genuine, 35c; Eclipse, 37½c.

ALUMINUM.—New York, No. 1, 99% pure ingots, 35c; No. 2, 90%, 30c to 34c.

SOLDER.—Half-and-half, 100-lb. lots, 18.75c; San Francisco, Plumbers', 100-lb. lots, 15 50c.

NICKEL.—New York, 50@60c ℔ lb.; ton lots, 45@48c.

STRUCTURAL MATERIALS.

IRON.—Pittsburg, Bessemer pig, $18.85 @19.00; gray forge, $17.10; San Francisco, bar, 3c ℔ lb., 3½c in small quantities.

STEEL.—Bessemer billets, Pittsburg, $27 00@29.00; open hearth billets, $28.00; San Francisco, bar, 7c to 12c per lb.

LUMBER.—(Retail): Pine, ordinary sizes, $20.00@22.00; extra sizes higher; redwood, $22.00@23.00; lath, 4 feet, $4.25 @4.50; pickets, $19.50; shingles, $2.35 for No. 1 and $2.00 for No. 2; shakes, $13.50 for split and $14.50 for sawed; rustic, $26.00 @32.00.

NAILS.—Per keg (list prices): No. 20d to 60d, Wire, $3.25; Cut, $3.35; 10d to 16d, Wire, $3.35; Cut, $3.35; 8d, Wire, $3.40; Cut, $3.40; 6d and 7d, Wire, $3.50; Cut, $3.50; 4d and 5d, Wire, $3.60; Cut, $3.60; 3d, Wire, $3.75; Cut, $3.75; 2d, Wire, $4.00; Cut, $4.00. Special rates for carload lots.

LIME.—Santa Cruz, $2.25; Roche Harbor, $2.25 per bbl.

CEMENT.—Germania, $2.50 @ 2.75; Hewmoor, $2.90; Trowell, $2.90; Portland, $2.50@2.75 per bbl.

GENERAL SUPPLIES.

POWDER.—F. o. b. San Francisco: No 1. 70% nitro-glycerine, per lb., in carload lots, 15½c; less than one ton, 17½c. No. 1*, 60%, carload lots, 13½c; less than one ton, 15½c. No. 1** 50%, carload lots, 11½c; less than one ton, 13½c. No. 2, 40%, carload lots, 10c; less than one ton, 12c. No. 2, 35%, carload lots, 9½c; less than one ton, 11½c. No. 2** 30% carload lots, 9c; less than one ton, 11c. Black blasting powder in carload lots, minimum car 728 kegs, $1.50 per keg; less car lots, $2 per keg.

CAPS.—3x, $5.50 per 1000; 4x, $6.50; 5x, $8; Lion, $9, in lots not less than 1000.

FUSE.—Triple tape, $3.60 per 1000 feet; double tape, $3.00; single tape, $2.65; Hemp, $2.10; Cement No. 2, $3.00; Cement No. 1, $2.65, in lots of 3000 feet and up.

CANDLES.—Granite 6s, 16 oz., 40s., 10½c ℔ set; 14 oz., 40s., 9½c.

CHEMICALS.—Cyanide of potassium, 98%–99%, jobbing, 24@25c ℔ lb.: carloads, 23@24½c; in tins, 35c; soda ash, $2.00 ℔ 100 lbs.; hyposulphite of soda, 2½@3½c ℔ lb.; caustic soda, in drums, 3@3½c ℔ lb; Cal. s. soda, bbls., $1.25@1.50 ℔ 100 lbs.; sks., $1.05; chlorate of potash, 12@13c; nitrate of potash, bbls., 10c; caustic potash, 10c in 40-lb tins; borax concentrated, 7@8c ℔ lb.; roll sulphur, 4@6c; powdered sulphur, 2@3c; flour sulphur, Fronch, 2@3c; alum, $2.00@2.25; California refined, 2@2½c; sulphide of iron, 9c ℔ lb.; copper sulphate, 5@7c; chloride of lime, spot, $2.50@2.75; sulphuric acid, in carboys, 66% B, 2½c ℔ lb.; nitric acid, in carboys, 8c ℔ lb.

OILS.—Linseed, boiled, bbl., 44c; cs., 49c; raw, bbl., 42c; cs., 47c; Lucol oil, boiled, bbl., 41c; cs, 49c; raw, bbl., 39c; cs, 49c. Kerosene—Pearl, per gal., 20½c; Astral, 20½c; Star, 20½c; Extra Star, 24½c; Eocene, 23½c; Elaine, 26½c; Water White, in bulk, 14½c; Mineral Seal, iron bbls., 18½c; wooden bbls., 21c; cs, 24c; Mineral Sperm, cs, 26½c; Deodorized Stove Gasoline, bulk, 17c; do., cs., 23½c; 86° Gasoline, bulk, 21c; do., cs., 27½c; 63° Naphtha or Benzine, deodorized, in bulk, per gal., 16c; do., in cs., 22½ c; Lard Oil, E. W. S., bbl., $1.00; cs., $1.05; Neats-foot Oil, pure, bbl., 75c; cs., 80c; Sperm, crude, 70@60c; Natural White, 65c; Bleached do, 50c; Whale Oil, cs, 50@55c.

COAL.—San Francisco, coast, yard prices: Wellington, $8.00; Seattle, $6.50; Coos Bay, $5.50; Southfield, $8.00. Cargo lots, Eastern and foreign: Wallsend, $6 .50 Brymbo, $7.50; Pennsylvania, bd., $14. 00 Scotch, $8; Cumberland, $12; Cannel, $9.00; Welsh Anthracite, $11.50; Rock Springs, $9.50, long ton; Colorado Anthracite, $14.00. Coke, $10.50 per ton in bulk, $13 in sacks; Sunnyside, $8.50, long ton.

WHITE LEAD.—Per lb., in kegs: 500 lbs. and over at one purchase, per lb., 6c; less than 500 lbs., per lb., 6½c; in 25-lb. tin pails, ½c per lb. above keg price; in 1 and 5 lb. tin cans, 100 lbs. per case, ½c per lb. above keg price. Dry Lead—In bbls., 1 ton and over, 6c; do. in kegs, 6½c.

RED LEAD.—500 lbs. and over at one purchase, per lb., 6c; less than 500 lbs., 6½c.

LITHARGE.—Pure, in 25-lb. bags, 8 @9c per lb.

BONE ASH.—Extra No. 1, 5@6c per lb. No. 1, 4@5c.

BORAX.—Concentrated, 7@9c per lb powdered, 9@12c; fused, 25@30c.

BORAX.—Crystal, 7c; calcined, 25c.

MANGANESE.—Pure, ℔ lb., 60c.

SODIUM.—Metal, ℔ lb., $1.00.

MOLYBDENUM.—$2 per lb.

MERCURY.—Bichloride, ℔ lb., 90c.

PHOSPHORUS.—(American) ℔ lb., 75c.

SILVER.—Chloride, ℔ oz., 90c@$1.00; nitrate, 55c.

ALUMINUM.—No. 1, 99%, small lots, 37c ℔ lb.; 100 lbs., 35c; 1000 lbs., 34c; ton lots and over, 33c, Pittsburg. No. 2, 90%, small lots, 34c; ton lots and over, 31c, Pittsburg.

URANIUM.—Oxide, ℔ lb., $3.50.

ZINC.—Metallic, chemically pure, ℔ lb., 50c; dust, ℔ lb., 10c; sulphate, ℔ lb., .04c.

(These prices are wholesale, f. o. b. San Francisco, unless otherwise noted.)

Valuable Books for Prospectors and Miners

Orton.—Underground Treasures: How and Where to Find Them. A Key for the Ready Determination of all the Useful Minerals within the United States. By Jamee Orton, A. M., late Professor of Natural History in Vassar College, N. Y., etc. A New Edition with an Appendix on Ore Depoelte and Testing Minerals with the Blow-Pipe. Illuetrated. Price.....$1.50

Osborn.—The Prospector's Field Bo k and Guide in the Search for and Easy Determination of Ores and other Useful Minerals. By Prof. H. S. Oeborn, LL.D. Author of "A Practical Manual of Minerals, Mines and Mining." Illustrated by 58 engravings. Fifth edition, revised and enlarged. 315 pages, 12mo. Price.....$1.50

Osborn.—A Practical Manual of Minera's, Mines and Mining: Comprising Suggeetione ae to Localitiee and the Aesociatione of all the Useful Minerals. Full deecription e of the Most Effective Methode of Both the Qualitative and Quantitative Analyeee of Each of theee Minerals and Hinte upon the Various Operatione of Mining, including Architecture and Construction. By Prof. H. S. Oshorn, LL.D. Illustrated by 171 engravings. Second edition, revieed and en'arged. 393 pages, 8vo. Price.....$4.50

Lieber.—The Assayer's Guide: or, Practical Directione to Aesayere, Miners and Smeltere, for Teete and Aseaye, by Heat and by Wet Proceee es of the Ores of all the Principal Metals, of Gold and Silver Coine and Alloye, and of Coal, etc. By Oscar M. Lieber. A new, revieed and enlarged edition. Illustrated. 283 pagee 12mo. Price.....$1.50

Erni and Brown.—Mineralogy Simplified: Easy Methode of Identifying Minerals including Oree, by Means of the Blow-Pipe, by Flame Reactione, by Humid Chemical Analysis, etc. A New and Revieed Edition, 411 pagee, illuetrated by 96 engravings. Pocket-book form, morocco gilt edges. Price.....$2.50

Duncan.—The Practical Surveyor's Guide: Containing the necessary information to make any pereon of common capacity a finished land eurveyor, without the aid of a teacher. By Andrew Duncan, Land Surveyor and Civil Engineer. A new, revieed and greatly enlarged edition. Illuetrated by 72 engravinge, 214 pagee, 12mo. Price.....$1.50

MACHINERY FOR SALE.

EXCEPTIONAL BARGAIN!

ONE FOUR-FOOT FRUE VANNER, fitted with Brownell Patent Lip Flange Belt. Vanner and Belt abeolutely new. Address Fricot & Miller, Latrobe, El Dorado Co., Cal.

SECOND-HAND

Dynamos, Motors, and Electrical Appliances.
All Money Savers.
Repair Anything.

Have You a Dynamo or Motor For Sale?

GUARANTEE ELECTRIC COMPANY,
8 W. Cor. Adams and Clinton Sts., Chicago.

A COMPLETE CONCENTRATING PLANT

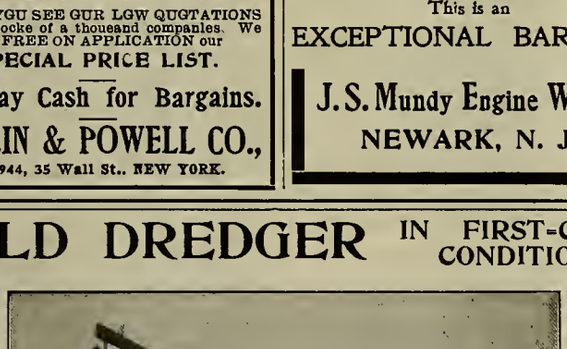
Can be bought at 12c. on the $1. The machinery is of the highest type and in good condition.

One 200 h. p. Corliss Type Engine. Two Safety Tube Babcock & Wilcox Boilers, about 250 h. p. One 800-lb. High Mortar 40-etamp Mill, rapid drop. One 9x15 in. Blake Crusher. Eight Tullock Automatic Ore Feeders. Twelve Double-end 3-Compartment Hartz Jigs. One 4-Compartment Single Hartz Jig. Six Sets Revolving Screens, all housed in. Two Sets of Elevators, complete. All necessary Shafting, Pulleys, Boxes, Belting and most of the piping, etc. This plant has been used very little. It cost $100,000; if sold at once, will take $12,000 for it. Located on the D. & R. G. Ry.

S. S. MACHINERY COMPANY,
1539 Lawrence St. Denver, Colo.

HOISTING ENGINE AT HALF PRICE

Abeolutely new, in perfect condition, made on order but found to be not ae well euited to the peculiar conditione exieting at that mine as one of our other typee, which we built and shipped in ite place. Thie engine, which we offer at 50% of its first coet, ie one of our etandard double friction drum, link-reversing motion engines, with brake bands, 130 h. p., 14x24 cylinders and 64-inch drums. Dozens of thie type are in mining use. If desired, we will make changee in this engine to meet special needs. Write at once for illustration and full detaile, etating your requirements, or



Wire at Our Expense.

This is an

EXCEPTIONAL BARGAIN.

J. S. Mundy Engine Works
NEWARK, N. J.

GOLD DREDGER IN FIRST-CLASS CONDITION.

Now operating upon leaeed ground, Alder Gulch, Montana. To be sold or removed upon expira ion of lease. If you are INTERESTED IN DREDGING GROUND, inspect plant in operation or write for description and particulars. Only one mile from railroad.

CHICAGO MINING & DEVELOPMENT CO., Ruby, Madison County, Montana.

[ELATERITE IS MINERAL RUBBER.]

YOU MAY INTEND BUILDING
or find it necessary to REPLACE A WORN-OUT ROOF.

ELATERITE ROOFING

Takes the place of shingles, tin, iron, tar and gravel, and all prepared roofings. For flat and steep surfaces, gutters, valleys, etc. Easy to lay. Tempered for all climates. Reasonable in cost. Sold on merit. Guaranteed. It will pay to ask for prices and information.

THE ELATERITE ROOFING CO.,
713 Market Street, San Francisco.

OUR BARGAIN COLUMN.

WIRE HOISTING ROPE

Four carloads of eecond hand wire holeting rope put up on reels; in first-class condition. Sizee 1, 1¼, 1⅜ and 1½-inch. Write for pricee.

PIPE.

Gor etock of good standard black eecond hand pipe, with gnaranteed threade and couplinge, as follows:

100,000 feet	1	inch, per foot	$ 03¼
200,000 "	1¼	" " "	04¼
50,000 "	2	" " "	07¾
200,000 "	2½	" " "	10
50,000 feet	1	inch EXTRA HEAVY, per foot	$ 04
55,000 "	1¼	" " " "	05½

800 feet	8	inch, with flangee, per foot	$ 70

Variations in Construction.

Each mine superintendent has his own ideas about construction details of head-frames and other structures, and although these ideas, as represented in the various types of frames seen at shafts throughout the mining regions often vary considerably from the ideas of those of mechanical engineers, these frames generally answer fully all requirements. In some instances the frames are built with reference to the material available for their construction. In other cases, they are framed for strength, and are capable of sustaining twenty or even fifty times the load ever put upon them. In such instances the trained engineer would economize material and labor. It is no uncommon thing to see a massive head-frame of 12x12 timbers with a ⅝-inch rope over the sheave wheel. A two-post wheel is the most economical for capacity and general utility that can be built. The accompanying illustrations are of two frames in widely separated mining districts, one in Mexico, the other in Oregon. The latter, which is at the Gold Pan mine near Sumpter, Or., presents a most unusual arrangement at the top of the frame, and while no explanation is offered by the manager of the mine, it has the appearance of being an alteration from an original plan. By letting a tie into the main posts and setting two short upright posts between the cap and tie, between which the sheave could have been placed supported on post boxes, the "back framing" could have been dispensed with. This would throw the sheave forward, probably too far, but if this be the case it should have been anticipated and the main posts set back accordingly. The entire structure presents an interesting study in head-frame construction and the jointing appears to be all that could be desired. The bucket is dumped at the side into a chute, into which the waste or ore is delivered into a car. A "jack head" pump has been installed, run by belt from the engine within the hoist building.

In comparison, the frame illustrated in the smaller picture, one of those at Cananea, Mexico, shows the latter built from the surface of the ground, whereas the Oregon frame is supported on a superstructure of posts and sills. Apparently at the Mexican shaft the ore is dumped directly from the skip or bucket into the car, though the illustration does not show clearly how this is accomplished. This frame is provided with side braces to reduce vibration and secure safety, and the Oregon frame is supplied with guy wires for a similar purpose. All of the several types of construction shown herein from time to time are interesting and instructive to miners throughout the mining regions everywhere.

Head Frame at Gold Pan Mine, Near Sumpter, Oregon.

Specimen Stealing.

One of the perplexing problems of the Western Australia mine manager is that of preventing the theft of ore rich in gold from the telluride mines of the district. It is said hundreds of thousands of dollars have been stolen by miners within the past few years. This has been taken in the form of specimen ore from the various mines and sold by those taking the same to others who, it seems, have made a profitable business of this illicit gold buying.

Some of these dealers, it is said, have shipped regularly from $2000 to $5000 monthly in gold bars, which could only have come into their possession in the dishonest manner indicated. One curious phase of the affair is that at various times several companies have received through the mails and otherwise sums aggregating thousands of dollars, accompanied by anonymous letters, stating that the money was obtained by the sale of stolen gold specimens—conscience money, in fact—and the companies argue very reasonably, that if this large amount of money is voluntarily returned by those whose conscience pricks them for acts of dishonesty, there is a reasonable probability that a very much larger amount is still retained by others, whose conscience is less sensitive. It is proposed to organize an association similar to that existing in the South African diamond fields, to apprehend the diamond thieves and illicit diamond buyers, who are familiarly known as the "I. D. B.'s." Every mining district where very valuable ore or gems are produced has the same experience. In America about the only attemp, made to check this sort of thing is a careful searching of the men at the mine change houses, but this is not always effective.

THE cheap labor problem continues to be the one feature of interest in the mines of the Rand, South Africa. The latest reports show that the "receipts" of natives are slightly greater than the discharges and desertions. The mines have agents seeking natives throughout Africa who will voluntarily go to work in the mines; but there is objection to this in the countries from which it had been hoped to renew the supply. While there are many mine managers who are willing to employ Chinese, there is a popular sentiment against it. Not only the mines but the farms are short of the necessary laborers. From among the teeming millions reported to inhabit central Africa there should be no difficulty in recruiting sufficient laborers, but such seems not to be the case.

Labor Troubles Retarding Investment.

One of the most serious phases of the long continued labor disturbances is the effect it is having on capital usually available for mining investment. From various Eastern, as well as Western cities, comes the same expression of fear to invest in mining enterprises in either the United States or British Columbia. It has been clearly and repeatedly demonstrated that the development of the industry is being retarded by these frequent clashes between owner and operator and the Western Federation of Miners. Capital does not feel secure under such conditions and is withheld until the storm is past. Men of means are not accustomed to having their employes run their business entirely, preferring to have something to say in the matter themselves. The position taken by the unions — that of placing all men engaged in any particular branch on a parity has never been successful, and can never be so for any considerable length of time, as it is contrary, not only to custom, but to the dictates of common sense. All men may be created equal, but they do not long remain on this common plane. Some are sure to advance more rapidly and become superior to others, and this is true in every walk in life.

Investors ask, "is there anything good in Mexco?" A review of the mining situation the past few months shows that an enormous amount of capital has been diverted from investment in mining enterprises in the United States to Mexico, and the reason for it can be found in the repeated and long-continued troubles between labor and capital here. Gold mining is unlike any other business. The manufacturer may be obliged to submit to the dictation of his workmen, but not so the gold miner, and when the unions become too unreasonable in their demands, the mine owner simply closes his mine, locking up the gold in the unworked stopes of the mine, and quietly waits.

The principal feature of the week, or at least that which attracts most attention from miners of the West, is the renewal of trouble between the Western Federation of Miners and the mine and mill owners and United States Reduction and Refining Co. in Colorado. The difficulty was resumed at Colorado City two weeks ago and has been carried again into the Cripple Creek district, where there are now about 4000 miners, and other workers dependent upon the operation of the mines, out of employment.

For months past a state of unrest has existed throughout the mining regions of the West. Strikes have been numerous, but in most cases the differences have been adjusted, temporarily at least, and work has proceeded as before. In some instances the miners were successful, in others they lost, and scattered throughout the West. One of the managers of the Western Federation, having been worsted in his efforts in Arizona, hastened to California, where at Jamestown, Quartz and Stent, in Tuolumne county, he is said to have advised the men who are on strike there, who were single, to go at once to Clifton and Morenci, where they could take the place of the strikers who were refused employment, thus giving the resident miners in Tuolumne county "a chance to win." This is a single example of the manner in which these strikes are engineered.

In Amador county, California, the scene of a recent strike which ended to the advantage of the union, there is now trouble between the miners and the engineers, carpenters, and other topmen, who have organized themselves into a separate organization, and it is reported a strike is daily expected there in consequence.

In southern Nevada and southern California the strike, in which the principal mines of that region are involved, continues. Where there were about 400 miners in Randsburg district, there are now about twenty. At Searchlight, Nevada, a similar condition prevails. The mine operators who are organized there remain firm in their announced determination to keep the mines closed until they can operate them without interference from the organized miners.

In British Columbia the coal miners' strike on Vancouver island was lost. The threat of the owner, Dunsmuir, to put Chinese in the mines, together with the fact that the Western Federation did not supply the promised financial aid to the men who were out, resulted in the miners renouncing the Western Federation and returning to work, having gained nothing. On Texada island, above Vancouver, the miners of the Marble Bay Co. of Tacoma, Wash., associated themselves with the Western Federation, and demanded eight hours for miners and nine hours for topmen, at the same wages as was previously paid for ten hours. The owners refused to entertain the proposition and promptly closed the mines, which had been shipping steadily for the past three years.

In the case of the Cripple Creek strike, opinion is divided, as usual, but the consensus of opinion is that the miners had no grievance, and that the strike is purely of a sympathetic nature, intended to assist the striking mill and smelter men to win at Colorado City. The mine owners and reduction works managers are organized, and declare that the conditions under which the industry has been carried on the past year must terminate one way or another, and they have determined to shut down and continue closed until the miners come to their senses. In most of the largest mines of Cripple Creek district the union wages are paid, eight hours constitute a day's work, and all conditions demanded by the Western Federation have been practically complied with, excepting that some men are employed who are not members of the Federation, and that the Western Federation or its representatives are not officially recognized. The merchants and other business men are not generally in sympathy with the methods of the Federation, and have inaugurated a cash system in the stores, which means that the merchants do not intend to carry the strikers, and that the miners will be forced to receive financial support from the Federation or stand the expense of the strike individually, which a large percentage of them are unable to do. The miners of Cripple Creek are losing time, or money, at the rate of about $12,000 a day. The mine owners sustain a nominal loss, but the gold still remains in the veins, to be recovered at some subsequent time, when conditions are more favorable than at present. Merchants, railroads, and others with capital invested in the region must incidentally sustain more or less loss, though in no manner a party to either side of the dispute.

The Cripple Creek drainage tunnel is one of the most important undertakings in the district at the present time, and the mine owners are anxious to have this completed, in order that the mines underneath which it passes may be drained during the present trouble, there remaining but 90 feet unfinished when the strike began. Late dispatches announce that fifty miners have gone to work in the El Paso mine under armed guard. The drainage tunnel is being partly driven from the bottom of the El Paso shaft, and a portion of the men now at work there will advance the headings with all possible speed. It is stated that this attempt to operate under an armed guard is intended as a test of strength, and, if no interference results, other mines will follow the example of the El Paso Company.

That in the majority of cases the miners are being misled there seems little doubt. When the mines pay the wages and hours demanded, and otherwise comply with the wishes of the Federation, and the only excuse for a strike is the fact that mine managers refuse to recognize the Federation officially and deny the agents of the union permission to openly go into the mines and proselyte for membership, there is something radically wrong. Evidently this struggle will be "to a finish." It means complete victory for the Western Federation of Miners in the Cripple Creek region or their disorganization there and in many other places. Whichever way the tide of this battle may turn, it will doubtless have a direct and powerful influence on the labor situation throughout the mines of the West.

CONCENTRATES.

THE rubber sheets, known as sheet packing, may be more easily cut if the knife be dipped frequently in water during the process.

CARBONATE OF SODA will neutralize the acid water so hurtful to the boiler. It may be added in the proportion of one grain per gallon for each degree of acidity in the water.

THE Chilian mill is employed where it is necessary to grind ore very fine. The capacity varies with the size of the mill, weight of grinding wheels, power applied and screen used.

AT THE Broken Hill Proprietary mine, Broken Hill, New South Wales, 58,320 cubic yards of waste were broken in the open cuts for filling in underground stopes during the half year ending May 31, 1903.

CAREFUL experiments in sizing pulp from mill batteries before sending it to concentrating machines indicates that by proper arrangements in this direction in many instances canvas slimes plants may he dispensed with.

IN some canvas plants the grade is fixed at three-fourths of an inch to the foot, but experience has shown that to accomplish the most satisfactory results the grade should be adjustable, though few tables are so arranged.

TALC of good variety is worth in the Eastern markets at the place of production from $6 to $8 per ton. It is used largely in the manufacture of some kinds of paper, and in ornamenting wall paper, and also in the manufacture of tips for gas and acetylene burners.

THE greatest depth from which ore is being hoisted on the Rand, South Africa, is about 2500 feet, but there are deeper shafts than this which are sinking to reach the banket. Some of the latter approximate 4000 feet in vertical depth.

THE usual grade of a placer sluice box is 8 inches to the 12-foot box. If the gold be very fine a lighter grade may do better, though a longer line of sluices may be necessary. Twenty inches, or 30 cubic feet of water per minute, is usually considered a "sluice head" in placer mining.

THE limit of successful electrical power transmission does not seem to have been reached, and it would be difficult to even approximately indicate what that limit might be. In California, as a commercially profitable business proposition, 40,000 volts are transmitted over 200 miles.

THE San Roque placers are in Lower California, and were discovered in the summer of 1900. A large number of men stampeded to that section only to be disappointed—as usual the mines were not profitable—though gold actually did exist in small quantities in the alluvial of the district.

OCCASIONALLY gold ores are met with which are not "free" and which contain no sulphurets. Such ores usually contain also chloride of silver in addition to the gold. Some ores of this character after treatment with byposulphite of soda will yield a large percentage of gold by amalgamation.

THE rock specimen from Ibapah, Utah, is quartz with yellow scales of wulfenite (lead molybdate), and the green crystals are pyromorphite, a composition of lead, chlorine and phosphorous pentoxide. The phosphorous is sometimes replaced by arsenic, and with increasing arsenic it passes over to minette.

THE angle of inclination of a working shaft should not be changed if it is possible to avoid it. Hoisting can be more speedily and economically accomplished through a straight shaft than through one sunk at a variable angle. On no account should the alignment be changed, no matter what changes may be made in the angle of dip.

THE Western Federation of Miners originated in Montana in 1878. It has since extended its influence into every mining State of the West and into almost every camp, including British Columbia, and recently an attempt was made to carry the work of organization into Mexico, but as far as learned without marked success thus far.

THE number of holes to be drilled in a shaft to constitute what is known as a "round" must be determined by the size of the shaft and character of the rock. The proper depth of each hole must be judged by the miner himself or by the foreman. The direction of the holes is determined by the pitch of the formation and jointing planes.

ORDINARILY there is some loss and error in a fire assay. Such loss is an indeterminate quantity. With a gold ore going one-half ounce to the ton the loss will sometimes run as high as 3% to 5%; with an ore going one ounce to the ton the loss may vary from 2% to 3%; with a four-ounce ore, 1% to 2%. A one-ounce silver ore may lose 10% to 12% during an assay; a ten-ounce ore, 6% to 7%; a 100-ounce ore, 4% to 5%.

THE rock specimens from Terrazas, Mexico, are pitchstone porphyry, also known as vitrophyre. It is a variety of volcanic glass and commercially worthless. Pitchblende is a different mineral, having a sub-metallic to dull lustre; is grayish, greenish, brownish to velvet black. Not so hard as the pitchstone, which readily scratches glass.

THE cost of treating sulphides in California, as at other places, varies with the character of treatment, and to some extent with the value of the ore, particularly when the concentrates are shipped. The costs are: Concentrating and delivery to drying floor; sacking; cost and wear and tear of sacks; transportation, usually both by wagon and rail; treatment charges and discounts of smelter or mill treating the ore.

THE use of gold amalgam instead of quicksilver alone in pan amalgamation has proven very beneficial in working some gold ores by pan amalgamation, particularly if the ore be ground in arrastras instead of iron pans. It appears, according to Stetefeldt, who experimented along these lines in Mexico, that contact of iron during pan amalgamation is detrimental, though no satisfactory reason has been assigned for this.

THE roasting of ores as preliminary to chlorination has for its object the expulsion by burning or volatilization of the sulphur, arsenic, antimony and other volatile substances in the ore. This is usually accomplished in a reverberatory furnace. Wood or oil is usually employed as fuel—the latter is the better, as the flame can be regulated with more exactness and the sulphides can be completely roasted in less time than by the use of wood. The ordinary hand reverberatory (single hearth) has a capacity of 2½ to 5 tons in twenty-four hours, dependent somewhat upon the size of furnace, character of ore and kind of fuel used. The cost per ton ranks with size of furnace, cost and kind of fuel and cost of labor.

THE impact water wheels of high efficiency which are in use to-day are the outcome of long years of experiment. The original impact iron wheel was known as the "hurdy-gurdy." It was an imperfect device, as compared with the improved wheels of the present day, but it had a much higher efficiency than any form of wheel previously introduced. The force of the water exerted on the bucket of an impact wheel depends on the velocity of the water and the form of its path, and also on the extent to which it is deflected from its original course, and on the angles of entrance and exit from the bucket, and not largely on the form of the curve, assuming the latter to be continuous and the curvature not too abrupt.

SILVER PLATES would probably give better satisfaction for the purpose of amalgamating gold ores in stamp mills than silver-plated copper plates, but mill men and mine owners object to the outlay of money necessary to provide the silver plates, and yet silvered copper plates, or even raw copper plates, after a few years use on ore of medium grade become more valuable than the silver plates would be when new, by reason of absorption of gold. Plates have been known to absorb hundreds of dollars in gold, while presenting practically the same appearance as when new. The best amalgamating surface on a plate is a coating of gold amalgam, but most mill men are too anxious to secure a good cleanup to allow the gold to accumulate any more than absolutely necessary.

THE first attempt to extract gold from its ores by use of cyanide of potassium solutions was made in 1867 by J. H. Rae, who took out a patent on his process. This patent also included the use of electricity in the process. In 1880 J. W. Simpson obtained a patent for treating ores containing gold, silver and copper, by employing a solution of cyanide of potassium 3% and ammonium carbonate 0.19%. Copper was to be extracted with the gold. If silver were present sodium chloride was to be added to the solution. This process never came into use, as it was not based on sound reasoning, and the chemical reactions taking place in the solutions by the addition of ammonium carbonate were rather a detriment than an advantage, as it decomposed cyanide rapidly. The gold was precipitated on a plate of zinc.

A LEAKY JOINT on a pipe line under heavy pressure may usually be remedied by placing a broad steel band (4 to 6 inches wide, according to size of pipe) about the joint and drawing it up close with a suitable threaded clamp. The edges of the band should be turned upward slightly before placing on the pipe. When in place narrow strips of lead should be carefully caiked beneath the band entirely around the pipe. This will generally stop the leak, but great care is necessary. The blows of the hammer on the calking tool must be gauged with much care, as after getting the leak practically stopped an unnecessarily heavy blow may undo the careful work of an hour. Every pipe line should be provided with expansion joints to make allowance for expansion due to changes of temperature, and this whether the line be a conduit for water, air or oil.

THERE will always probably be two divisions into which will go those who discuss or study the genesis of ore deposits. In the one division will be found those who busy themselves with the natural phenomena found in the field and the mine; the other will confine their work mostly to the reproduction or analysis of the operations of nature in the laboratory. The former collects isolated facts; the latter assimilates them to later reproduce them in regular and concrete form. To attempt in the limits of a "concentrate" to discuss the genesis of ore deposits would be like an effort to compress the Sierras into a nutshell. Ores or ore deposits may be generally classified as of direct igneous origin, or as deposited by underground water, or the direct result of the process of sedimentation. Circulating underground waters constitute the source of many metalliferous deposits. The subject is a most interesting one and has been exhaustively discussed by many able writers.

IT is probable that the crust of the earth is solid to a depth of about 25 miles. Below that, under a pressure of 10,840 atmospheres and a temperature of 1200° C., the hitherto solid rocks begin to assume the liquid state, while at a depth of 200 miles the heat must be sufficiently great to raise most known substances to their "critical point." (The critical point of a substance is that temperature above which the substance remains gaseous, irrespective of the pressure to which it is subjected.) Below a zone bounded by the highest and lowest critical points of the substances present in that zone the whole interior of the earth must, therefore, be gaseous, but subjected to a pressure so inconceivably great as to become a highly viscous and incompressible mass, so rigid and so incompressible as to behave in all respects like a ball of steel.

THE term "porphyry" is one applied by miners indiscriminately to light colored rocks for which they know no better name. These rocks are usually of igneous origin, though not always so. The word porphyry means purple, and was applied to the purple porphyry of Egypt, a rock from which many monuments and obelisks were made. The term now has a structural significance only and is applied to rocks in which distinct crystals of mineral occur in a finer-grained mass. This ground mass (or back ground, as it might be called) may be coarse or fine, but the porphyritic crystals must be relatively larger. There is quartz-porphyry, feldspar-porphyry, hornblende-porphyry, granite-porphyry, etc., the prefix always indicating the character of the large crystals or phenocrysts. Dark colored basic rocks, with porphyritic structure, are called porphyrite, as diorite-porphyrite, diabase-porphyrite, etc.

THE thickness of a slime cake in a filter press would be determined largely by local conditions, the kind of ore, the fineness of crushing, etc. A 3-inch cake is usually considered none too thick. In treating slimes by filter presses there are two methods in ordinary use. In one the slimes, having been separated from the sands by means of spitzlutten and afterwards settled in V boxes and settling vats, are agitated with weak cyanide solution of requisite strength, and when the solution of the gold is complete the pulp is forced into the presses to separate the gold-bearing solution from the slimes, weak wash solution or water being subsequently forced through the cakes to displace the remaining gold-bearing solution. In the second method the solution of the gold is effected entirely in the filter presses, without previous agitation with KCy solution, by first charging the press with slimes and then forcing cyanide solution through the slime cakes until the maximum possible amount of gold is obtained, then displacing the gold solution by weak wash or water. The cost of single-filter pressing would run about $1.50 per ton of dry slimes.

THE linings of copper converters is one of the most important matters in converter practice. During the process of "blowing up" the copper in the converter the ferrous oxide, which forms during the combustion of the matte, robs the lining of the converter of the silica it contains to form slag. As the lining is destroyed during the converting process it has to be frequently renewed. The material from which converter linings is made is quartz and clay, the latter acting merely as a cementing medium to hold the grains of quartz together, as it must stand the force of the blast and the surging of the molten metal. The quartz must be pure silica, but experience has demonstrated that white barren quartz is preferable to siliceous ores. No quartz containing less than 98% silica is satisfactory. Many experiments have been made on the size of quartz grains to determine which was the best for use in converters, and it has been found that the quartz rock crushed in rolls so that it will pass a ⅝-inch punched trommel is satisfactory—the coarse and fine being mixed together. Linings made of this sort of material have been found more enduring than those of material screened to a uniform size either coarser or finer. Almost any clay of plastic nature is considered sufficiently good for the purpose of linings, fine clay not being absolutely essential. Quartz and clay are dumped in large bins, the clay having been run through a Chile mill and the quartz through breakers and rolls. Two mixtures are used. The lower sections of the converter are tamped with a mixture of two shovels of clay to ten or twelve shovels of quartz, mixed rather dry. The upper portion is lined with a softer mixture, consisting of old crushed linings, to each ten or twelve shovels of which are added two shovels of clay. The linings are rammed in with heated bars. It requires much experience and skill to properly line a converter so it will give the best and most lasting results.

Some Structural Features of the California Gold Belt.

Written for the MINING AND SCIENTIFIC PRESS by W. H. STORMS.

A great deal has been written about the general geology, the veins, and methods of mining and milling on the California gold belt, but comparatively little has been said of some of its interesting structural features, though these often have an important bearing on the economic value and operation of the mines, where unusual geological disturbances occur. That section of the gold belt popularly known as the Mother Lode has its southern terminus near the old village of Bridgeport, in southern Mariposa county, and thence extends northerly, though not absolutely continuously through the counties of Mariposa, Tuolumne, Calaveras and Amador into El Dorado, where it splits up into a series of great vein systems, the outer limits of which are several miles apart, and the characteristic features which distinguish the lode southward are eventually lost, and the Mother Lode practically ends, though in the same general direction—N. W.–S. E.; the gold belt extends northerly, through the counties of Placer, Nevada, Butte, Sierra, Plumas and Shasta, but the vein systems of those northern counties are unlike those of the Mother Lode. The gold belt also extends southward from Mariposa county, but not with those distinctive features that characterize the Mother Lode.

The impression which has been created in the minds of those who never visited and traveled along the

Quartz Cropping—The May Rock, Mariposa County, Cal.

so-called Mother Lode, is, that it is a large and continuous vein 20 to 100 feet or more in width, and extending in a N. W.–S. E. direction for 120 miles, as indicated on the maps. Such, however, is not the case. The lode or, more properly, belt consists of a series of veins, branching, overlapping, and at places disappearing entirely, for considerable distances. Along different parts of the belt the mines are entirely dissimilar from those elsewhere, and usually the character of the inclosing rock has a material influence on the structure, if not the value, of the vein. In the two southern counties of the belt, Mariposa and Tuolumne, and extending northward into the county of Calaveras, the distinguishing characteristics of the lode are the occurrence of a great vein of dolomitic mineral consisting of the carbonates of lime and magnesia and also often of iron. When the first two are alone combined the rock is essentially dolomite, but with the addition of the iron carbonate it becomes ankerite. This rock is usually, though not always, accompanied by a green scaly micaceous magnesian mineral named by Prof. Silliman, mariposite. The dolomitic mineral is seldom gold-bearing to an extent that would constitute payable ore, though there are exceptions, the most noted being at the Rawhide mine in Tuolumne county, near Jamestown, where a small shoot of this rock (ankerite with mariposite and little quartz) was found containing several thousand dollars per ton. The dolomitic vein is accompanied by large flat lenses or veins of quartz which are occasionally gold-bearing and worked at a profit. The quartz contains, besides free gold, auriferous pyrite. The value of this rock is very variable, ranging from a few cents to many dollars per ton. The quartz occurs along the sides of the dolomitic vein, which is from 15 or 20 feet to over 300 feet in width, and sometimes large lenses of quartz are found at intermediate points between the defining walls of the dolomite. (See accompanying illustration.) Often the quartz lenses are found crossing the lode at an angle. Small quartz veins and veinlets are of frequent occurrence, connecting the larger quartz masses. Free gold is not infrequently found, and occasionally pockets containing many thousands of dollars are discovered at points from the surface to 2000 feet deep.

It is not an uncommon thing to find the pay shoots crossing the lode, sometimes reaching from wall to wall, and again having a lesser extent, reaching only part way across. The wall rocks are greatly variable in these southern counties of the lode, and are, variously, black clay slate, serpentine, amphibolite schist, diahase, talc (altered serpentine), and the dolomitic material is itself often found sheared and altered to a scaly or schistose talcose mineral. Besides the above-mentioned rocks, there appear at various places large feldspathic dikes, as at the Grant mine on Moccasin creek and at the Eagle–Shawmut, near Jacksonville. Diorite also is occasionally seen, and in the Golden Rule at Stent a diorite dike has divided the dolomitic vein into two sections. The payable values at the latter mine, however, and at the New Era and Jumper, adjoining it, are not in the dolomite or the quartz veins accompanying it, but in the hanging-wall amphibolite schists, accompanied by an intrusive dike.

From its first appearance in southern Mariposa county the lode extends uninterruptedly northward several miles to Mount Ophir, near which a break occurs—that is, the lode proper disappears, but is found cropping farther northward in the same general direction. From there it is practically continuous to the Merced river, but on the north side of the river it again disappears, to again crop up several miles beyond. Other breaks occur between the Virginia mine, 5 miles south of Coulterville, and the Grant mine, on Moccasin creek, though where the great vein does appear it forms great masses of the dolomite with its accompanying quartz ledges, which outcrop to the height of 50 to 80 feet in places above the surrounding rocks, forming prominent features of the landscape.

These breaks in the continuity of the lode are not due to faulting, but to a thinning out of the vein and its reappearance at a greater or less distance beyond. In Tuolumne county it is practically continuous entirely across the county and several noted mines occur along its length. In a general way, these mines bear a similarity to one another, though no two are exactly alike. Moreover, the best values are not always found within the lode proper, but in the schists of the hanging wall. Several mines are being operated where this is the case. To what extent the mineralization of the schists has been influenced by the main fissure it is impossible at present to say.

When the lode crosses the Stanislaus river into Calaveras county it branches into several sections, and at the top of Carson hill (a mile from the river) the dolomitic vein practically disappears, though several large quartz veins mark its continuation northward toward Angels. From the summit of Carson hill northward the dolomitic vein does not reappear northward until near San Andreas—a distance of about 16 miles. The intervening section consists chiefly of amphibolite schists, with dikes of diorite and diahase, with occasional strips of clay slate, but the most extensively developed mines are in the schists. Large veins of quartz occur throughout this region, spreading out over a width of 3 miles near Angels, but the best values are found near the center of the belt in the town of Angels. Prospects are found in many places east and west of the main lode at Angels, but as yet no paying mines have been developed therein.

Near San Andreas, as above stated, the dolomitic vein reappears, and possesses the same features as those distinguishing it southward, viz., the broad zone of dolomite or ankerite, with its ferruginous red croppings, large quartz masses, cropping boldly above the surface, and always accompanied by the more or less abundant mariposite.

From San Andreas northward these features distinguish the lode for a mile or more. It is important to note that this dolomitic vein is almost invariably accompanied by serpentine, wherever it appears, though other rocks, such as diahase tuff, diabase dike rock or black slate, may also be present.

In northern Calaveras county, beyond this reoccurrence of the dolomite, the lode is confined chiefly to black slate, with occasional greenstone tuffs, as at the Gwin mine, where at the surface the vein is entirely in black slate, but in depth encounters a coarse, much-sheared diahase conglomerate. The Gwin vein is a large, strong fissure without fault, and is remarkably straight in its strike. Following the lode northward from the Gwin into Amador county, at the southern end it is split up into numerous branches, some of which are of large size. These veins occur in black slate or in amphibolite schist, or in part at contact of these two formations. One of the distinguishing characteristics of mines in this section is the occurrence of mispickel (arsenical iron sulphide) rich in gold and often accompanied by pockets of heavy gold. The veins which here occur on the easterly side of the belt, as at the Amador gold mine, near Jackson, and in the Hardenburg, show great movement. The quartz is often highly polished along its walls, and not infrequently it has been reduced to a sandy condition by heavy pressure and movement. Heavy gouges occur which represent the crushed and ground-up portions of large masses of slate and amphibolite schist. The gouge often contains fragments of vein quartz and infiltrated veinlets of quartz and calcite. Although gold occurs in these large veins, no remunerative mine has yet been developed there, though a number of the pocket mines farther south have yielded handsomely.

Near Jackson, in Amador county, the vein system is not complex, being represented by several fissures having a nearly parallel strike. The most easterly is developed in the Zeila mine, which is nearly wholly in amphibolite schist. This mine has been operated almost continuously for more than thirty years.

(TO BE CONTINUED.)

Tungsten, Molybdenum, Uranium and Vanadium.

According to the report to the United States Geological Survey for 1902 by J. H. Pratt, the production of crude tungsten ores during 1902 amounted to 183.5 tons, of which not more than a few tons were sold. The production of 1901 was 179 tons of concentrated ore, valued at $27,720. The larger part of the production of 1902 was from Colorado, with a smaller amount from Connecticut. No new localities were developed during 1902.

Almost the entire production of commercial molybdenite was by the Crown Point M. Co. of Seattle, Wash., from their property in the western part of Chelan county. The production amounted to about twelve tons. The value of the ores is very erratic, the prices quoted varying from $1500 to $100 per ton.

There was a marked increase in the production of uranium and vanadium minerals in 1902, which, as reported to the Survey, amounted to 3810 tons, valued at $48,125, or $12.63 per ton. This, of course, represents the crude ore. In 1901 the production was 375 tons of crude ore. A portion of the uranium ore was treated, giving a concentrated product of twenty-five tons, which was valued at $8000, or $320 per ton.

Although it has been determined that these metals have beneficial effects when used in the manufacture of steel, considerable study of them is necessary before their commercial position with respect to one another or to nickel and chromium can be definitely determined. Questions came up as to which of the various irons hardened by them are best adapted for steel drills, for dies and shoes in stamp mills, for car axles, carpenters' tools, etc., as to which will retain the best cutting edge, which will heat the least when in use, and which will make the toughest iron.

A. B. Frenzel of Denver, Colo., has offered prizes at a number of the schools of mines in the United States for investigations of these ferro-alloys in relation to the matters mentioned above, and they would seem to offer an inviting field for investigation by the Carnegie Institution.

Production of Quicksilver in 1902.

The production of quicksilver in the United States during 1902, says Dr. J. Struthers in his report to the United States Geological Survey, amounted to 34,451 flasks of 76½ pounds each, valued at $1,500,412, as compared with 29,727 flasks, valued at $1,382,305, in 1901—an increase in quantity of 4724 flasks and in value of $118,107. California contributed the greater part of the output, amounting to 29,199 flasks, as compared with 26,720 flasks in 1901. Texas reported 5252 flasks, as compared with 2932 flasks in 1901—both States thus showing an increase in the production above that of the preceding year. Oregon, which furnished 75 flasks in 1901, reported no production during 1902, the quicksilver mining operations in that State being limited to development work.

The report contains a review, by W. Forstner, of the progress in quicksilver mining in California during 1902. As is well known, California has produced nearly the entire output of quicksilver in the United States, the quantity to be credited to that State since 1850 amounting to 1,913,258 flasks, of which the New Almaden mine, in Santa Clara county, has furnished more than 50%.

The production of quicksilver in Texas during 1902, valued at $228,620, as compared with a value of $132,438 in 1901, shows a very active development of the industry. The entire output for both years was produced by the Marfa & Mariposa Mining Co., operating at Terlingua, Brewster county.

The exports of quicksilver for 1902 amounted to 13,247 flasks, valued at $575,099, as compared with 11,219 flasks, valued at $475,609, in 1901. Of the exports, 8913 flasks, valued at $383,578, went out of the port of San Francisco, nearly one-half going to Hongkong.

Ore Grades in the Witwatersrand.

As a means of comparison in the cost of operating deep mines, and particularly as referred to the grade of ores treated, the following extract from South African mines will be of interest wherever deep mining for gold is being carried on. It is evident that the development of the mines and economy of operations are greatly hampered by a lack of native Kaffir cheap labor, to which these mines were accustomed prior to the war; and it looks as though the very deep levels of the Rand would find a condition as to excessive cost of sinking and equipment. Values found in depth and cost of operating will place them on a plane with the low-grade gold mines of the United States. These deep mines of the Rand must not only pay a profit on the running expense, but must also realize the interest on the large capital invested in purchase of the property and its equipment and development, and this sum usually will exceed $3,000,000 on the very deep levels.

Although the conglomerates of the Rand deposits are noted for consistency of grade over large areas, there is an interesting localization of gold values in different areas, so that a rich mine may have a neighbor of comparatively low grade. Stores, forwarding agencies, transport offices, the market—in a word, the township, naturally focus at the most profitable point of a gold field, and hence Johannesburg has been built on the richest portion of the fields. A line from Market Square, Johannesburg, to the farthest extremity of its outlying suburb, Fordsburg, runs parallel to reef of high value, which is worked by the Wemmer, Ferreira, Ferreira Deep, Worcester, Robinson, Robinson Deep, Bonanza, Crown Reef and Crown Deep. The outcrop mines of to-day which have absorbed smaller interests, like the Pioneer, Tribute and Mint on this line, are the richest on the fields, and all have a normal value of over 50s per ton. The Deeps of this area and the Deep-Deep producers are not as rich on the whole as the first row propositions, and this fact has, in a measure, led to the popular fallacy that Main Reef series decreases in value as a greater depth is attained. It should be remembered that the Bonanza itself, which often yielded over £5 per ton in pre-war outputs, is the deep level of the Johannesburg Pioneer, and although the term deep level is somewhat of a misnomer, in this case it is farther from the outcrop than the latter property, which had a yield of a little over £4. The Ferriera Deep is now running about 55s, and the Robinson Deep about 42s or 43s to the ton. In talking of ore grades, one must necessarily refer to values exhibited before the war, and in this context it is necessary to recollect a condition which has already been reckoned as a most important factor in the settlement of values. The use of machine drills in stopes must be carefully limited in Rand mining if the best results are to be derived from them. In pre-war days their use was largely restricted to development work—drives, raises and winzes, and, in some instances, to large ore body stopes. To-day, owing to shortage of manual unskilled labor, rock drills have been universally substituted for native hammer boys in mining both large and small reefs. The extravagance of this system is not felt nearly as much by propositions containing big ore bodies as it is in the mines of the thinner reef. In mining the large reefs there is ample play for the explosive in the drill hole without breaking any considerable amount of country rock, but among the thinner beds the breaking of a large amount of thinner quartzite is inevitable, and, in consequence, either a deterioration of ore values or an increased expenditure in sorting is unavoidable. There are two evils, and the question with the management is, "Which is the lesser?" That big low-grade proposition, the Simmer and Jack Proprietary, which had an average of yield of 34s 8d from some 1,700,000 tons, is now going about 2s per ton less, and it is noticeable that only about 50% of the waste sorted out in pre-war days is now eliminated. This is a property carrying large reefs, and a drop of a little over 6% in rejection is evidenced. Turn now to the Central Rand and the figures quoted below for high-grade properties carrying thinner reefs speak for themselves:

	MAY, 1903.		JANUARY, 1899.	
MINE.	Percentage of Waste Rejected.	Value Per Ton Milled.	Percentage of Waste Rejected.	Value Per Ton Milled.
Bonanza.....	10.50	69.72s	28.16	104.45s
Ferreira.....	22 58	53 16s	34.58	92 97s
Robinson.....	17.02	59.79s	.....	71 50s

The policy of the Ferreira and Bonanza is, then, to sort out less waste, while the Robinson rejects 17.02%, as against no elimination in 1899. Percentage depreciation of values in these mines is as follows:

Bonanza	33.2
Ferreira	42.8
Robinson	10.3

Many more instances of this kind may be cited, but the above are indicative of the depreciation resulting from machine drills mining small reefs of high value. Holes put down by manual labor are not so "strong" and do not tear as much ground as those made by machine.

These figures seem to disagree with the statement of Mr. Weldon, the Government mining engineer, contained in the Chamber of Mines' Report for 1902. "At the producing mines," says Mr. Weldon, "the percentage of waste rock sorted out on surface before milling averaged 19.012%, as against 21.95% for sixty-six mines in the year 1898. The percentage of rock sorted out at the separate mines varied from 6.669% to 34 78%. Pennyweights of fine gold per ton crushed, 9.599 (August, 1899); 10.010 (June, 1902." This points to an average rise in gold values on the Rand; but it should be remembered that the 1902 figures refer to forty-five mines only, and all these are naturally high-grade propositions. Batteries of the lower grade mines are at present dormant, since the returns from these would not justify their crushing under present conditions. For May of the present year the average yield of forty-seven Witwatersrand mines was 40.43s. Low-grade mines like the Violet, Balmoral, Bantjes, North Randfontein, Kimberley-Roodeport, Roodeport West and Grey's Mynpacht, all of which have had average yields of under 25s. per ton, are not included in the list, and it is due to this non-inclusion of properties which reduce the Rand yield aggregate that the grade returns of mines producing to-day are higher than in the ante-bellum returns. Only one—the Vogelstruis Estates—of the thirteen companies with an ore grade of under 25s that have produced gold on the Rand figured in the list. Of companies with a yield of under 30s, 25% are included, 66% of mines with a grade under 35s, 36.3% of properties with a grade under 40s, 88.8% of mines with a yield over 45s, and 100% of the propositions with a yield over 50s.

As an approximation it may be stated that, rich or poor, auriferous areas may almost be grouped according to the bounding limits of the different farms. Take Turffontein, for instance. It is here that the wealth of the Witwatersrand conglomerates seems to be concentrated. Turffontein No. 198, on the western and central portions, is the richest area in the fields. From the Wemmer to the Bonanza—in reality a semi-deep level—the average ore grade of five outcrop properties during May, 1903, was 57.15s; the grade of the deep-level proposition of this area, the Ferreira Deep, was 55.27s, and of the third row mine, the Robinson Deep, 41.83s. On the eastern portion, the Salishury, Jubilee and City and Suburban—which is also in Doornfontein—had a yield of 39.45s, and the semi-deep proposition, the Village Main Reef, goes 42.53s. The Deep-Deep representative has not yet reached the producing stage, but the strike in the Village Deep shaft seems to indicate a good grade future for the proposition. South of the properties enumerated above are large blocks of ground vested in the South Village Deep, Turf Mines, etc., not yet opened up by shafts. Going east from the City and Suburban, the next property is the Meyer & Charlton, on the farm Doornfontein, the ore grade of which is placed at 37.54s in the May analysis sheet. During January, 1899, the Wolhuter Gold Mines, adjoining the Meyer and Charlton, made a crushing of close on 34s to the ton, while the adjoining group of mines on Doornfontein, viz., New Goch, Henry Nourse and New Heriot, of the outcrops, had a yield of 39.28s per ton during May. Returns from the Jumpers are not indicative of the value of the mine under present conditions, and it should be remembered that some very high returns have been made from this property. The New Heriot is at present working under very bad conditions, and a return of just over 25s during May, 1903, contrasts very poorly with 46.41s in January, 1899. The producing Deeps of this zone give an average value of 33.47s per ton. Doornfontein, as a whole, does not contain as high values as Turffontein, and may almost be said to correspond to Langlaagte on the western portion of the Central Rand. Elandsfontein is of about the Rand average grade, 42s per ton on the western portion, but the central and eastern parts are of fairly low value. Driefontein, the adjoining farm, shows a tendency to better values in the eastern portion, containing high value properties like the Angelo and Ginsberg, but also poorer propositions, an example of which is afforded by the Balmoral. Farther east are Vogelfontein, Rietfontein and Modderfontein, on which farms not so many properties have been brought to the producing stage, but the grades of one or two propositions in this area may be cited as indicative of the values of this zone. For the first two months of 1899 the New Kleinfontein recorded an average grade of 30.9s, while the New Modderfontein yield in February, 1899, was at the rate of 39.14s per ton. Farther northeast, on Vlakfontein, the Van Ryn is situated, which recorded a yield of 28.05s in February, 1899, and has recently resumed crushing.

From the farm Langlaagte, adjoining Turffontein on the western boundary, in a westerly direction, the Crown Reef is the first mine encountered, and during last May its average yield was 49.3s per ton, while the Crown Deep's was 32.09s, Langlaagte Estate's 32.87s and Langlaagte Deep's 29.72s. And now comes the poorest part of the Rand. Through the western portion of Langlaagte, Paardekraal and Vogelstruisfontein the reef series continues perseveringly, but it is by no means as rich as it is on the eastern portion or on Roodeport, where there is a valuable zone containing propositions like the Durban-Roodeport and Roodeport United Main, with yields approximating 45s to the ton during last month. Witpoortje, the next farm on the west, is again, a low value farm, chiefly on account of the broken character of the ground and the difficulty in obtaining "unadulterated reef." Luipaardslei, with the Lancaster and Lancaster West, is of more normal value, and Randfontein's milling grade may be adjudged from the following figures for February, 1899: Porges Randfontein, 38.25s; Robinson Randfontein, 35 67s; South Randfontein, 51.36s. It is worthy of note that these three properties eliminated no waste. To approximate the milling grades of propositions as yet only proved by boreholes to be auriferous, is too much like building castles in the air. The following table shows the ore grades of properties producing during May as compared with January, 1899:

	EASTERN RAND.			
(a) Farm Driefontein—	May, 1902.		January, 1899

*From surface dumps. †Also on Turffontein.

Besides this variation in ore values along the strike of the Rand there is a fluctuation of grades along the dip, that is to say, in the different reefs. The South Reef becomes of less value as it is followed in an easterly direction from Johannesburg until on Dreifontein it is hardly mined at all. What the main Reef Leader lacks in size, as compared with the Main Reef itself, it more than makes up in richness on the Central Rand. In some properties the different banket beds are so complicated that it is extremely hard to distinguish between them, but there is certainly a localization of values along the dip analogous to the fluctuating tendency in different zones noted along the strike. The horizon occupied by the different

heds may be regarded as a negligible factor in dealing with the question of ore values, which vary directly as the conditions of chemical composition favorable to auriferous decomposition are localized. Similarly the Rand, although seemingly uniform in mineralization from far east to far west, varies in the chemical composition of its constituents in different areas. It is for this reason that localization of ore values is evident, and it accounts for the presence of a poor tract of land between the rich farms of Turffontein and Roodepoort, and for the fact that rich South Reef may overlie a poor Main Reef Leader or Main Reef.

Some Experiences of a Working Miner.

Written for the MINING AND SCIENTIFIC PRESS.

I have on several occasions in the past given your readers the benefit of some of my experiences, gained in traveling around among the mines. Some of these experiences have been instructive, some amusing, but the most of them have been of a sort teaching how things should not he done. If mining experience were all of one sort interest would fag, and there would probably he less incentive to find new and better ways of doing things, but there are all sorts of people mining nowadays, as it is a business of which one can acquire a complete knowledge in a very short time—at least so some of those engaged in mining have told me, and so, evidently others believe.

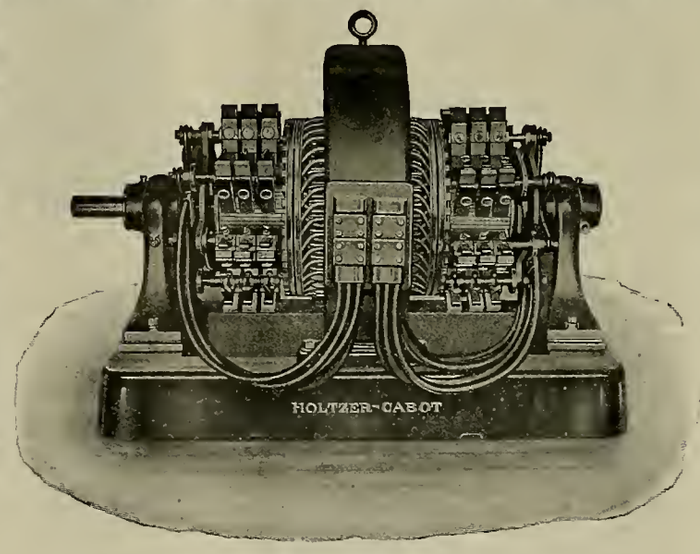
Not long since I heard a man say to another, "John, do you know I believe I will go into mining. There is more money in that than anything else I know of, unless it is a government contract—but seriously, they tell me all you have to do is to go into the hills, hunt for a vein of quartz, and that has the gold. You take this quartz—a kind of hard, white rock, you know—pound it up in an iron pot, and then wash it in the water, and there's your gold. Then all you need is a mill and you're fixed. I am going into mining, for I think I'll like it."

Now, this fellow was serious in what he said, and any one who knows anything about a mine can readily imagine the sort of miner he would make at the start. And yet, he might be lucky and strike it. A few years ago several farmers' boys located a lot of claims at R—— T—— and shipped away to the smelters a quantity of flint, rich in gold, they picked up on the surface of the ground or dug up near the surface. Trained prospectors and mining engineers had walked over the ground many a time but had not deigned to notice this ordinary rock. Half the battle is in luck, anyhow. At least, so it often seems.

* * *

A retired shoe merchant was a large holder of stock in a new mining enterprise. He had some slight knowledge of machinery and was selected by his associates for manager of the mine. These men were all Eastern people. The new manager came West, and in discussing the construction of a mill had an opportunity to show his knowledge of mechanics. The engineer suggested that it would be advisable to have a separate engine or wheel for the concentrators to insure steady and independent running. "Why, certainly," said Mr. Manager. "Why, certainly—just what I was about to suggest, and I think it would be an excellent idea to provide a separate engine for the feeders, too. We have plenty of money and intend to build this thing right." The engineer was convulsed, and scarcely knew how to put the manager straight without offending his dignity.

* * *



An ambitious young superintendent at the C—— H—— mine, who had abundance of confidence and conceit, but a small stock of experience, managed the business under him in a manner that would call for an explanation were he dealing with mining men instead of Eastern investors who knew nothing of the actual practice of mining. One of his "hobbies" was low tailings, and this was insisted on to the extent that he would go through the mill, and noticing that the concentrating machines were doing good clean work would hastily change their adjustment so as to carry in a lot of sand with the sulphides. This, of course, reduced his tailings to a value so low as to attract complimentary notice from the home office, but what of the actual result of so foolish a policy. The concentrates might contain from 2% to 5% sand, worth little or nothing—in fact the sand from an economic standpoint was valueless—but by his manipulation instead of 5%, 20% sand was carried into the concentrates, or 15% of worthless material, which was not subsequently separated, but was sacked, shipped and smelted with the sulphides. This means that in every carload of sulphurets shipped (twenty tons) there was at least three tons of sand more than there should have been. This was equivalent to an extra and unnecessary expense of about $45, including sacks, sacking, transportation by wagon and rail, reduction charges, discounts, etc., which would be a natural charge against the seventeen tons of (95% clean) concentrates, equal to about $2.65 per ton. As this mine produced about 300 tons of sulphurets monthly the foolish manager wasted nearly $800 per month. A careful manager who had the real interest of his company at heart would have endeavored to reduce the tailings to as low a grade as consistent with economy, but such machinations as that above described are criminal. This same fellow "invented" the scheme of shimming up a heavy compressor by placing soft wooden wedges between the bed plates and the concrete foundations.

* * *

The new manager at the Z—— mine at P—— was a shrewd man who watched every one about as though suspicious that each of the men under him might undertake to sieze the first opportunity to do some rascally act. He was suspicious of the foreman because he found him one morning diligently making a comparison of the month's work in the shaft with that of the previous month, when, according to the manager's idea, the foreman's place was underground helping the men. He also had a suspicion of the mill foreman because he found him in the clean-up room alone one morning weighing a lot of amalgam he had just finished cleaning, and his suspicions of the assayer were confirmed when he came suddenly upon him endeavoring to cover up his theft by pounding on the corner of a bar of gold bullion, evidently endeavoring to erase all traces of where he had chipped off a piece of the bullion for assay. He said nothing to the assayer, but confided his suspicions to the book-keeper, who suggested that possibly the assayer intended to use the little chip to determine the value of the gold bar. Gradually the new manager found he had entered upon a new world; his past experience did him little good. He had it all to learn over again. He learned rapidly and in time became a really good miner and manager. Even he laughs sometimes at the mistakes he once made, and he has a fellow feeling for others who, like himself, suddenly found themselves managers of mines with no knowledge of the business.

Electrolytic Generator.

The refinement or reduction of metals by electrolytic action has caused a growing demand for large electric generators of low voltage but relatively large output. The accompanying cut shows a generator of a capacity of 4000 amperes at an E. M. F. of 6 volts. In designing this machine the question of commutating the unusual quantity of current was determined by the use of a double armature winding with two commutators and a special conformation of field. The field ring is of cast iron. The poles—eight in number—are of wrought iron and cast welded into the ring.

Electrolytic Generator.

The armature core is relatively of large diameter, and is built up of thin discs of soft steel, painted on either side to break up eddy currents. It is mounted upon a spider, the lamination being clamped in a special manner by end plates, doing away with bolts running lengthwise through the body of the core, thus preventing local currents and reducing heat losses. The spider is provided with a threaded projection which holds the commutator in such a way as to leave an opening between the shaft and the commutator in front. Air ducts are provided in the core, and the air, being drawn into the body of the core and thrown out centrifugally through the ducts and winding, serves to keep the armature cool, notwithstanding the great quantity of current flowing. The cylindrical form of winding is used, making the armature resistance low and permitting of the replacing of a damaged coil without much difficulty. The coils are of bar copper and entirely without joint except where they are soldered to the risers of the commutator.

The commutators are made up of hard rolled copper segments, soft mica being used for insulation, and are clamped by bolts to prevent shifting of the segments. The section of the copper segments is usually large, to take care of heat generated by the flow of the current and the friction of the brushes, and at the same time allow for plenty of wear. The brush holder is of the tangent type, such as used on all Holtzer-Cabot platers.

This machine is usually separately excited, and, owing to the special shape of the pole shoes, is designed to be able to deliver any load from 0 to 25% overload without its heing necessary to change the position of the brushes, the diameter of commutation remaining practically fixed for these ranges of load. It is made by the Holtzer-Cabot Electric Co., Boston (Brookline), Mass.

The Determination of Lead in Ores.

The ordinary fire assay of lead is unsatisfactory. With most ores the results are about 2% too low, says J. C. Bull in the School of Mines Quarterly. With oxizided ores containing iron, copper, antimony and bismuth the result may be too high. Six ores were tested (1) a rich galena, (2) a poorer galena, (3) a poor cerussite ore, (4) a mixed galena and sphalerite, (5) a mixed galena and stibnite, (6) a richer cerussite. The ores were tested by (AA) ordinary assaying, following Ricketts & Miller's "Notes on Assaying," (A) gravimetrically, weighing as $PbSO_4$, (B) gravimetrically, weighing as $PbCrO_4$, (C) electrolytically, weighing as PbO_2, (D) volumetrically, by Alexander's ammonium molybdate method, (E) volumetrically, hy Koenig's method, (F) volumetrically, by the oxalate or permanganate method, (G) volumetrically, by the dichromate method, (H) volumetrically, by the ferrocyanide method. A summary of the results is as follows:

Method.	1.	2.	3.	4.	5.	6.
Fire assay (AA).....	76.0	37.0	9.0	24.7	26.7	37.8
Lead sulphate (A)...	78.65	37.23	10.75	18.42	27.23	38.52
Lead chromate (B)..	78.70	37.29	10.76	18.43	27.22	38.49
Electro. precip. (C)..	78.73	37.35	10.80	18.58	27.32	38.60
Alexander's (D).....	78.78	37.43	10.82	18.49	27.40	38.62
Koenig's (E).....	78.62	37.39	10.60	18.44	27.25	38.64
Oxalate (F).....	77.57	36.67	9.95	17.60	26.28	37.38
Dichromate fer. (G)..	78.75	37.35	10.75	18.46	27.29	38.49
Dichromate hypo. (G)	78.75	37.35	10.78	18.48	27.29	38.59
Ferrocyanide (H)....	78.66	37.30	10.88	18.46	27.22	38.62

The conclusions are that four volumetric methods for determining lead in ores deserve attention, of which it is remarked that the dichromate method is more liable to be inaccurate, unless a great deal of time is spent in washing. Koenig's method gives good results with ordinary amounts of impurities, but in some ores is unreliable. Alexander's method is quicker than the preceding and is less affected by large amounts of impurities, while the ferrocyanide method is as rapid, and not affected by even extraornary amounts of impurities, and is recommended as best.

Production of Borax in 1902.

The known deposits of borax in the United States, according to the report of Dr. J. Struthers to the United States Geological Survey, are in California, Nevada and Oregon, and the chief producer of borax and boric acid in this country is the Pacific Coast Borax Co., which owns the mines near Daggett, San Bernardino county, Cal., where the colemanite (calcium borate) is bedded in deposits from 5 to 30 feet thick. This company acquired much additional property during 1902 in the Death Valley region.

It has not been practicahle to separate the total output of borax salts during 1902 into the crude and the refined product. The reported returns, however, give an aggregate production of refined borax and boric acid amounting to 17,202 short tons, valued at $2,434,999, of which 862 short tons, valued at $155,000, were stated to be boric acid. The production during 1901 was 17,887 short tons of crude borax, valued at $314,811, and 5344 short tons of refined borax, valued at $697,307, a total value of $1,012,118.

The largest refinery in the country is at Bayonne, N. J., to which the pulverized colemanite is shipped in sacks from California.

The borax deposits of California have been described by M. R. Campbell in Bulletin No. 200 of the United States Geological Survey (1902) and by G. E. Bailey in Bulletin No. 24 of the California State Mining Bureau (1902).

Notes on the Metallurgy of Copper of Montana.*

NUMBER IV.

Written by H. O. HOFMAN.

The moist concentrates arriving from the ore-dressing plant on an overhead track are dumped into the two feed hoppers of a furnace. These are 10 feet apart and are 4 feet 6 inches in diameter for 9 feet 6 inches and then conical for 7 feet 6 inches. At the bottom they are 3 feet 6 inches by 1 foot 2 inches, to fit the openings in the roofs of the furnaces. The top of the hopper has a grating to break up any lumps and to keep out large pieces that may have accidentally gotten into the ore. The hopper holds two cars of concentrates, or 33 tons. This weight, pressing downward, prevents any hanging of the charge and thus solves the difficulty of feeding moist fine concentrates. The contents of the hopper are continuously discharged into the furnace by means of a feeding device of the form of an I, which passes to and fro under the mouth with a throw of about 10 inches. The rods of the two feeders are joined by a crosspiece which is pivoted in the center and connected by a rod to one end of a link, while the other end is attached to the pitman of a crank and spur wheel. The spur wheel is geared to the central shaft of the furnace. The ore is spread on the top hearth to the thickness of 3 inches by the stirring arms. The tops of these arms are protected by cast iron caps against rapid wear at the places where they strike the ore column coming down through the feed openings. The outer half hearth is 9 inches thick, the inner 6 inches. The reasons for the difference are saving of brick, reducing of weight at center, preventing contact with stirring teeth when the hearth rises upon heating, and furnishing an offset to hold the loose working bottom (crushed limestone, sometimes flue dust and even coke dust), which is about 4 inches thick at the center and 9 inches at the periphery. The two arms of a hearth have seven and eight cast iron teeth. These are 8 inches long by 6 inches wide by ⅝ inch thick. The lower 3 inches of the teeth, which come in contact with the ore, are chilled. There is no advantage in making the teeth thicker than ⅝ inch, as they wear off obliquely to the working surface and consequently would simply offer a larger wearing surface but not lengthen the life. At the same rate that the teeth are worn off the ore builds on the loose working hearth. When they are to be renewed they are removed and a plow is slipped over the stirrer arm and moved a little toward the center after every circuit of the arm. Thus a crust is easily and surely broken up. The crusts on the second hearth are harder to break than those of the other hearths. The teeth on the top hearth last twenty-five to thirty-four days; those on the sixth six to eight months. The shorter life of the former is attributed to mechanical wear caused by decrepitation of the ore. It cannot be due to chemical action, as the top hearth serves mainly for drying, unless the moisture should cause some sulphuric acid to form, but the temperature of the escaping gases is 315° C. and the draught is sufficiently strong to show a depression of 0.3 inch of water.

Roasting begins on the second or third hearth, varying with the strength of the draft and the number of circuits that the stirring arms make. With a strong draught the heat creeps up; with one circuit in fifty-five seconds the roast begins on the second hearth, with one in seventy-five seconds on the third. As the ore passes from the first hearth through the annular opening at the center of the roof of the second hearth (protected by a cast-iron ring), it strikes a distributor which prevents any of it from passing down the shaft. During normal work three doors on the bottom hearth are left open for the admission of air. If the furnace becomes too hot, the doors on the third floor are opened more or less and thus the draught checked. While the ore drops from hearth to hearth, the upward gas current carries with it dust, and this striking the roof adheres to it in part and builds. In order to protect the arms from being worn out at these places, they are protected by cast-iron caps. When the dust has grown to a thickness of 4 inches it is removed with chisel-pointed bars. Experiments to protect the roof at weak spots with cast-iron plates has proved successful, as the dust is easily pried off. The chunks of fritted dust go to the blast furnace as welcome lump-ore; they contain only 6% of silica with ore of 30% silica, thus showing that light particles of ferric oxide are more easily carried away by the gas currents than heavy gangue. The dust collected in the settling chambers run higher in sulphur than the roasted ore.

In starting a furnace, crushed limestone is fed to form the working bottom. Then a small fire of dry, soft, i. e., long-flame, wood is started from the three side doors of the third and fifth hearths. A new furnace is brought to a dark red in three to four days, an old furnace requires only two days. Now, concentrates are fed. After charging for five to six hours, it sometimes happens that the furnace cools down too much, and this makes it necessary to start on the third and fifth floors a new fire for one and one-half to two hours; occasionally, feeding of the ore is stopped and half a ton of coal is charged. When this has come to the third hearth, the machinery is stopped and the coal is allowed to burn out. The kindling of the coal may have to be assisted by placing dry wood on the hearth. Under normal conditions a furnace does its best work when the flue shows a depression in water of 0.3 inch; if it is less, the furnace gets cool. The normal ore mixture passes through the furnace in about one and one-half hour. If the furnace gets too hot, more slimes are fed; if too cold, coarser concentrates are charged and the rate of feeding is reduced. As indicated above, the temperature is further regulated by the admission of air; closing the bottom doors drives up the heat, opening them draws it down; opening doors higher up checks the draught. The rate of feed when once settled upon is usually not altered, and the number of circuits the arms make per hour remains, of course, constant.

‖ Lower jackets only.
‖ Ore flux.

A furnace treats, under normal conditions in twenty-four hours, forty tons sulphide ore, with 35% sulphur and 10% copper, or 0.042 tons per square foot of hearth area, reducing the sulphur to 7%; roasted ore, with 14% copper treated in the same manner, retains about 10% of sulphur. The product can, of course, be varied with the speed of travel of the stirring arms. Thus, with one circuit in seventy-five seconds it is reduced to thirty tons, with one in fifty seconds it is increased to fifty to fifty-five tons.

A section of six furnaces is tended to in an eight-hour shift by one-third foreman, one furnace man, one helper, one-sixth oiler, one-ninth repair man and one trimmer.

Some of the leading facts of the roasting furnaces operated in Montana are brought together in the subjoined table:

DETAILS OF MONTANA ROASTING FURNACES.

The following partial average analysis of roasted ore represents two determinations from the average day and night samples, taken during an experimental run of fifteen days:

SiO_2, 26.9%. Cu, 18 3%, of which 9.9% was present as CuO. Fe, 30.0%, of which 17.9% was present as FeO. S, 9.2%, of which 0.81% was present as SO_3.

The matte formed in crucible fusions contained 65% copper. In comparing the roasted ore of the MacDougall furnace with that of the Bruckner furnace (size, 8 by 16 feet, one revolution in seven minutes; fifteen-ton charge in twenty-four hours; drying, two hours; burning, four hours; charging, roasting and discharging, eighteen hours) of the same plant it is found that it is reddish brown as against a dark brown (more Fe_2O_3 is formed), more porous (1 cubic foot weighs eighty-seven pounds as against 100 pounds) and finer (the rolling of the ore in the Bruckner cylinder causes particles to form pellets). In regard to flue dust, the MacDougall furnace makes much less than the Bruckner cylinder, although the amount is still great; they compare as 1 : 3 to 4.

SMELTING ORES IN THE BLAST FURNACE.—The furnaces are all of the same general type; they are oblong and water jacketed, and have a crucible partly external and partly internal, which discharges the slag-matte mixture continuously over a raised spout, whereby the blast is trapped. The matte is settled in a large forehearth, while the slag overflows, to be granulated and removed by water, or to be collected in waste-slag cars and conveyed electrically to the dump and poured.

The tendency is to increase the size of the furnaces. The smallest distance between tuyeres is 42 inches, the largest 56 inches; in one instance it was increased to 72 inches. This worked well with coarse ore, but it proved a failure with the usual run of ores which contain many fines. Thus, a screen analysis of an average sample of blast furnace ore from one important mine gave:

300	pounds	ore over 2 inches	13.3%
450	"	" 2–1 inch	20.0%
500	"	" 1–⅝ inch	22.2%
1,000	"	" under ⅝ inch	44.5%
2,250	pounds.		100.0%

Showing why such a large distance between tuyeres proved impracticable. The greatest length of furnace at tuyeres is 180 inches; this seems to be the limit with the present mode of construction of jackets. The height of the furnaces increases with the distances between tuyeres from 7 to 18 feet. But the charge in the 18-foot furnace is kept 4 feet or so below the throat, so that the actual working height is reduced to 14 feet. All furnaces are run with a top more or less hot. Temperature measurements of furnace gases in one instance showed 315° C., and a draught measurement gave a depression 0.8 inches of water. The water jackets are all made of low-carbon steel. They are two high, reaching to a short distance below the feed door, the remaining space being of brick. There are usually two jackets on a side and one on the ends; the lower tiers of side jackets only have a bosh, the amount of which is very small, while the upper tiers are vertical, as are generally the end jackets. The gasses are always drawn off above the feed floor. In one instance the top of the furnace carries a Giroux blast heater, made by the Union Iron Works of San Francisco, which raises the temperature of the blast to 150° C., and, at the same time, acts as a dust catcher, delivering the saved dust back into the blast furnace. The charge, in most works, is introduced by hand from the sides of the furnace; occasionally it is fed from the ends. In some instances, with large furnaces, putting through 400 tons charge in twenty-four hours, mechanical feeding has taken the place of hand feeding. The charge is brought by electric or compressed air traction to the side of the furnace on trucks with tilting carriages, the doors are raised

by compressed air, and the charge slid in alternately from one side and the other. This method seems to be satisfactory. At least, worked out in one large plant, it has been introduced in another with some improvements in the construction of the carriage. While it is generally maintained, and has recently been again emphasized by P. Johnson in connection with copper smelting, that the successful working of a blast furnace is much governed by the care given to feeding, it must be admitted that, considering the mechanical feeding practiced at Butte with copper ores producing siliceous slags high in lime, and at Pueblo, Colo., Murray, Utah, East Helena, Mont., with lead ores, where blow holes or uneven sinking of charges must be absolutely avoided, that hand feeding cannot hold its former monopoly, but will have to yield to mechanical devices.

(TO BE CONTINUED.)

Modern Methods in Ore Treatment by Cyanidation.*

Written by EDWIN O. WATT.

As introductory, it is necessary that a brief outline of the process by which the gold is won from the complex sulpho-telluride ore of the Kalgurli mine be given.

I will not enter into discussion as to the relative merits of the two sulpho-telluride ore treatment processes at work on the Kalgoorlie field, viz., the treatment of the unroasted ore after sliming by solutions of bromo-cyanide, as against the treatment of the ore after roasting by solutions of potassium or sodium cyanide, either in filter presses or percolating sand vats. Even if reliable costs and percentages of extractions were obtainable in each case, it would not constitute an infallible basis of comparison, as the larger plants would necessarily have an advantage in cost per ton as against the small plants, and the other conditions obtaining are in many cases dissimilar.

In the sulpho-telluride ore of the Kalgurli mine less than 10% of the gold is free, or amenable to direct amalgamation with mercury, and by direct cyanidation of the unroasted ore it does not appear possible to obtain an extraction averaging much over 50% of the gold contents. The successful treatment of the sulpho-telluride ores of the Kalgoorlie field generally constitutes a proposition demanding the best metallurgical skill available.

The ore treatment of the Kalgurli mine is briefly as follows:

The ore from the brace is tipped over grizzlies to two rock breakers, where it is broken to a size of about 2 inches, and falls into a bin. From this bin it is, after weighing, elevated to the treatment plant by an aerial tram 574 feet long, with an elevation of 97 feet. The dry ore is tipped into a bin of 300 tons capacity over six No. 5 Krupp ball mills. Provision is made for drying the damp ore through a dryer; but as most of the ore is already dry, it is seldom necessary to use it. The ore is fed automatically from the bin to the mills, which crush, approximately, twenty-five tons per twenty-four hours through a screen of forty holes to the lineal inch. From the mills the ore falls direct into a distributing screw conveyor placed longitudinally over a steel bin of 500 tons capacity placed over feed end of furnaces.

From this bin the ore is fed by fluted roll feeders into nine Edward's roasting furnaces. These feeders are worked from an eccentric which swings a bell crank, to which is attached four falls of unequal length working on a ratchet wheel on end of fluted roll. These feeders are readily adjustable to any required tonnage. The ore falls into furnaces and is at first subjected to a temperature of about 450° F, and, after passing through the roaster, discharges at a temperature of about 1170° F. A combined push conveyor and cooling floor, 4 feet wide and 170 feet long, conveys the ore from the furnaces to a crane and bucket elevator, which discharges into a mixer, where it is mixed with water and flows to the hydraulic classfiers designed on the mine. A working drawing of these is here shown. (Fig. 1.)

The purpose of these hydraulic classifiers is to separate the sand and concentrate from the slime, so that the sand, after the removal of the concentrate, may be treated by percolating solutions of cyanide in the usual way, thus obviating the necessity of reducing to slime and filter-pressing the whole product, as is usually done on the Kalgoorlie field. The slime eventually passes to the filter presses.

Each set of classifiers consists of three small inverted cones, approximately, 2 feet 6 inches, 3 feet, and 3 feet 6 inches deep. An adjustable upflow of water is admitted at the bottom of each cone, and the whole pulp flowing through is subjected to the action of this gentle upflow. The heavier particles fall through this upcast of water and discharge in a steady flow from the bottom. The lighter particles or slimes overflow at top. By increasing or decreasing the upcast, a greater or smaller quantity of ore is caused to overflow.

Slime on the Kalgurli mine is taken to mean that portion of the pulp which passes through a woven wire screen of 100 holes to the lineal inch, and sand that portion which will not pass through the same screen. The pulp before separation consists of about equal portions of these products and the gold values of each are nearly equal. Each set of classifiers will deal with over fifty tons of ore per twenty-four hours. They are small and light and have no working or wearing parts. They can be made to do almost any needful classification, and they require scarcely any attention. As designed and erected, they are a satisfactory classifier and are the result of much experimental work. The overflow from these classifiers, consisting of about five parts of water to one of slime, is distributed through launders to five settlers, which are made of steel and measure at top 13 feet by 6 feet 6 inches, and are 7 feet 6 inches deep. They are shaped in longitudinal sections, like a W, and consist of two inverted pyramids joined together near the top. A diagram of these is shown in Figs. 2 and 3. In these the slime is settled and clear water overflows at end and passes into circulation. The pulp, consisting of from 50% to 60% of slime, is drawn continuously from the two bottom taps. The necessary cyanide solution is here added, and the whole flows into a filling cone above five combined pneumatic agitators and filter press pressure tanks. From these pressure tanks the slime, after agitation by air, is charged into filter presses, where the auriferous solution is pressed out and passes to zinc extractor boxes. The slime, after being washed by having weak cyanide solution pumped through it to take away any dissolved gold mechanically held, is dumped.

The sand from bottom of classifiers passes over amalgamated copper plates, then over concentrating tables, where a small portion of concentrate is taken away.

This concentrate consists of any coarse or heavy particles and is ground to slime in a pan and passes away with the other slime. The sand passes up an air lift to sand leaching vats, where it is treated by percolating cyanide solutions for about twelve days. The solutions on these vats are, when not draining off, constantly re-circulating from bottom to top by miniature air lifts attached to the sides of the vats. As these vats are almost full with sand, and the solutions cover the sand, it follows that the solution equalizes in the little lift pipe; the actual lift over the side of the vat does not exceed 6 inches. A hole for the admission of the air at bottom of lift, $\frac{1}{16}$ of an inch in diameter, will keep a steady flow of solution passing from top to bottom of vat. These miniature lifts not only re-circulate the solutions, but they aerate them also, and they have proved very beneficial. I would recommend the use of these aerating re-circulators for cyanidation by percolation wherever it is possible to obtain the very small amount of compressed air necessary to work them.

AIR LIFTS.—Air lifts are sometimes alluded to in technical works as air lift pumps; but, while they do the work of pumps, they are not pumps, because they have no working parts, and, for all practical purposes, no wearing parts. To J. W. Archibald belongs the credit of having introduced them into Western Australia. Air lifts have been working

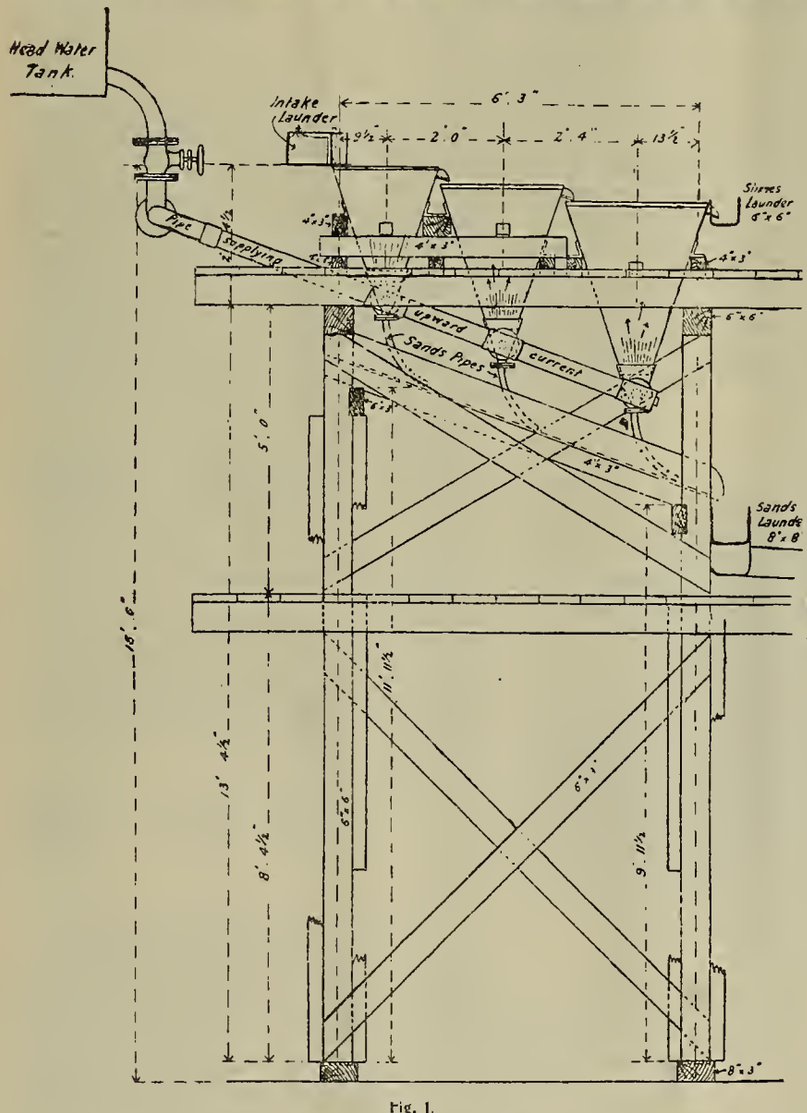

Fig. 1.

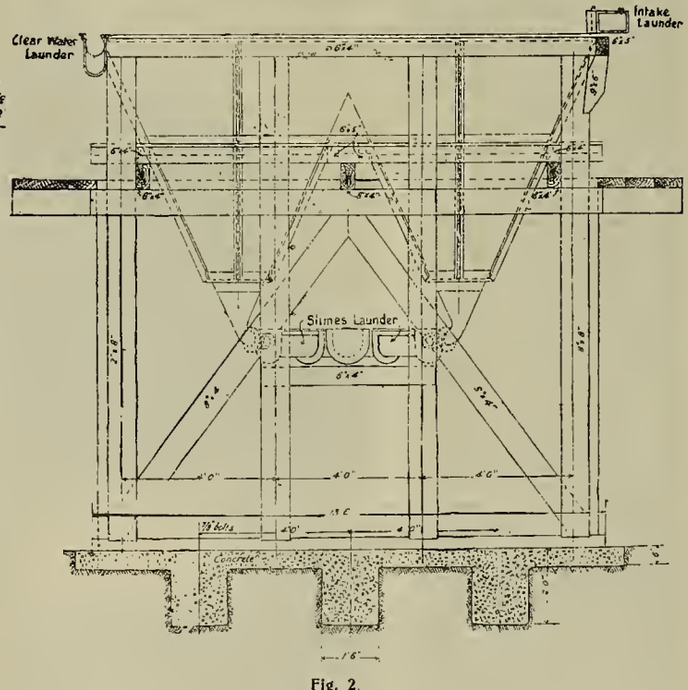

Fig. 2.

*Trans. Australian nst. Min. Engrs. (Condensed.)

under various conditions on the Kalgurli and Hainault mines for more than a year.

At present there are on the Kalgurli mine, in addition to the miniature lifts attached to the sand vats, which are very small and inexpensive to work, two 8-inch and one 6-inch lifts in constant work, and on the Hainault mine one 6-inch lift taking away the products from a 10-stamp battery, hut now being used only when the sand pump is under repair. Nearly all the ore reduction works on the field are using one or more of them.

Among metallurgists and authorities on the field it is unanimously acknowledged that, although they possess many advantages over a pump, they have proved rather expensive to work. Their efficiency on the actual steam power generated at the boilers is small. For the successful working of an air lift, the lift well should in no case be less than the height of lift above the well; but, even when these conditions obtain, the air lifts are seriously affected hy the pressure and also hy the volume of air, by the size of the air pipe and by the terminal position at hottom of lift, by the size of the lift pipe and by the consistancy of the pulp, hy the specific gravity of the ore and by the grade, i. e., the fineness or coarseness of the solids.

The fact that air lifts are influenced by so many conditions does not necessarily prove that they are difficult to work, and when properly installed no such difficulty need be apprehended; but it proves to my mind that it is not easy to find the best conditions under which air lifts work to the best economical advantage. Mr. Archihald estimates the efficiency of air lifts hy the pressure required to work them, and says "that the pressure required in pounds per square inch was approximately half the number of feet to be lifted."

In these two questions of detail I find that my experience does not coincide with that of Mr. Archibald. I helieve that the maximum pressure of air required to work an air lift is always that which will force itself through the air pipe to the bottom of the lift well, displacing the pulp.

Given that pressure, it becomes then, not a question of further pressure of air, but of volume of air. Other conditions heing equal, an air lift attains its greatest efficiency when the air pressure is just enough to carry through the pipe to the hottom of the lift well. This pressure is determined, when the air pipe is large enough to practically overcome friction, hy the depth of the well and by the specific gravity of the pulp. It may not be possihle to understand all the conditions under which an air lift works to the hest advantage, but it seems to me that an essential condition is the lightening of the water or pulp in the lift column by the introduction of air at low pressure, thus allowing the equalizing force of the outer liquid to exert an upward pressure. Under these conditions the air rises gently through the column in the form of large wads or plugs, and the pulp rises intermediately in a similar way. When the air pressure at the hottom of the lift is high, and especially when it is confined in its outlet, it will rise from the point of discharge more rapidly than the pulp can travel up the column.

Under these circumstances the air cuts through the ascending plugs of pulp and destroys the efficiency of the lift.

An 8-inch 37-foot lift, working from a well of equal depth with a 1-inch air pipe required an indicated pressure of twenty-eight pounds per square inch hetween a retention valve at the top of the well and the point of discharge at the bottom; but when this 1-inch air pipe was replaced by one of 2 inches in diameter, the lift worked more satisfactorily under the same conditions with an indicated pressure of only eight pounds per square inch. These conditions were confirmed in about the same ratio on two other lifts. On a 6-inch 20-foot lift, working from a 20-foot well, the point of the air pipe at the bottom of the column was subjected to a gradual filling up by the precipitation of sulphate of lime; hut the lift continued to work until the air pipe was almost closed, although at such times the pressure gauge between the retention valve and the bottom of lift indicated the maximum pressure of the air hehind the valve, which was sometimes 50 or 60 pounds per square inch at that time. When this pipe was pulled up and the accretion removed and the pipe replaced, the lift worked with greater economy with an indicated pressure of only 3½ pounds per square inch. This lift was working on the clear water overflowing from slime settlers. The hest results were ohtained when the air pipe was large enough to allow the air passing the retention valve to escape gently into the lift column, when the terminal of the pipe was neither enlarged nor contracted and when it did not rise ahove the hottom of the lift column.

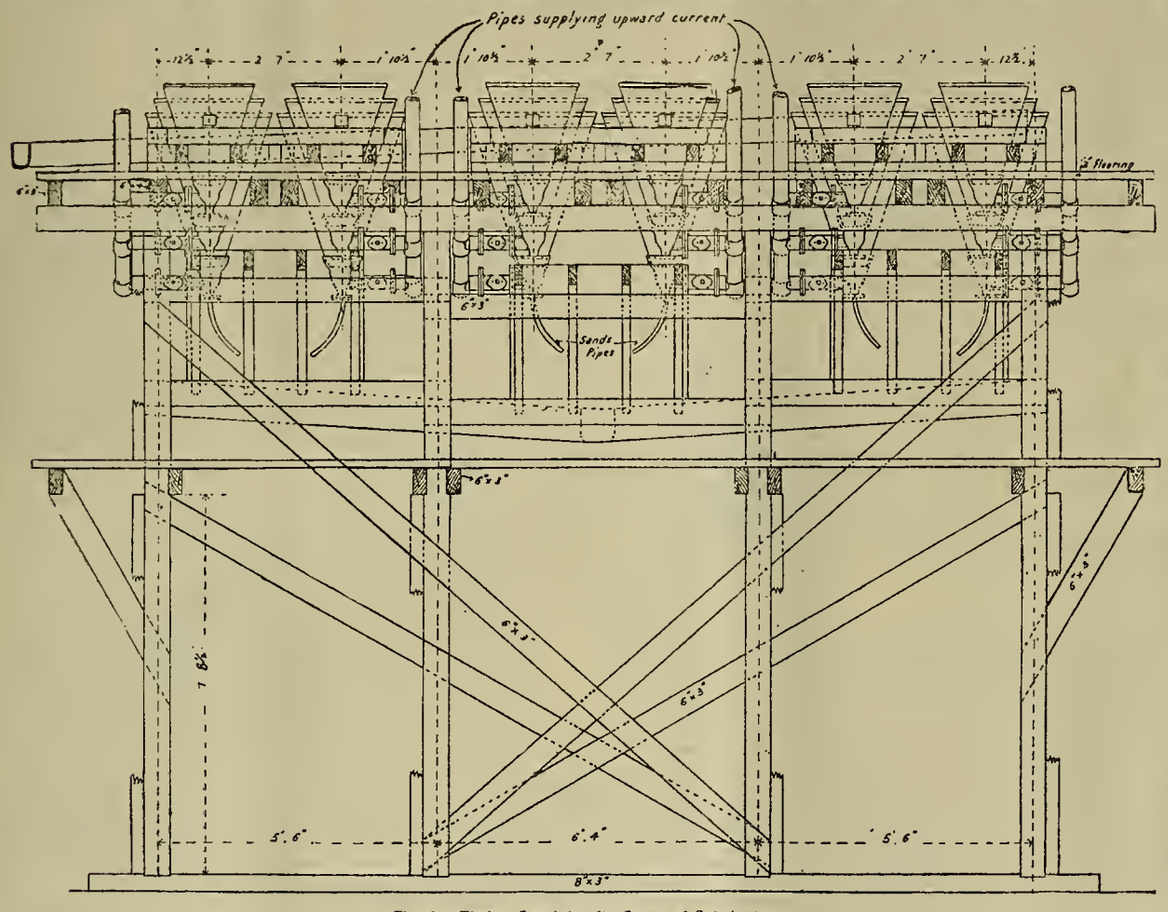

Fig. 3.—Timber Stand for Six Series of Spitzkasten.

(TO BE CONTINUED.)

Petroleum Briquettes.

A simple process has been devised at Coburg, Germany, by Mr. Maestracci for making petroleum briquettes, very much resemhling those made of coal. The modus operandi is as follows: To a liter of petroleum are added 150 grams of soft soap, 150 grams of resin and 300 grams of caustic-soda lye wash. This mixture is heated and well shaken. As soon as the mass begins to solidify, which should be in about forty minutes, the progress of the operation should be very carefully watched. To prevent the mixture running over a little soda should be poured into the vessel, shaking the whole until solidification is complete. When the operation is finished the matter is run into molds to be made into briquettes, which are then placed in a stove for ten or fifteen minutes. It then only remains to allow them to get cold, when they cau be used within an hour or two of being manufactured. By the addition of sawdust and sand the briquettes will be more solid and at the same time cheaper. From experiments said to have been conducted on tugs the inventor claims it has been clearly shown that these briquettes give three times more heat than ordinary coal, there being, in addition, the advantage of no waste remaining.

Tin in the United States.

Written for the MINING AND SCIENTIFIC PRESS.

The impost of a heavy duty on tin ore exported from the Straits Settlements, on the Malay peninsula, is likely to have an important bearing on the development of tin prospects in United States territory. Tin occurs in a number of localities in the United States, the most noted being those about the Harney Peak region and the Nigger Hill section, in South Dakota, and that in Riverside county, Cal. In the former extensive development and installation of heavy machinery at various places in the Harney Peak region has not as yet proven a commercial success, nor has it demonstrated the ability of those interested in the industry at these several places to properly and successfully handle an enterprise the character of which is, to say the least, novel—in America. At Nigger Hill considerable development has been done, and it is said good prospects have been found, but as yet no tin has heen produced in commercial quantities. In Riverside county, Cal., the Cajalco mine, on the San Jacinto estate, was equipped at large expense, and under the extravagant management failed to produce satisfactory results. At one time more than 120 men were employed, of whom but four were engaged in mining. Others were constructing roads, working gardens, building numerous houses, or putting in the elahorate plant. A mile or so distant from the mine a large force was engaged in building a dam across a gulch which was perpetually dry. The vein was small, but contained rich tin ore. The extravagances led to the closing of the mines, when about 40,000 pounds of bar tin had heen produced, and the ore was exhausted because of insufficient development. This is, briefly, the history of tin mining in the United States. At present there is said to be tin ore in the Santa Ana mountains, near the town of Santa Ana, Cal., and development is in progress. The most promising region for tin in United States territory is near Port Clarence, at and near Cape York, Alaska—promising hecause unproven; hut the stone occurs there, it is stated, in abundance, though the veins have not yet heen explored, if found.

Cape York* is located about half way hetween Port Clarence and Cape Prince of Wales. The York region extends westward from the York mountains to the extremity of Seward peninsula, an area of ahout 120 square miles. It is a plateau ahout 600 feet high, hounded on the east by the York mountains, which rise ahruptly from the plateau level to elevations of 2600 feet. Cape mountain, a sharp pinnacle of like elevation, marks its western margin. A shelving, shingle beach, not more than 100 to 200 yards wide, lies between the escarpment of the plateau and the ocean.

The larger part of the plateau is made up of jointed slates. To the west, near Cape mountain, is a helt of white limestone. Cape mountain itself consists of granite. The placer miners of the region found cassiterite in their sluice boxes, together with garnets, magnetite, gold and other heavy minerals, but the cassiterite was not recognized hy them until they learned it through reading a bulletin of the United States Geological Survey. It is reported that nearly all the streams northeast of York for a distance of 20 miles carry tinstone. Among them are the Anikovik river and all its tributaries, Kanauguk river, Baituk creek, Kinzuk creek and Lagoon creek, flowing into Bering sea, and Grouse, Buck, Yankee and York creeks, flowing into the Arctic ocean. York river is stated to be rich in stream tin, some of the gravel yielding from one ounce to one pound of tin to the pan.

In most mining regions of the world where tinstone is found granite is an accompaniment. This is the case in South Dakota, southern California and in Cornwall, England. In the latter district cassiterite is sometimes found in the slates accompanying

* See illustration on front page.

the granite, the tin replacing the feldspar developed in the slates by contact metamorphism. No acid eruptives have, as far as known, yet been found in the York region of Alaska, except the granite at York mountain, though there are large intrusions of greenstone. It is thought possible that the tin may be found associated with these greenstones, though, should this be found to be the case, the occurrence would be unusual. It is also possible that the stream tin may have been brought into the region at some subsequent time on the ice. The fact that there are a large number of boulders of rock scattered about the York region leads to the belief that the ice theory is one of considerable importance, and that the real source of the mineral may be found to be some distance away.

Flow of Water Over the Yosemite Falls.

Numerous miscellaneous measurements are made in California each year by the hydrographic branch of the United States Geological Survey on the streams that rise in the Sierra Nevadas. Measurements were recently made by S. G. Bennett, hydrographer, on the tributaries of the upper Merced river, which will be of interest to many persons who have looked upon the waters of these streams as they pour over the brink of the granite walls that form the boundary of the Yosemite valley, and have asked what is the volume of water flowing over the different falls.

This is a difficult question to answer, as the amount varies from season to season, from day to day, and even from hour to hour, according to the amount of snow and the state of the weather on the high mountains where these streams rise. These measurements, however, will answer this question in a general way, as they were made when the streams were at a stage said by the superintendent of the valley to represent the normal flow for June.

On June 24, 1903, Yosemite creek below Yosemite falls was flowing 119 cubic feet per second, or 53,400 gallons per minute.

On June 26, 1903, Merced river below Nevada and Vernal falls was flowing 853 cubic feet per second, or 382,800 gallons per minute.

One June 26, 1903, Illilouette creek below Illilouette falls was flowing 228 cubic feet per second, or 102,388 gallons per minute.

On June 26, 1903, Tenaya creek below Mirror lake was flowing 159 cubic feet per second, or 71,400 gallons per minute.

On June 26, 1903, Bridal Veil creek below Bridal Veil falls was flowing 20 cubic feet per second, or 9000 gallons per minute.

On June 26, 1903, the total flow of Merced river below the mouth of Bridal Veil creek was about 1380 cubic feet per second, or 620,000 gallons per minute, or nearly 900,000,000 gallons a day.

Electric Manufacture of Ferrosilicon.

The manufacture of ferrosilicon can only be carried on with economy in a large installation consisting of powerful electric furnaces. Those at the Livet works are of 650 H. P. each. The raw materials employed are preferably quartz, scrap iron and coke. Quartz is more suitable than sand, since the latter is often productive of obstructions in the furnace. Scrap iron and steel are to be preferred to iron ore, for the reason that, together with a pure quartz, the working proceeds without the formation of any appreciable quantity of slag. The purity of the product depends, therefore, entirely upon the care bestowed on the equipment of the works. The furnaces employed are of the resistance type, says M. A. Keller in Transactions Iron and Steel Institute of London.

As the use of high-grade ferrosilicon becomes more general the demand for electro ferrosilicon will probably increase; for the cost of production per unit of silicon is lower the higher the content of silicon in the finished product. For the manufacture of one ton of 10% to 15% ferrosilicon in the blast furnace, as much as three tons of coke are requisite, owing to the hot working and to the refractory nature of the slags. The process is thereby at once rendered too costly to compete on a large scale with the electrically produced ferrosilicon. If the additional cost of transport per unit of silicon in the case of alloys poor in silicon is considered, it may be concluded that the use of rich silicon is likely to be adopted, if solely for reasons of economy. The future of the electric furnace as applied to the metallurgical preparation of this alloy is therefore assured beyond question, and, for the reasons above mentioned, the development of the industry is likely to assume considerable proportions at no distant date.

Jade in China.

Large bodies of jade are found near Hsu-Yen on the river Ta-Yang that empties into the bay of Corea. Considerable jade is brought to that port by carts in large, rough blocks, and exported to other ports in China. It is found in a variety of colors—green, white, brown, red, etc. It is extensively used for tablets, table tops, cups, bowls, rings, bracelets, pipes, cigarette holders, carved figures, etc. It is worked by a combination of steel instruments and wet sand, the sand coming from the province of Shansi. The mines are not far from the sea and the cost of getting this stone aboard ship would not be very great.

Increasing Temperatures With Depth.

It is a well-known fact that there is an increase in temperature as depth is attained below the earth's surface. Various rates of increase have been reported and considered correct in the past. At one time it was stated to be 90 feet for each degree of increase in temperature. At another time 60 feet was supposed to represent the average depth for each degree of increase, but observations taken in deep mines in many widely separated regions show this increase to vary greatly in different regions, and in different mines in the same region. It also depends largely upon the temperature at the surface when the test is made. The temperature in the lower levels of a deep mine, no matter how well ventilated, is nearly uniform, while the surface temperature may vary 140° or more, at different seasons of the year. In some mines there are conditions which make certain levels of the mine very hot, due to chemical action, and to boiling water and steam arising through fissures which undoubtedly extend to great depth. The mines of the Comstock lode, Virginia City, Nev., is an instance of this. It is not always the deepest shaft or level in the mine that is hottest. This must be due to local causes, and to some extent to the condition of ventilation.

Following are the rates of increase in some of the deepest shafts in the world:

	Depth.	Feet Increase for 1°.
Calumet & Hecla, Lake Superior	4,580	223.7
Rand Victoria borehole	2,500	82.0
Port Jackson borehole, New South Wales	2,929	80.0
Wheeling wells, Virginia	4,462	71.6
Dolcoath mine, Cornwall	2,124	70.0
Schladebach borehole, Prussia	5,734	65.0
Baruschowitz borehole, Upper Silesia	6,573	62.1
Comstock lode, Nevada	2,230	33.0

In the case of the Calumet & Hecla mine, Red Jacket shaft, the temperature at depth of 4920 feet was 87.6° when the the shaft was first sunk, but after connection had been made with distant shafts the temperature was reduced to between 70° and 80°, averaging about 72°F. In the Tamarack mine, adjoining the Calumet & Hecla, the temperature is about 80°, but would undoubtedly be considerably higher if it were not for the large ventilating fans in use. The Tamarack shaft is 4938 feet deep, and at present the deepest shaft in the world.

Following are some temperatures in other Lake Superior mines and the depths at which they were taken:

	Depth.	Feet Increase for 1°.
Atlantic mine	907	99.5
Central mine	1,950	101.0
Conglomerate mine	617	95.0
Osceola mine	996	76.5
Tamarack mine	2,240	110.7
Quinsy mine	1,931	123.0

The mean increase is 1° in 100.8 feet. The variations among different mines are very noticeable and are due, no doubt, in large part to difference in ventilation. It is noted that those nearest the shores of Lake Superior show the lowest ratio of increase, and those farthest away show the highest.

In "Gold Mines of the Rand" Messrs. Hatch & Chalmers give the following data on deep mines in various parts of the world, showing temperature both in the strata and in the open air:

Country, Mine and Mineral Worked.	Depth in feet.	Temperature. Strata. Deg. F.	Air. Deg. F.
Belgium, Limon, coal	3,489	78	....
Austria, Adalbert, silver-lead	3,279	....	....
Prussia, Sanson, silver	2,532	....	....
England, Rosebridge, coal	2,442	93	85*
America, Comstock lode, gold-silver.	1,000	100	87
America, Comstock lode, gold-silver.	2,000	130	100

*At bottom of up-cast.

It will be noticed that the air temperature is from 8° to 30° lower than that of the rock strata itself. The temperatures in the mines of the Rand in South Africa, together with other data having a bearing on the subject, is given by "South African Mines" as follows:

Ferreira shaft: Depth.	Temperature. Deg. F.
123	62.4
221	63.4
317	63.6
409	64.6
496	64.8
572	65.1
638	65.7
698	67.1
758	69.0
808	69.1
Crown Deep shaft:	
825	66.7
906	69.5
1,030	70.7

These temperatures were taken by A. F. Crosse some years ago, and from them it would appear that the variation is somewhat less than 1° for every 100 feet. H. Jennings states that tests of the increment show only 1°F. for every 208 feet.

The following data taken from the last annual report of the Mines' Department contains interesting particulars regarding ventilation on three deep-level mines of the Rand:

	Robinson Deep.	Nourse Deep.
No. of employes	650	258 day, 10 night.
Depth of shafts	No. 1—2,498 ft. No. 2—2,449 ft.	No. 2—1,562 ft. vertical. No. 3—1,560.24 incline.
Cubic feet of air passing down down-cast per minute	30,000	42,898 (2 shafts).
Cubic feet of air passing up up-cast per minute	42,000	14,768
Temperature of air at the bottom of down-cast shaft	64°F.	No. 1—55°F. No. 2—62°F.
Temperature of air at the bottom of up-cast shaft	74°F.	No. 3—68°F.

	Rose Deep.
No. of employes	273
Depth of shafts	No 1—1,209 ft. No. 2—1,055 ft.
Cubic feet of air passing down down-cast per minute	30,000
Cubic feet of air passing up up-cast per minute	32,000
Temperature of air at the bottom of down-cast shaft	57°F.
Temperature of air at the bottom of up-cast shaft	67°F.

In the deep mines of Amador county, Cal., at 1500 to 2600 feet vertical depth, the temperature is about 80° F., varying somewhat according to condition of ventilation. The coolest places are about the down-cast shafts, and the hottest in close, poorly ventilated raises. All investigation of this interesting subject, however, has failed to establish a uniform rate of increase for all portions of the world, or even for different portions of the same region, but that there is an increase cannot be denied.

Miners' Unions and Miners' Wages.

To the Editor:—If all superintendents and foremen understood their business thoroughly, were willing to work harder than they do, and as hard as they should do to earn a proper salary, they could pay standard wages and would have little trouble with miners' unions.

If every miner was willing, faithful and competent, no employer having a practical knowledge of underground mining would object to paying the standard rate of $3 per day fixed by the miners' unions of California.

That all miners are not first-class is reasonable to suppose; that there is such a large proportion of worthless ones is hardly realized by the average miner himself. It is very forcibly brought home to any foreman starting up a mine requiring, say a hundred underground miners, for out of the first hundred engaged only about forty will prove to be good skilled men, who will, after receiving general instructions, proceed at once to perform their duties without needing advice or supervision; twenty will be ordinary, or average miners, and will need a great deal of direction and instruction; thirty will be indifferent and stupid, needing urging and pushing to get them to do anything like a fair day's work; the remaining ten will be classed by the shift boss as "not worth the powder to blow them to Hades."

Nevertheless miners' unions demand the same pay for each miner employed underground regardless of qualification or ability.

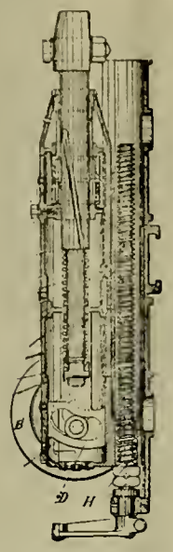
There is not the first principle of right or justice in this demand, and the miner admits it, but claims that it has to be done in self-defense; that employers cannot be trusted to discriminate fairly, and owing to the inherent selfishness, tyranny and greed of mankind, that if left to the employers' option very few men would receive even a living wage, and that the employer has as his remedy the right and privilege of discharging those who are incompetent and retaining the ones who give service.

It looks as if the only defense the mine owner has is intelligent, conscientious and fearless underground supervision.

In order to get such service better salary must be paid to compensate for the extremely hard work entailed upon one who properly performs such duty and to secure the right kind of brains and backbone. Of technical knowledge there is no lack, but handling men to advantage is not a matter of formulæ or mathematics, it is a thing by itself, and a foreman requires the use of ethnology and phrenology, as well as geology.

Improve the grade of mine foremen and you improve the miner under him. Pay the wages and see that you get the service. Chas. L. Lang.

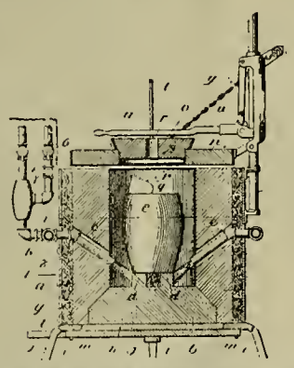
Sonora, Cal., August 17.



But six persons hold 1000 shares or over of Calumet & Hecla. They comprise Q. A. Shaw, 5500; A. Agassiz, 4904; J. J. Higginson, trustee, 4000; R. S. Oliver, trustee, 3500; C. P. Curtis, 1060; Lee, Higginson & Co., trustees, 1000. All of the above mentioned are of Boston.

Mining and Metallurgical Patents.

PATENTS ISSUED AUGUST 15, 1903.

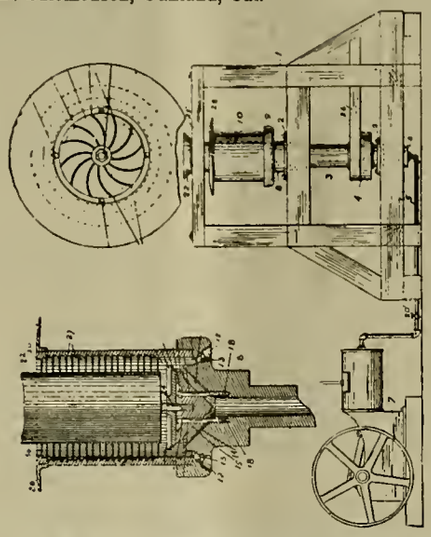


Specially Reported and Illustrated for the MINING AND SCIENTIFIC PRESS.

ROCK DRILL.—No. 735,717; H. A. Dalmas, Linden, Va.

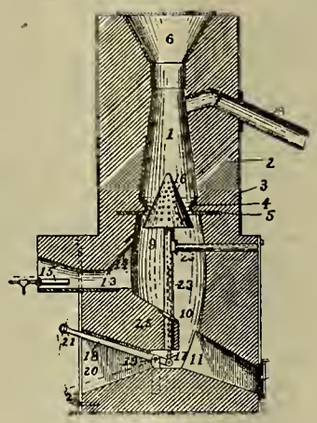
In rock drill, reciprocating crosshead, piston provided with opening therein, collar encircling piston, spring seated between collar and crosshead and key adapted to enter opening comprising shank and oppositely disposed shoulders adapted to engage collar and plunger adapted to engage collar and key whereby collar is removably locked on piston.

GAS FURNACE.—No. 735,765; P. S. Harvey, Chicago, Ill.



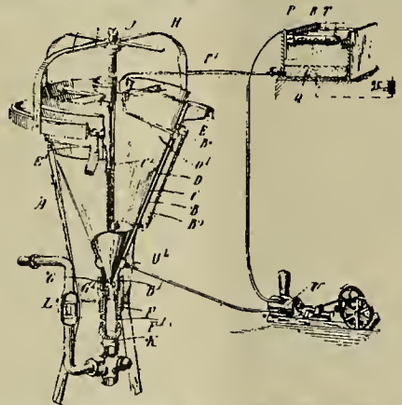
In gas crucible furnace, means for supporting crucible with space or chamber below, and means directing fuel into such chamber from side.

ROCK DRILL.—No. 735,767; P. Higgins, Beaumont, Tex.



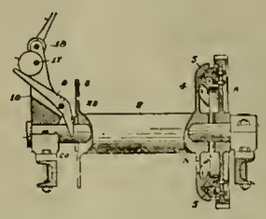
In well drilling apparatus, combination of drill barrel provided with guide, intercommunicating openings, drill slidably mounted within barrel and spaced from inner walls thereof, and having shank fitted in guide opening of plug, and stops at ends of shank for engagement with opposite ends of plug in alternation, distance between stops being regulable to vary sliding movement between drill and drill barrel.

ORE SEPARATOR.—No. 735,813; O. F. Pira and C. F. Salomonson, Oakland, Cal.



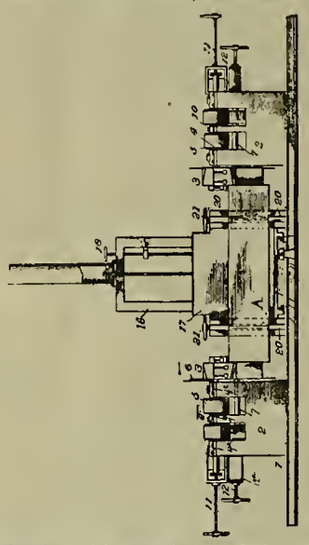
In ore separator, combination with rotatable cylinder, of centrally arranged distributing table, series riffles arranged on inner face of rotatable cylinder, means for imparting rotary motion to cylinder and distributing table, air-supply conduit discharging into cylinder, means for bodily adjusting distributing table whereby table constitutes valve for air-supply conduit, and feed pipe arranged within cylinder, through which material treated is delivered onto revolving distributing table.

QUICKSILVER FURNACE.—No. 735,919; A. A. Tregido, San Francisco, Cal.



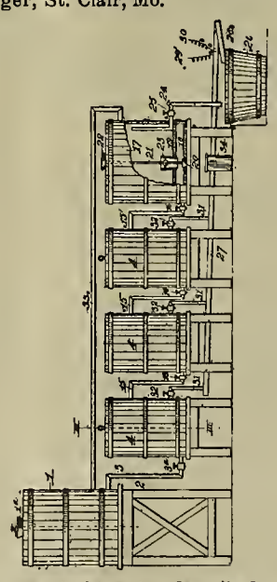
In quicksilver furnace, shaft in upper part of shell, having contracted base formed with conical seat, heat chamber below base and underlying discharge in lower part of shell, vertically movable hollow perforated cone co-operating with conical seat to close and open base of shaft to support and drop ore, opening through shell from exterior communicating with heat chamber below cone, and burner in opening.

APPARATUS FOR THE RECOVERY OF PRECIOUS METALS.—No. 736,036; H. L. Sulman and H. F. Kirkpatrick-Picard, London, England.



In apparatus for recovering precious metals, combination of vessel having inner amalgamated surface, body having outer surface amalgamated disposed within vessel and forming therewith narrow interspace, body of mercury charged with electropositive metal, inlet conduit for mercury from apparatus to top of interspace, outlet conduit for mercury from bottom of interspace to apparatus, and means for forcing solution carrying values upward through interspace.

CLUTCH FOR HOISTING MACHINES.—No. 735,862; P. F. Dundon, San Francisco, Cal.



In hoisting machine clutch apparatus, solid fixed central shaft, winding drum revoluble thereon, motor gear wheel revolubly mounted on fixed shaft at end thereof, friction clutch members on gear wheel and drum adapted for engagement, means for throwing drum clutch out of engagement, lever for moving drum with clutch member into engagement, mounted directly above fixed shaft bearing, cam, gears and crank for operating lever, also mounted above shaft bearing, whereby width of machine is practically confined within limits of drum and clutch mechanism.

MINE TIMBER-FRAMING MACHINE.—No. 735,933; C. K. Barnes and A. Y. Smith, Pearce, Ariz.

In combination with tenoning head of work support having means for clamping and centering work, means for giving proper travel for cutting purposes to support past head in straight line forward and backward, and means giving another such travel at angle to first-mentioned travel and for maintaining positions of support obtained by one travel in either direction during other travel, so that two travels may be combined in succession to constitute circuit about tenoning head.

METAL EXTRACTING AND ORE LIXIVIATING APPARATUS.—No. 735,960. G. S. Foster, St. Louis, and A. D. Stringer, St. Clair, Mo.

In apparatus of character described, combination of solution supply tank, series of intercommunicating leaching tanks adapted to receive solution from supply tank, water tank having fume conducting connection with leaching tanks, and gas conducting pipe leading from water tank to solution supply tank.

Mining Summary.

Specially compiled and reported for the MINING AND SCIENTIFIC PRESS.

ALASKA.

H Bratnoher, arrived at Dawson, says that several hundred mlners are on the verge of starvation in the northern part of Tanana district, and urges that immediate relief be furnished by the U. S. Government.

P. Johnson of Hadley, Alaska, manager, says they have men at work on the new copper smelter at the Mamie mine, owned by the Brown-Alaska C. M. Co on Prince of Wales Island. The smelter will be in operation by Jan. 1, and will have a capacity at the beginning of 400 tons a day, which it is expected to increase later on. The sawmill is in operation. Hadley is 28 miles from Ketchikan. One of the hardest troubles has been to clear the ground from timber, says Johnson. Vegetation is dense on the island, because of the mild climate and the heavy rainfall. The trees range from 2 to 11 feet in diameter.

The Alaska Con. Oil Co., J. A. Moore of Seattle, Wash., president, has men at work building a road to its holdings near Kayak. Its property adjoins the lands of the Alaska Oil Syndicate, the Lippy-Davis Co. and the English Oil Co. A drilling plant will be taken in. W. R. Brawley of Seattle, Wash., is manager of the Alaska Con. The payroll of the oil district amounts to $40,000 per month and 300 men are at work. The English Oil Co is putting up two derricks. The Abernethy-White Co., the Lippy Co. and the English Co. are all developing their holdings. The owners of the coal land propose building a wagon road from the coal mines and oil fields to supply the drilling plants with fuel and to furnish fuel at Catella and elsewhere in the district.

In Inmachuck district, at the Utica group, below Arizona creek and above Dashley Bros. group, extensive operations are being started by the owners, J. Johnson, G Shea, L. Lane et al.

The York-Alaska Tin Corporation, R. Parmele manager, have two creeks in the York district which carry placer tin deposits. Superintendent E. R. Steiner has men at work putting in a hydraulic plant to work both Buck and Onokovuk creeks.

The first quartz mill to begin operations on Seward peninsula was put in motion July 16, says the Nome Mining Gazette. The mill is on the Big Hurrah property, in the Solomon river country, near Nome, and is owned by C. D. and T. Lane. It is of ten stamps. A large quantity of ore is on the dumps ready to be crushed. The ledge has been tapped in several places.

ARIZONA.

COCHISE COUNTY.

The Gardner shaft of the Copper Queen Co., at Bisbee, is being enlarged to three compartments, the work being prosecuted from various levels by upraises. A heavy hoisting and compressor plant will be installed.

The Bisbee & Superior D. Co. has been organized, president, C. D. Shelden, of Houghton; vice-president, H. J. Vivian, of Calumet; secretary and treasurer, J. L. Nankervis, of Calumet, to operate a group of twenty-eight claims, comprising 4000 feet wide and 6000 feet long, in Tombstone canyon, 5 miles north of Bisbee. The ore bodies are found in limestone. W. Wills is in charge.

GILA COUNTY.

W. Pohl has a lease on the Tip Top No. 2, Bobby Burns and Buster mines, near Globe, and expects to begin work next week.

The four-compartment shaft of the Old Dominion C. M. & S. Co., at Globe, is down 350 feet and connection has been made at 300 feet with the sixth level of the mine, which gives good air in the shaft and facilitates sinking, says the Silver Belt. About Sept. 1 the eighth level crosscut will have been driven to connect with the shaft, and raises will be started from the tenth and twelfth level crosscuts. The electric light installation will be completed next week. Wiring the mine is progressing. At the smelter two furnaces are again running.

GRAHAM COUNTY.

The Shannon Co. continue to reduce 450 tons of ore a day, producing fifteen to eighteen tons of copper seven days in the week. The strike and cloudburst in June caused a shut down for three weeks. The mine is being developed, and it is stated the tonnage of ore in sight is on the increase. A new ore body is reported in the Black Hawk No. 3 tunnel, and a small streak of 40% ore shows in the Carter tunnel, the lowest workings of the mine.

MARICOPA COUNTY.

S. Hubbard and associates have bonded the Minerva group, near Wickenburg. This group adjoins the Goldberg properties in Black Rock district. Sinking will be commenced.

The Caledonia group of mines have been bought by C. W. Stewart of Los Angeles, Cal. These mines are 3½ miles from the Gila river and adjoin the Arizona-Pacific C. Co.'s properties, near Phœnix.

MOHAVE COUNTY.

The Treasure Hill Co. is sinking its shaft on the mine near Kingman, but the presence of an increasing volume of water is quite a detriment, as hoisting is done by whim, says the Kingman Miner. The shaft is down 125 feet and should the casing of one of the veins be broken a pumping plant will have to be put in before further work can he done.

C. T. English of St. Paul, Minn., consulting engineer for the Minnesota & Arizona G. M. Co., says that company has determinad to utilize falls in the Colorado river, 25 miles below the Grand canyon, for the estimated development of 23,000 horse power. The purpose is to furnish cheap power for the operation of several groups of mines in the desert on the Arizona side of the Colorado river, north and west of Kingman.

The Sorpresa G. M. & M. Co. has been organized by R. A. Gurley, C. Baylor, A. F. Judson, G. C. Davis and D. Sullivan of Denver, Colo., to operate sixty claims 3 miles south of Kingman, on which it has started work. A 3-mile pipe line to convey water from a spring in Railroad canyon to the mines will be laid and a 20-stamp mill will be built.

PIMA COUNTY.

F. V. Swinney has bonded the property of the Arizona O. & M. Co. in Davidson canyon, near Tucson.

The Azurite mine, 20 miles south of Tucson, has been bonded by L. Zeckendorf & Co. for $50,000, says the Bisbee Review. There are thirteen claims in the Azurite, carrying a low-grade copper ore.

YAVAPAI COUNTY.

At the Decatur mine, near Jerome, Superintendent Owens has overhauled and reset the machinery, resuming development this week.

The Ideal M. Co., operating at Groom Creek, is preparing to put up a reduction plant, which will comprise a steam stamp, with capacity of fifteen tons of ore per day, and a concentrator. E. L. Sharpneck is superintendent.

Plans are being drawn for the mill to be erected at the Home Run mine, near Groom creek, which has been bought by Douglas, Lacy & Co. The grading has been done. The pumps have been started in the Old King Extension mine, operated by the same company, and the drift is going ahead into the Iron King ledge.

CALIFORNIA.

ALAMEDA COUNTY.

The Pyne smelter, on Alameda Point, at Alameda, is reported to have suspended operations, because of the smoke and fumes destroying vegetation.

AMADOR COUNTY.

W. Moon, owner of the Red Cloud mine, south of Jackson, adjoining the Moore mine, says he has completed preliminary work and will start a tunnel, 500 feet south of the old workings, to strike the hanging wall of the ledge.

F. Eudey, a director of the Fremont Con. mine at Amador City, says a 20-foot vein of free-milling quartz which runs $5 per ton has been struck at the 1500-foot level, in the south drift from the Gover shaft. The framework of the mill is up and covered and the machinery is being set up. The mill is expected to be running by October 1st. The hoisting machinery at the Fremont shaft is in position and the boilers are being set.

At the Tom & Dick mine, ½ mile from Defender, it is expected work will be started next week, says the Amador Ledger. F. B. Joyce is owner.——At the Red Tape mine, owned hy Superintendent Lofstad, a shaft has been sunk 90 feet, showing ore. This is 1 mile from Defender.——At the Bunker Hill mine, near Amador City, grading for the mill was started last week.——At the Butte Basin mine work has been resumed in sinking the shaft with view of striking bedrock. The shaft is 110 feet deep, says Superintendent W. E. Stewart. It is a gravel proposition, and they expect to reach bedrock in 40 feet.

At the Kennedy mine, at Jackson, there are 300 men at work. The new hoist is ready to start. The mill is to be increased by addition of twenty more stamps, says the Amador Ledger. They have two mills completed, one of sixty stamps and one of forty stamps.

CALAVERAS COUNTY.

It is reported the South Bank mine on Indian creek, between Angels and San Andreas, will resume.

Construction work on the 20-stamp addition to the mill of the Angels quartz mine at Angels is progressing.

The Duchess mine, near Vallecito, has been closed down. This property has two tunnels and a 10-stamp mill.

At the Woodhouse mine at West Point, operations are under way, says J. B. Summers, manager. A hoist and other machinery has been put in.

Operations began at the Stockton Hill placer mine, near Mokelumne Hill, last week, says Superintendent Robinson. It is expected work will start up on the Hexter mine.

EL DORADO COUNTY.

(Special Correspondence).—The 240-ton cyanide plant that D. Frlcot is installing at the Sand Pile mill is expected to be in operation by the 15th prox.

Latrobe, Aug. 18

The tunnel at the River Hill mine, near Placerville, is completed—connection having been made last week. The length of the tunnel is 2800 feet, and several ledges were crosscut during its development, says the Mountain Democrat.

FRESNO COUNTY.

The New San Francisco Crude Oil Co. finished its No. 2 well, near Coalinga, last week, at a depth of 1300 feet. The well has not been pumped as yet.——The Penn-Coalinga well No. 2 has been finished and will be put on the pump this week. This well is opposite the Esperanza wells —— Well No. 3 of the Esperanza Oil & Gas Co. has been finished and proves to be a flowing well.——The 28 Oil Co., operating near Coalinga, is pumping its No. 8 well. No. 9 is down 1050 feet, with 11§ casing in the hole. No. 10 derrick is completed and the grade made for No. 11. Two 500-barrel galvanized iron tanks are being built near No. 9 well.

INYO COUNTY.

The Poleta mine, 6 miles east of Bishop, has been sold to W. McGregor, of Berkeley, et al. Development work will be started.

KERN COUNTY.

D. B. Newell and E. T. Garlock are putting up a plant to work the tailings of the Garlock mill, near Randsburg.—— Johnson & Jensen have reached bedrock on their placer claim and have put in a dry washer.

Owing to the shortage of water the Echo mill at Mojave has been forced to close down. The company is making preparation to develop more water.—— A. J. Martin, manager for the Flamoflume M Co., says he is arranging to put in machinery and will have twenty men at work in Jaw Bone canyon, near Mojave. A road is being built to the mine

The R. D. Robinson Oil Co. of Los Angeles will drill fifteen oil and three water wells on its Clairmont property, near Bakersfield, says the Reporter.

MARIPOSA COUNTY.

The dump at the Malvina mine, at Coulterville, is being sorted and worked at the Tyro mill, says the Prospector.

L. J. and L. E. Hanchett, of San Francisco, part owners of the Sweetwater mine, near Mariposa, report making arrangements to build a 20-stamp quartz mill at the mine.

MONO COUNTY.

In the White mountains, J. S. Stotler, with P. Blume of Tonopah, Nev., are developing the Continental group, near Furnace canyon, 6 miles from Queen and at an altitude of 8000 feet. The main ledge is 4 feet in width at the surface and carries silver-lead ore.

D. Bell and J. Aneer report having found coal in Cottonwood canyon, near Bodie. They have uncovered 9 feet of lignite croppings and have also found oil sand and fire clay.

NEVADA COUNTY.

Near Grass Valley E. C. Lawrey & Co. are putting up a 3-stamp mill at the Rose Hill mine, on Winchester hill, to be run by steam power.

The Virginia-Gold Hill mine at French Corral has been sold to G. F. Macpherson & Bro. of San Francisco. The vein carries values in copper and gold. There are three tunnels on the property, each 400 feet in length, which are said to show the vein.

N. W. Schoorel of San Francisco has bonded the Old Junction mine and adjacent locations — six in number — at the junction of the North and Middle Yuba rivers, 4 miles west of North San Juan. The Quartz Quarry G. M. Co. has been organized by N. W. Schoorel, G. B. Horsfell, D. E. Gates, N. A. Robinson and M. M. Johnson to operate the group. H. Huckins is superintendent. A road is being built to the mine, and as soon as completed a milling plant will be put in.

Superintendent C. Kent of the Last Chance mine, on Diamond creek, near Nevada City, has started up the mill.

The Menlo ledge has been struck, says Superintendent Starr of the Empire mine, near Grass Valley. Eight months ago a crosscut was started from the Omaha shaft, in the 1400-foot level, to develop the ground and cut this ledge. It is 15 to 18 inches thick and as far as observed contains low-grade ore. Work in the Omaha shaft has also been under way, which is down 1575 feet.

PLACER COUNTY.

Work on the Cash Rock mine, near Forest Hill, is progressing and preparations are being made to put in additional machinery.

PLUMAS COUNTY.

Superintendent Redstreake of the Jamison mine, near Johnsville, says he has fifty-five men employed and work is progressing. Indications are that there will be sufficient water in the supply lakes to run the mine and mill steadily till the fall rains. Most of the ore milled is being taken mostly from development made southwest of the old part of the mine.

A body of free gold ore has been found in the Bluff City mine at Quincy, says Superintendent A. E. Shinn, being opened in a prospect shaft sunk on the north end of the ledge, and 700 feet from the face of the working tunnel.

C. M. Dobson says as soon as arrangements can be made with the Round Valley Reservoir Co. for water for power purposes the work of opening up the Indian Valley group of mines at Greenville will begin, reports the Plumas Bulletin. He has arranged with the Prentiss and Blood interests by which the Indian Valley, the Union and the Summit groups, as well as some others contiguous thereto, will be consolidated. They are preparing to drive a lower tunnel from near the Short place, opposite Greenville. This is but 100 feet above the level of Indian valley and it is estimated that to open up the properties it will be necessary to drive this tunnel 1900 feet.

C. M. Dobson has bonded the Whitney-Duncan-Hook copper mine in Genessee valley, near Genessee, and will develop it. Parts of the ledge already exposed show values.

SAN BERNARDINO COUNTY.

The Gold Peak M. Co., near Victor, reports producing bullion of the value of $2500 in a nineteen-day run with five stamps.

SAN DIEGO COUNTY.

F. Harritt has a lease on the Hubbard mine, near Banner, and has begun work. ——J. D. Moulton and L. L. Wilcox are working the dump of the Ella mine by dry washing.——F. D. Jones will resume operations in the Elevada mine at Banner Sept. 1.——L. N. Bailey will resume work of drilling in the Kentuck tunnel Sept. 1.

The work of sinking the two-compartment shaft on the Helvetia mine, near Julian, is progressing with seven men, says the Julian Miner. The shaft is down 85 feet. The 10-stamp mill is running steadily, crushing ore from the High Peak.

SANTA BARBARA COUNTY.

The Union Oil Co. is planning to put in a pipe line from the summit of the Santa Rita hills, near Santa Barbara, to the beach, a distance of 15 miles.

SHASTA COUNTY.

L. W. Vaughn of Merced, president of the Stockton Con. C. M. Co., says he is preparing to open its mine on Pit river, 3½ miles below Big Bend, near Redding. There are ten claims in the group. Native copper is said to show in places. The property is remote from means of transportation and later it is proposed to put in a road or build a small smelter on the site.

SIERRA COUNTY.

Manager J. S. Herron has arranged to resume work on the Rattlesnake placers, 14 miles above Downieville, which are owned by J. Sparks of Reno, Nev.

SISKIYOU COUNTY.

C. Fry and T. McCauley have a lease and bond on the Sheba mine, and start operations this week. The mine is located on Patterson creek, north of Orofino.

J. F. Lewis is reported to have sold his interest in the Lucky Strike mine to W. H. Overton of San Francisco for $3000. It is on Cow creek, tributary to Russian creek in the Salmon country, near Fort Jones. The ledge is 3½ feet wide and carries values in free gold and sulphurets.

TRINITY COUNTY.

Work on the cyanide plant at the Headlight mine, on Coffee creek, near Trinity Center, is under way. The old plant was destroyed by fire. The capacity will be enlarged.——The Golden Jubilee mine will start up this week.

TUOLUMNE COUNTY.

The Garfield mine has been taken over

by W. W. Coe and Eastern parties interested in the Starr King mine. The Garfield is on the North Fork of the Tuolumne river, between the Grizzly and Providence mines, near Carters. It is opened by a tunnel 300 feet, connecting with a shaft sunk 100 feet. The vein is 22 inches wide. The quartz shows free gold and galena. Water can be obtained from the Seminole ditch at a height of 800 feet. There is a good millsite, but it is thought the Bonita claim, which is on the river below the Garfield, may be bought and a better site obtained.

At the Jumper mine at Stent connection on the 500-foot level has been made with the Golden Rule mine, track laid and the shipment of ore from the Golden Rule to the Jumper mill will begin. The new air compressor is set up and is being connected with the new boiler plant. There are 125 men at the Jumper.

At the Horseshoe Bend mine, near Columbia, sixteen men are at work. The main tunnel on the ledge is in 440 feet. Two crosscuts are being driven on the ledge, one 80 feet in, with no signs of a hanging wall, says the Magnet.

At the Eagle-Shawmut mine, near Chinese, there are 285 men at work.

A. E. Hendricks has bought the Little Beauty quartz mine, near Columbia.

Preliminary work having been done on the Blue Jay and Jack Rabbit mines, near Carters, the tunnel is being driven ahead on the vein to open up the ore shoot that shows in the upper tunnels.

In the action of W. A. Nevills vs. Tuolumne Mother Lode M. & D. Co., under a decree of foreclosure, the Columbus lode claim, near Moccasin creek, and the Big Oak mine No. 1 at Big Oak Flat, together with all improvements, mills, machinery, etc., were sold at public auction by a commissioner for $10,000, being bid in by W. A. Nevills of San Francisco, Cal.

Grading for the 10-stamp mill has been completed at the Norwegian mine, near Tuttletown, and machinery is reported arriving.

S. Carlon has bought a one-half interest in the Telegraph Line mine, south of the Tuolumne river, near Groveland.——Superintendent E. C. Loftus is putting in a set of boilers at the Santa Ysabel mine, near Quartz, and it is expected operations will be resumed by Sept. 1st.

C. F. Lukens has bought a one-twelfth interest in the Belcher and Daisy quartz mines, on Turnback creek, 1 mile north of Carters; also one-sixth interest in the John W., East and West Ledge quartz mines.

At the Altadena mine, near Columbia, sinking has proceeded with a windlass to a point where other power is necessary and a steam hoist is being set up, says C. A. Holland, superintendent.

The Tuolumne County Dev. Co. has been incorporated at Carters by W. T. Carter, K. C. Parish, J. E. Conde, W. R. Hall, C. A. Holland, J. F. Summers, C. I. McLaine, G. D. Rose and C. A. Belli.

YUBA COUNTY.

To divert the Yuba river from its regular channel, near Daguerre Point, near Marysville, Colonel Heuer, U. S. engineer in charge of the river improvement, and W. W. Waggoner, State Debris Commissioner, this week awarded the contract to E. Malley of San Francisco, whose bid was 23½ cents a yard for earth work and 90 cents a yard for rock. The proposals called for bids to excavate a waterway or canal 1000 feet long with an average depth of 25 feet. This waterway will be 800 feet wide at the upper end and 600 feet wide at the lower end, and will necessitate, as estimated, the removal of 670,000 yards of earth and rock. Thirty thousand yards per month will be the minimum allowed the contractor, and two years will be required to complete the work. It is estimated the cost will reach $150,000.

COLORADO.

BOULDER COUNTY.

R. A. Duncan, part owner of the Lucky Star mine, near Wallstreet, says operations have been resumed with men at work clearing out the drifts and getting ready to take out ore. There is a shaft 400 feet deep.

CLEAR CREEK COUNTY.

H. I. Seaman of Denver, president of the Yankee Con. M. Co., operating on Yankee hill, near Idaho Springs, says the new mill is ready for operation. The crusher machinery has been put on the ground floor, and from this the ore is raised by link buckets to the ore bins. The mill has fifteen rapid-drop stamps, and it is expected to have a capacity of fifty tons a day. The mill is equipped with amalgamating tables and two sets of concentrating tables.

DOLORES COUNTY.

F. A. McNeill is developing the C. H. C. group of gold claims in Mt. Wilson district, near Rico.——The Rio Dolores M. Co. started opening up their properties at Burns this week. The company has men at work on its Santa Clara mine, and the breast of the tunnel is in a 2-foot body of oxidized iron and lead carbonate ore, says the Rico News.——The Ocean Wave M. Co. is the owner of a group of claims in Horse Gulch district, which are being opened up, and in addition to drifting on the veins a shaft will be sunk on the Ocean Wave vein. Additional machinery will be put in.

FREMONT COUNTY.

Negotiations are on between the American Federation of Labor and Western Federation of Miners for forcing the issue of an eight-hour day in the coal mines of Fremont county, says the Times.

GARFIELD COUNTY.

The Boston-Colorado Coal Co., operating near Glenwood Springs, report work progressing. Development work was started in three different points—at the mines (2 miles up the canyon), at the townsite (farther down) and at the railroad tracks (which pass at the mouth). At the same time grading was begun on a tram line to run from the mines to the shipping point. The coal deposits in the canyon are said to consist of twenty-one veins, of which three are being worked, two openings having been made in each vein. There are three separate roads of escape from each mine. The coal is found near the surface and is run out to two ninety-ton bins, from which the electric cars will be loaded. The development work has so far progressed that 1500 tons daily are being shipped and 250 miners are at work. Shipping facilities are provided by the electric tramway. The line is 2.7 miles long and has an average grade of 3½%. Trains will be made up of twenty cars, carrying five tons each, drawn by an electric motor. To guard against disaster, safety switches have been put in at two points near the lower end. These switches will always be set, and, in case the motorman has his train under full control, he will be able to turn the switch without stopping. If he is going too fast, his train will pass onto the switch and up a steep grade, which will bring the train to a stop, says the Post.

GILPIN COUNTY.

The Penobscot M. Co. has their tunnel near Rollinsville in 360 feet, and the management is considering building a mill, says the Register-Call.

Superintendent Draper of the Town Topics G. M. Co., near Central City, says arrangements are being made to sink the main shaft of the East Notaway mine from 600 feet to a total depth of 1500 feet.

Idaho Springs parties have taken a lease and bond on the John L. and Nashville mines near the head of Virginia canyon, near Russell gulch, owned by H. J. Hawley of Central City and E. W. Williams of Denver.

GUNNISON COUNTY.

It is reported that the Brooklyn M. Co. is negotiating to buy the Elko concentrator for treating its own ores which are on Galena mountain, above Elko, says the Elk Mountain Pilot.

HINSDALE COUNTY.

It is expected the Dupre M. Co., near Lake City, will, pending further development of the Tobasco mine, lease the mill of the Tobasco M. Co., to make a thorough test of the cyaniding properties of the Isolde ore, says the Lake City Times.

LAKE COUNTY.

(Special Correspondence.)—J. D. Evans, manager of the New Leadville Home M. Co., is sinking and shipping 100 tons of ore per day. This company is operating the Penrose shaft, which is 680 feet deep. Instead of sinking the main shaft from the surface they are sinking an interior shaft, by means of which it will be determined whether they have ore to justify the expense of sinking the main shaft.——C. Delker has a lease on the tailings from the A. M. W. mill and is operating in a small way. He intends adding a crusher and rolls to his plant.——The A. M. W. mill is handling 100 tons per day, and they will increase the capacity by adding Huntington mills and concentrators.

Leadville, Aug. 17.

(Special Correspondence) —No one is able to tell at present where the strike, now on in the Cripple Creek district, will end. Whether it will extend to other parts of the State is an uncertainty. Some think the mill men at Colorado City have a grievance against the United States Refining & Smelting Co., while others believe the smelter has taken the proper stand. But a majority seem to think the strike in Victor and Cripple Creek is uncalled for, as the men had no grievance. Leadville operators do not anticipate any trouble, though the closing of the Denver plants has caused some of the mines in Summit and Lake counties to suspend operations for the present.

Leadville, Aug. 17.

(Special Correspondence).—The Manhattan M. & M. Co. expect to erect a hundred-ton cyanide plant here this fall. M. L. Sargent is superintendent.

Twin Lakes, Aug. 18.

The Ten Mile M. Co., near Leadville, reports having struck the body of silver ore for which it was prospecting. It has been followed for 30 feet and has opened up to 5 feet in width, says Superintendent Shepherd. The company is putting in a pump and expects to begin prospecting in the New York mine by September 1.

The New Monarch M. Co. at Leadville will start another shaft before September 1st. The ore shoot which has been developed has been shown to extend to the northeast, and the shaft will be sunk east of the present New Monarch, says Manager Goodwin.——The Bon Air and Starr properties, which are under lease to T. S. Schlessinger, are being operated under the name of The Hague M Co, and they are taking out a considerable tonnage of iron ore——The Crown Point mine is being operated under lease to M. Starne and J. D Murphy, and a portion of the ground has been sublet to four sets of lessees who are taking out considerable iron ore.

It is expected that P. K. Connolly will have operations resumed on the Dolly B. mine in Big Evans gulch, near Leadville.

LA PLATA COUNTY.

M. McLean, C. E, and J. C. Herr of Durango, and T. Dapra of La Plata, began work last week on their group of six claims on the east side of Silver Lake gulch, near La Plata.

J. T. O'Hara has taken a lease and bond on the Yellow Eye mine, near La Plata, and will put men on next week.

LARIMER COUNTY.

President McGuire of the Grand Republic and Mount Zirkel C. M. Cos., at Pearl, says his companies will build a concentrating plant near the Mount Zirkel mine and ground will be broken by September 10th. A smelter is also proposed.——Developments continue at the Coldwater copper mine at Pearl.

PITKIN COUNTY.

Aspen reports say the fire which broke out anew in the Smuggler mine there last week has gained such headway that the management has closed the mine to let the fire burn out. The company will work the Molly Gibson mine for the present. Smoke is coming out of the Cowenhoven tunnel in great volume.

SUMMIT COUNTY.

(Special Correspondence) —E. F. Hall, Jr., manager of the French Guich M. Co., says he will put in a dredger and plant of machinery large enough to handle 3000 to 4000 cubic yards of earth per day. The company owns 350 acres of placer ground near Breckenridge and is only working part time at present, on account of the scarcity of water.——The Gold Pan Co. has closed down after a successful run during the summer.

M. W. Hoyle has a lease on the Puzzle mine and is cleaning same out preparatory to operating. The tunnel is in 2200 feet, and they are running a crosscut from the breast of the tunnel to cut another vein. The breast of the tunnel is in sulphide ore at 280 feet below the surface. He expects to put in a compressor later on.

J. B Conrad has a lease on the Atlantic claim of the Washington group, and has a shaft 25 feet deep, and reports striking a vein of ore. It will be necessary to put in a pump before sinking the shaft deeper. The property is in Illinois guich, near Dillon.

C. S. Newsom has a lease on the Washington mill and proposes to enlarge the same. He has twenty stamps dropping at present.

Breckenridge, Aug. 17.

The Oro Grande Placer M. Co. will install a steam shovel for removing the rocks from the pit, which will do away with hand work.

Dillon, Aug. 17.

(Special Correspondence).—The Tillicum M. Co. has seven claims 8 miles northeast of Dillon, in the Blue River range, 4 miles from the Continental Divide, which they are developing. The ore is low grade, but they have a large body of the same. T. Hamilton has charge of the work.

Dillon, Aug. 18.

TELLER COUNTY.

Fifty miners went to work at the El Paso Con. mine at Cripple Creek on the 19th under protection of an armed guard, part of which was furnished by the sheriff of Teller county and part by the Mine Owners' Association. Men armed with rifles are guarding the shaft house and all of the approaches to the mine, refusing admittance to all not actually employed there. This action is in the nature of a test, and if no interference is made by the union miners it is understood that a number of leading mines will attempt to resume operations at once. Provisions have been sent to the El Paso mine, it being the purpose of the operators to keep the miners on the property during the labor difficulty. Work was also resumed on the drainage tunnel under the same conditions, the union having called Superintendent Bainbridge's men out on the 13th. At the Portland mine, which employed 525 men, President Burns says he has nailed up the shaft and the property will be closed for an indefinite period. Electric lights have been placed at all points about the mine, which will be lighted at night so that no one can approach within a certain limit and not be observed. It is estimated 500 teamsters and ore handlers are out of work because of the strike. The C. K. & M., the Old Gold and the Valley City are working, as they ship to the Dorcas mill at Florence, which is union.

The Burns, Shannon and Howbert interests in the Portland mine at Victor have been sold to W. K. Ryan of New York, for the Whitney-Ryan syndicate and the Guggenheim Exploration Co, the price being reported at $5,000,000.

The Cripple Creek Enterprise M. Co., operating under the streets and alleys of Cripple Creek, have taken a lease on the Trachyte mine from the Practical M Co. They also have a block on the Deadwood mine of the Woods Investment Co., and will begin to thoroughly prospect these holdings.

J. Erisman, manager of the Blue Flag M. Co.'s mines on Bull hill, Cripple Creek, says sinking on the Blue Flag claim will be continued indefinitely. The shaft is down 100 feet. Next month they will increase their plant by two 80 H. P. boilers and heavier hoisting machinery.

IDAHO.

BLAINE COUNTY.

M. H. Lipman reports at his Point Lookout group of mines, near Hailey, the face of the drift had cut 2 feet of galena and gray copper, carrying native silver. The discovery was at a depth of 350 feet below the croppings.

The Queen Hills M. Co. has been incorporated at Halley, principal place of business at Bellevue, with J. A. Schenck, J. Rees, T. Naggs, G. D. Rees, L. T. Witty, and R. M. Barnes of Memphis, Mo., and R. B. French and D. Whitner of Bellevue, as directors.

BOISE COUNTY.

Manager Dorsey has let a contract on the Independence mine at Pearl, and has also put men to work on the Highland Mary and the Blue Bucket, that he is developing. The shaft has come into ore at 125 feet.

W. Gibbs has a lease on the Lilliputian quartz claim on Willow creek, near Idaho City, and has started work. There is a 1-stamp mill at the mine.

ELMORE COUNTY.

It is reported the Atlantic M. Co. will build a 100 stamp mill on its group near Mountainhome. The Monarch mine shaft will be sunk an additional 200 feet. A new hoisting cable 1000 feet in length has been put onto the drum. The shaft at the Monarch is down 600 feet. The company has twenty-five men at work at its mines.

The Big Lode M. Co., operating at Atlanta, will start its twenty stamps dropping this week.

A 10-stamp mill will be built at Atlanta by the Queen River Con. M. Co., says the Tribune.

LATAH COUNTY.

G. B. Dennis has secured control of the Muscovite mica mines, 15 miles from Voilmer (Troy), and expects to start operations within a month working twenty miners and about forty girls. The mine was worked regularly until 1896, when it was closed. The vein is an upright ledge between walls of mica slate and granite, 8 to 12 feet wide, the pay being continuous for 450 feet. Development consists of shaft and tunnels, 3500 feet of work having been done.

SHOSHONE COUNTY.

At Lewiston, D. T. Denton of Duluth and R. B. Hibbs have bought 200 acres of placer ground on Snake creek in the Pierce district. Mr. Denton is president of the Alder Creek M. Co. and Mr. Hibbs is the manager of the company's properties on Reed creek. It is the purpose to hydraulic in the spring.

Work has been resumed on the Happy Day, a prospect northeast of the Hercules, near Wallace.

The Sunrise M. & D. Co, whose property is northwest of the Hercules, consists of three claims owned by O. C. Smith. The tunnel is in 130 feet.

The Eagle Peaks G. M. & M. Co. has been incorporated to work mines about 12 miles from De Borgia, on the summit of the Bitter Root range. H. Topping of Newark, Ohio, is the principal incorporator.

The Toledo syndicate which has bought the Simmons-Avery group at Beartop, near Murray, will be known as the Bear-

top M. Co. Manager C. C. Groesbeck is superintending the installation of the machinery. An assay office is to be established by the company.

The Wonder M. Co. has been incorporated to operate a group of five claims 2 miles from Gem. A tunnel is being run in 150 feet to tap the ledge. Stewart & Howard of Spokane, Wash., with J. F. Howarth, P. Luela, W. A. Hostetter, J. E, Thompson, S. R. Cooper and F. P. Greene are incorporators.

The option which members of the Empire State-Idaho M. & Dev. Co. held on 30% of the Black Hawk M. Co. has been taken up. The Black Hawk is near Government gulch, near Wardner, and contains a body of high-grade galena ore. The property is being developed by a tunnel that is in over 200 feet.

The Moose Creek Placer M. Co. has been incorporated at Wallace to operate a group of placer claims on Moose creek by F. J. Short, L. L. Sweet, O. M. Gaut, J. F. Moffatt, D. Reardon, P. Rourke and K. Powers.

The Sonora M. Co. has let a contract for a 100 foot extension of its tunnel to P. Brady.

Work has been resumed on the New Hope mine, 2 miles below Osburn.

MICHIGAN.

Calumet reports say the production of copper of the Lake Superior mines in July was less than 16,500,000 pounds. There is little metal in sight for the district and it is thought some of the mines are not producing to their full capacity, and that the companies are withholding their copper until prices advance.

HOUGHTON COUNTY.

Last week the Arcadian mill, near Hancock, went out of commission, the Trimountain having shipped the last carload and the cleanup being finished. It is thought the Centennial may use the mill.

The work of ballasting the extension of the Hecla & Torch Lake Railroad to the site of the proposed shaft on the Kearsarge lode, near the northern limit of the Calumet & Hecla Co.'s property, began last week; also the laying of the 5-inch air main north from No. 7 shaft is under way.

The Osceola Con. M. Co. is operating five shafts double shift, four at the Kearsarge and No. 6 at the Osceola, near Calumet. At the mill six heads are in operation. Electric haulage may be introduced in the Kearsarge. The exploratory winze from the twelfth or bottom level of the Tamarack Junior branch of the Osceola Con. is down 336 feet from that level. Four hundred feet more will carry it to the boundary winze sunk on the plane of the lode.

ONTONAGON COUNTY.

At the Adventure mine, at Greenland, the rock at present being taken out is being sorted and the mineral yield is better than any that has been reported since the stamp mill started operations. Ten drills are being employed in enlarging the mine openings, and sinking is being confined to No. 1 and No 3 shafts. Drifting and stoping is under way in the Butler tunnel on the Evergreen lode, and three drills are opening stopes on the Butler lode. The present rock shipments aggregate 700 tons daily, as against 1500 tons which were shipped early in the year, but of higher grade.

MISSOURI.

JASPER COUNTY.

The Luke & Brown M. Co. of Carthage has been incorporated by J. Luke, J. Brown and B. Ash.

McMunnigal & Co., operating a prospect on the Burgner land, near Webb City, cleaned thirty-two wagon loads of dirt last week on hand jigs, and made 10,180 pounds of lead and 19,030 pounds of jack.——Edwards & Co, operating the Slaight & McConey mill on the Missouri Zinc Fields ground, propose to work in their own ground, as the pump will be put in operation by the Zinc Fields Co.——The Wanner L. & Z. Co. has started its mill, and an air drift is being cut from the mill shaft to the pump shaft.

Dodge & Patton are building another mill east of the Holy Smoke on the Aylor tract at Alba, which is the third mill for this firm ——The Majestic mill, north of Webb City, has been remodeled, and it is producing thirty-five tons of jack and ten tons of lead weekly, says Superintendent Nicholson.

MONTANA.

BEAVERHEAD COUNTY.

(Special Correspondence).—At the Birch Creek smelter of the Western M. Co., operating the Indian Queen mine near Dillon, Superintendent G. A. Heberlein is treating 42 3 tons of dry ore per day, and shipping twenty tons of matte every four days. The matte assays 55% copper, 30-40 ounces silver, and 0.10-0.25 ounces gold. T. F. Stevens is manager of the company.

Dillon, Aug. 17.

FLATHEAD COUNTY.

Greenough & Larson, who own mines in the Cœur d'Alene country, have a bond on the B. & B. mine at Troy, and are working thirty men. It is a silver-lead proposition and they expect to ship the ore.

At the Abbey mine, near Kalispell, the steam hoist used at the Kendall mine is being used to sink the new shaft. The future work of the company in developing the property will be decided by the results of the development work now in progress. E. Johnson is in charge.

GRANITE COUNTY.

L Evans and J. J. Fitzpatrick of Butte, who have a lease on the Southern Cross mine in Georgetown district, near Philipsburg, have bought the Twilight mill and fitted it up. The cyanide process will be used. Mr. Fitzpatrick, one of the leasers, has been experimenting with the ores from this mine for a year and believes he has solved the problem of extracting the values. The mill was started up Monday. The Southern Cross adjoins the Cable mine on the west.

The Montana G. M. Co. has again started its mill on the Sunday mine in Royal district, near Phillipsburg. The mill was closed three months ago to allow of sinking from the 120 foot level another 100 feet, and since sinking the company has been drifting and raising, says Superintendent P. C. White. This development filled the ore hins, no stoping being done hut development work being continued until there is 300 feet of work from the 220-foot station. The first stope was started last week from one of the raises, the ore being 30 inches wide and assaying $30.

Full operations are again under way at the Bimetallic mine and mill at Granite, with seventy-five men at work. The number of men in the mine will be increased. P. A. Fusz is manager.

JEFFERSON COUNTY.

The Big Indian M. Co., operating a group of mines near Basin, report having made a cleanup last week of $6300 from a two weeks run of the 60-stamp mill. From the previous fourteen days run they cleaned up $7000. At an expense of $12, 1000 tons of ore were blasted down from the pit to the ore house at one time, says the Basin Progress. The holes are hored with long augers, the ground being too soft for the use of drills. The company will start operations on a new ore body developed by the south tunnel.

LEWIS AND CLARKE COUNTY.

The Inter-Mountain reports Mrs. Gilroy has bought the Gold Coin quartz mine and has put men at developing and running a tunnel to tap the lead. The ore carries gold, silver and copper.

MADISON COUNTY.

L. D McCall has men putting up the U. S. Grant mill near Virginia City. In the mine he is driving one of the tunnels. T. Port, superintendent of the North Dakota Co which has a lease and bond on a group of claims in Hungry Hollow, has men at work opening them up.

A lease and hond has been given on the Bell and Grand Union claims, near Virginia City, to Merrill & St. Johns of Tacoma, Wash. The Bell is bonded for $25,000 and the Grand Union for $37,500. G. St. John has put men to work in the tunnel.

C. T. Weidman has bought a 5-stamp mill for his mine near Pony.

The preliminary work on the U. S. Grant mill and cyanide plant near Virginia City is progressing rapidly. The foundations are finished.

The electric drill lately installed at the Garnet Co.'s plant, 2 miles from Pony, is working and the tunnel has advanced 80 feet. It will be driven 1500 feet. Within that distance four veins will be crossed. At about 1500 feet the Galena vein will be cut at a depth of 600 feet, and 300 feet lower than the present workings. The Garnet 20-stamp mill will run on custom ore from the Bozeman, owned by the McKitterick estate, and other mines in the neighhorhood, including the Proctor-Knott group, Elkhorn and Iola.

Operations are again under way on the Old Joe group of mines on Mineral hill, near Pony. The first class ore will be shipped to the smelters, while the concentrating ore will be hauled to the Strawberry mill, 2 miles above Pony. L. B. Olds is superintendent.

PARK COUNTY.

At the Horseshoe Camp, 16 miles northwest of Cooke, the Elmen-Burke-J. de Bernard Co. of Red Lodge has secured control of 280 acres of placer ground in a gulch, and conditions are favorable for hydraulic mining. A stamp mill of 10-ton daily capacity will be placed in operation on the Klondike free-milling gold claim.

NEVADA.

EUREKA COUNTY.

The Lincoln M. Co., owning a group of lead and silver claims at Phillipsburg, in in Diamond district, 18 miles north of Eureka, has incorporated at Carson City.

HUMBOLDT COUNTY.

The mill of the Sheha M. Co., south of Mill City, is running but not to full capacity, on account of shortage of water. The lower tunnel to tap the Sheha ledge is in 790 feet and it is expected the ledge will he reached by Oct. 1st.

LINCOLN COUNTY.

The Empire Con. M. Co. has been incorporated to operate the Mountain Jewel group of mines, near Searcblght, hy W. H. Fuller and J. F. Dexter of Los Angeles, Cal., and J. Flynn, E B. Scott and H. Oster of Searchlight. Tbe Mountain Jewel group consists of five claims and the Badger group of six. A. A. Ross is superintendent.

NYE COUNTY.

The Pactolus mine, in Pactolus district, near Tonopah, has been shut down, and so far as the Salt Lake Co., which has a bond on it, is concerned, it is uncertain when operations will he resumed, says the Tribune. One thing which has been a hindrance to the development of the region is its isolation. The camp is out in the desert, where water and transportation advantages are scarce.

C. Peters says he is arranging to put in a mill of 10-ton capacity at his mine at Ellsworth, 10 miles west of Berlin. The shaft is down 50 feet and a ledge 2 feet wide carrying gold values has been opened up. Near the Peters mine, the Plute mine, owned by New York men, is being opened up. A mill with capacity of twenty-five tons a day is being put up.——Tbe Phelps-Stokes property at Berlin is working 150 men.

The Timher Hill M. & M. Co. is taking out ore for shipment to Salt Lake City, Utah, via Austin, and first shipment was made this week. The company will put on more men.——The Salt Lake & Willow Springs M. Co. is preparing to put men to work on a group of claims which have a showing of gold and copper. Timber Hill is 12 miles from San Antonio and 35 miles north of Tonopah, in the same range of mountains, says the Austin Revelille.

STOREY COUNTY.

The Con. Cal & Virginia and the Ophir mines at Virginia City have been consolidated under one management, with J. R. Ryan as superintendent.

WASHOE COUNTY.

Work on the Desert King and Wedekind mines near Reno, owned by J. Sparks, is progressing. There are thirty men employed. The work under way is development exclusively, principally sinking the main shaft, which will be put down to the 1000-foot point and drifts extended on the vein.——The Con. Nevada, owning the adjoining properties to the Wedekind mine, is meeting with delays in sinking, owing to bad air in the shaft. Plans are being made to overcome this by putting in blowers to he run by electricity. The company is also considering using a diamond drill outfit.

WHITE PINE COUNTY.

The Wide West M. Co. is running drifts on a body of free milling gold ore from the hottom of the winze and stoping in the upper tunnel in the Wide West mine, in Cocomungo district, near Cherry Creek, says the Cherry Creek Miner. A lower tunnel will he run 200 feet below the present workings, to tap the ledge below the level of the winze, to which an upraise will he made for air connection. The company's mill was started up this week.

The Last Hope and Columbia mines, near Ely, have been sold to the White Pine Copper Co. for $10,000. These claims show gold and copper-hearing quartz——Work is progressing at Pilot Knob, with the station at 450-foot level of the Giroux shaft being cut.

The Bimetallic group in Dolly Varden mining district, near Cherry creek, has been incorporated under Nevada laws hy Butte, Mont., and Eastern men, and will put men at work this week on its copper properties, says the Cherry Creek Miner.

NEW MEXICO.

GRANT COUNTY.

A group of the Ahhott & Mason claims, west of Stein's Pass, have been sold to the Arizona Line M. Co.

The Gem Turquoise Co., under Manager Parker, is operating in the Burro mountains, near Silver City. Several new turquoise mines are being developed in the central Burro district.

LINCOLN COUNTY.

The mill at the Helen Rae mine at White Oaks is being repaired preparatory to resuming work, says the New Mexican. Additional machinery has been placed in the mine and an improved method for treating the ores installed. Work is also to be resumed on the Parsons mine.

A strike of oil is reported made in the well of the New Mexico Oil & D. Co., near Flat Top mountain, at Carrizozo. The strike was made at depth of 320 feet.

OTERO COUNTY.

E. A. Hersperger of Alamogordo, who has a lease on the Garnett mine at Jarilla, has started operations.——E. Knight is developing a manganese mine near Tularosa.

SAN MIGUEL COUNTY.

The reduction plant at Tecolote was completed last week, says the New Mexican. The mill will test a new process, which is claimed to lessen the cost of treating the low-grade copper ore of the Tecolote district. It has a capacity of twenty-five tons a day. A 150-ton plant will be erected later. Standish & Matt are building a lixiviating plant to treat low grade copper ores.

SIERRA COUNTY.

Last week men were put to work hy the Prosper G. M. & M. Co at Hillsboro to open up the 100 and 200 foot levels. The mill has been repaired.

TAOS COUNTY.

C. Garner is developing the Hornet mine near Red River.——S M Malette is developing the Boggy lode, 3 miles below Red river.

OREGON.

BAKER COUNTY.

Work was resumed on the Golden Rule mine last week, which has been idle for four years, with A. Hillier, half owner, as superintendent. The Golden Rule is in Cable Cove district, near Sumpter. Hillier's plan of development is to ahandon the old workings and move farther down the mountain and start a crosscut, which in 400 feet is expected to tap the vein at depth of 450 feet.

Superintendent Townsend of the California mine, near Sumpter, says the mill began operations this week. The capacity will be 100 tons a day. The building and machinery were arranged to increase the capacity should conditions demand.

Chloride of silver, with some gold in the quartz, is reported struck in the tunnel being driven on the Cuba and Porto Rico group, adjoining the Midway mine, near Sumpter, by Superintendent E. P. Smith. The quartz vein has a width of 6 feet.

JOSEPHINE COUNTY.

The St. Helens & Galice M. Co., operating on Galice creek, near Grants Pass, report making preparations for completion of the reservoir at the head of the high ditch; enlarging of all ditches and flumes, putting in an additional hydraulic plant and derrick and a general increase in the facilities for operating at Galice creek, including the cutting and hauling of 25,000 feet of lumber for the next season's work; also deepening the bedrock cuts, says the Courier.

SOUTH DAKOTA.

CUSTER COUNTY.

Manager Ratte of the Ivanboe G M. & M. Co., a consolidation of the Ivanhoe and Chilcoot groups of mines, says the company is preparing to put up a steam hoisting plant, with air compressor and machine drills. The mines are 9 miles east from Custer.

LAWRENCE COUNTY.

The Columbia Commercial G. M. & M. Co. has been organized hy Deadwood and Eastern parties to operate on Polo peak, Miller gulch, 3 miles northwest of Deadwood. The company owns 260 acres surrounding the peak, on which some shallow shafts and tunnels have shown bodies of quartzite ore The company intends to build a cyanide plant later on. E. McLaughlin is president, W. McLaughlin vice-president and treasurer, and O. U. Pryce secretary.

The Canton M. Co. having struck water in the shaft being sunk on its Canton vein, near Deadwood, ceased work on the same. The tunnel which was being driven from the south end of the vein has also been stopped for the time being, and work is being done on the north end of the same vein, a mile distant from the former workings. The proposed millsite for the company is in Patterson gulch, at the extreme north end of its group, and it is from this gulch that the tunnel is being driven.

J. S. Ford and J. Thompson of Chicago, Ill., part owners in the Hercules M. Co., are arranging to resume operations at their holdings in Two Bit gulch, near Deadwood, says the Lead Call.

PENNINGTON COUNTY.

Tbe Standby mine at Rochford is idle, but it is reported that the Ajax M. Co., owner of the property, proposes to re-

sume.——The Ohio-Deadwood M. Co. is preparing to resume work on its grounds above Rochford, along Little Rapid creek.

UTAH.

BEAVER COUNTY.

Development work will be resumed at the Sheep Rock M. Co.'s properties on Indian creek, near Milford, before September 1.

The mill at the Horn Silver mine at Frisco has been started up again after a shutdown of several weeks, says Secretary Morris.

CARBON COUNTY.

The American Asphalt Co. reports operations progressing on their holdings in the White River country, near Price. Manager Barron, with headquarters at St. Louis, Mo., says he has twenty-eight six-horse teams on the road, transporting the product from its ground on the Cowboy vein, which is between the claims of the St. Louis company. The product of these mines (gilsonite) is used by the wire manufacturers as a coating to prevent rust, and bicycle manufacturors use it for varnish and enamel.

IRON COUNTY.

W. W. Cook of Frisco, Beaver county, has taken an option on the Indigo Blue group, south of Indian peak, near tateline, for $30,000. It is stated the group shows a 3-foot vein that carries copper, gold, lead and silver.

JUAB COUNTY.

The annual report of the Yankee Con. M. Co. at Eureka shows net earnings of $18,893.60, besides an expenditure of $6000 for a compressor plant. During the year 5373 tons of first-class ore netting $16 per ton was sold, and 3059 tons of second-class which netted $4.20 per ton. L. A. Amsden continues as manager.

The South Swansea M. Co. at Eureka has given up the development of the lower levels of that property and the management has ordered the pumps withdrawn, says the Tribune, the reason given being that the ore found below is not of grade sufficient to stand the expense.

PIUTE COUNTY.

Work will be resumed on the Trapper's Pride mine in Gold Mountain district, near Marysvale, says Manager P. M. Maudsen of Salt Lake City. A. D. McLain is superintendent and has ten men at work cleaning out and will retimber the working tunnel, which has been run into the mountain 1500 feet, after which it will be extended.

SAN JUAN COUNTY.

Preparations are being made to resume operations on the International copper mine, in La Sal mining district, with S. A. King of Provo as manager.

SALT LAKE COUNTY.

The Continental M. & S. Co. has incorporated in New York, with H. M. Crowther of Salt Lake City as president and manager and G. C. Van Alstyne secretary and treasurer, to operate the Continental-Alta mine at Alta. In the crosscut from the intermediate tunnel the ore recently cut shows 42 ounces silver, 15% lead and $1 gold per ton. They also have some copper ore.

The cyanide plant on the property of the New Mammoth M. Co. in Bingham has been bought by J. M. Swem and is to be dismantled.

Operations are to be resumed at the Butterfield mines at Bingham, says the Bulletin. The low-grade ore will be hauled out through the Queen tunnel and the Queen mill will be improved by the addition of a concentuating floor and change of process.

TOOELE COUNTY.

Manager G. H. Dern of the Con. Mercur mine at Mercur says he expects to have the remodeled reduction plant in operation by the 15th, the slimes settling tanks being ready.

UTAH COUNTY.

The Black Vault M. Co. has been incorporated at Provo to operate the Dad Lander, Peter Elliott, Bishop, Huish and Judge Dana claims, in El Dorado mining district. M. M. Warner, A. Smith, N. C. Larsen; W. E. Cooper and W. P. Davis are officers.

The Milkmaid mine, near American Forks, will have a milling plant, say the owners, W. & H. Green and J. R. Reeve. There is a sufficient supply of water for a mill flowing out of the tunnel. The ores exposed in the Milkmaid carry values principally in lead, but also contain gold, silver and copper.

WASHINGTON.

KITTITAS COUNTY.

(Special Correspondence). — At Roslyn measures of bituminous coal furnish employment for many men and supply steam fuel. The output this year will be nearly 2,000,000 tons.

Under the direction of R. Young men are opening a ledge of iron ore on the Cle Elum river.

W. A. Denny and G. W. Gallagher are opening a promising group of ten copper claims along the mineralized belt from head of Tannea way to Camp creek.

The Fortune, Dolphin, La Veda, Last Chance and Copper Queen are paralleled by the Mountain View, Mammoth, W. J., Uncle Sam and Copper King claims, making a block of ground 7500 feet in length and 1200 feet in width. Throughout this territory porphyry dikes are seen cropping. The mineralized zones present the same characteristics, having lenticular masses of ore that parallel the layers of slate and the strike of the veins in the porphyry. These lenses are usually found at the junction of slate and porphyry. Insufficient development has taken place to allow of a thorough examination. Considerable ore has been shipped from this district.

East of the Cle Elum district, 25 miles, and in the north central section of Kittitas county, is the Swauk mining district. For the past twenty-five years a constant revenue has been derived from the washing of the stream gravels and talus slope. Some quartz mining has been done there, but the principal revenue of the miners has been obtained from the placer mines along Swauk, Boulder and Williams creeks. Nuggets worth $1200 have been taken out, and a great many ranging in value from $100 to $250 have been picked up. There is no authentic record of the gold taken from these placers, but it goes into the hundreds of thousands. The gold is mostly coarse, and in the talus slopes adjacent to the veins from which it was derived, is frequently angular and branching. Crystalline specimens, "leaf gold," are often found.

Placer mining is being carried on both by sluices, into which the gravel is shoveled, and by hydraulic methods. The bedrock in this section is Tertiary sandstone and shales, highly inclined, and where they have been planed off by stream action present an uneven surface, well suited to act as natural "riffles" in retaining the gold or other heavy minerals. In some cases along the larger streams the great thickness of these deposits, and the depth of bedrock below the present water flow, make them unfavorable for ordinary hydraulic mining, but where sufficiently rich gravel is found it is brought to the surface and washed. In the vicinity of gold-bearing veins, where bedrock is well above the present streams, conditions are most favorable for hydraulic mining on a large scale.

In the past quartz mining has not received much attention, but is now being taken up by men well equipped to give this branch of mining the attention its splendid surface showing seems to warrant.

Veins occur as a casing on each side of vertical dikes of diabase, and consist of quartz and calcite, usually crowded with angular fragments of shale and sandstones, which are entirely separate one from another Considerable movement has taken place as the walls of diabase forming one border of the veins are generally slickensided, with a consequent fracturing of the adjacent stratified rocks, one wall being well defined, while the opposite is usually indefinite.

Cle Elum, August 18.

STEVENS COUNTY.

Near Ryan, machinery is being put in by the American Onyx & Marble Co. at their quarries.

OKANOGAN COUNTY.

Preparations are being made by the Bodie M. Co., operating at Bodie, to put in a mill and other equipment this fall. A sawmill is on the ground. C. M. Fassett, of Spokane, consulting engineer for the company, says a cyanide plant will be built.

WYOMING.

CARBON COUNTY.

A strike is reported made in the lower tunnel of the Doane-Rambler mine at Grand Encampment. It is a 12-inch shoot of black oxide of copper in a quartz vein. The Ætna tunnel has also 18 inches of high-grade ore.

UINTA COUNTY.

At Fossil the Globe, Fossil & Idaho-Wyoming Oil Co.'s report work progressing.

FOREIGN.

AFRICA.

TRANSVAAL.

At the Barnato group of the Coronation Syndicate, in Heidelberg district, Consulting Engineer J. H. Johns says that since the intersection of the reef in No. 2 borehole on Edenkop at a depth of 267 feet, when 18 inches gave 2 ozs. 1 dwt. per ton, further investigations have satisfied the management that the reef struck was the Coronation. Shaft sinking has been temporarily stopped, but development work is proceeding. On Blinkpoort three holes are being bored and drilling is also proceeding on Viakfontein, Rietbult and Withoek. Rustfontein, Doornhoek and Grootviel are also being exploited. There are seven diamond drills proving the formations on the Coronation line.

The finding of "true diamondiferous ground near Braamfontein" is reported, says the South African Miner. Workmen employed in a clay pit while making bricks are alleged to have encountered "all the mineral associates of the precious gems." It is further stated that a gold reef runs through the ground.

The De Beers Con. Co. is preparing to resume operations at the Dutoitspan mine, near Kimberley.

AUSTRALIA.

WESTERN AUSTRALIA.

Prospecting with a diamond drill at the Great Boulder Proprietary, Edwards shaft, on the 1200-foot level, at a depth of 1240 feet from the surface, ore 50 feet to the east of the boundary was struck. The formation is schist. The vein dips west. The average width is 5 feet and the average value is $62 gold per ton. The same borehole at a depth of 1300 feet from the surface struck ore 35 feet to the east of the boundary, 420 feet south of the main shaft west crosscut. The width of the lode is 10 feet 6 inches. The vein dips 5° east from the vertical. Average assay of ore is $18 per ton. Eleven hundred feet of level has been driven to the Golden Horseshoe boundary in the south end of section 20. On the 1300-foot level in the main shaft, driving north, the lode has been found 35 feet from the crosscut. The width of the lode is 5 feet. The average is $18 gold.

NEW SOUTH WALES.

The Broken Hill Proprietary mines at Broken Hill report output for four weeks ending July 15 (including product from ores purchased)—Refinery products for same period: Fine silver, 415,383 ounces; soft lead, 4193 tons; antimonial lead (estimated), 30 tons. In consequence of temporary condensers doing satisfactory work the difficulties of the water situation have been overcome, and the mine and concentration plant are running full time. Half-yearly statements have been issued showing a profit for the six months to July 1 of £57,661; £21,532 has been expended in construction during the half year, of which amount £7422 has been on extension of coke works and £4570 for completion of the Huntington-Heberlein process, which is now in operation and treating 2500 tons weekly. Explorations in the lower levels have advanced and £20,000 has been expended in this direction during the half year. In consequence of continued drought special consideration has been given to the matter of reduction. Experiments have been made on the zinc process with the result that a plant to handle 1000 tons weekly will be built.

QUEENSLAND.

The No. 2 South Great Eastern Gold Co. at Gympie reports that the new mill of sixty stamps is in full operation, with satisfactory results.

The Brilliant Central Gold, at Charters Towers, July 30, report having crushed during month 3030 tons of quartz for a yield of 2508 ounces gold; value of cyanide bullion, £1220 ——No. 2 South Great Eastern Gold, at Gympie, July output was: Crushed 3732 tons for 3914 ounces gold, including 690 ounces from battery plates.

W. Nethercote has taken up 3000 acres of dredging ground at the junction of the Little Palmer river and the Palmer river. It is said in the early days portions of this ground were rich, and Chinese fossickers even up to the present time have been making a profit of it by their primitive methods of working, says the Queensland Government Journal.

VICTORIA.

The Ballarat Bucket Dredge Co. has been formed to work 115 acres of ground on the Yarrowee and Little Bendigo creeks, near Bendigo.

At the West Berry Consols mine, at Creswick, R. B. Squire, manager, says a new haulage shaft will be sunk to accommodate cages that will carry a two-ton load on each deck.

The Great Boulder Proprietary G. M., Ltd., at East Coolgardie, on July 28 reports prospecting with diamond drill 1700-foot level depressed borehole at angle of 43° in westerly direction have struck ore 7 feet in width, with average assay of 11½ dwts. at a distance of 1 foot west of shaft. The main lode was struck at distance of 30 feet from the main shaft at depth of 1750 feet. The total width is 50 feet, with average assay of ore at 28 dwts.

Extensive operations have been started at the mines of the Societe le Chrome at New Caledonia. They have taken on 300 men.

BRITISH COLUMBIA.

BOUNDARY DISTRICT.

The number of men at the Fife lime quarries, being operated for the Trail smelter, was increased by twenty-five men this week due to more furnaces being blown in at Trail.

CASSIAR DISTRICT.

The Atlin Claim says on Spruce creek, near Atlin, several miles of ditches are under construction for use of the Con. Spruce Creek Placers, Ltd., while results all along Spruce creek are said to be satisfactory and a large amount of gold is being recovered. On Pine creek the Pine Creek Power Co, Ltd., is at work. They have three 6-ton hydraulic derricks in operation, says Superintendent Loveridge. The company owns 600 acres, have flumes and ditches 6½ miles long and 2 miles of steel pipe; they are using six monitors It is intended to open up another pit above Discovery at an early date.

EAST KOOTENAY DISTRICT.

The Crow's Nest Pass Coal Co. is considering several improvements in the haulage system at its mines at Fernie, says the Rossland Miner. It is the intention to put an endless rope from the tipple to the mines. This will do away with the light engine work on top of the tipple.

Final payment of $11,500 on the Badger and Red Mountain claims was made last week by F. L Byron and J. E. Woods of Frank, Alberta.

It is reported that parties boring for oil near Morrissey have struck coal.

ROSSLAND DISTRICT.

Le Roi No. 2 oil concentrator at Rossland is being constructed in a series of attached buildings, five in number, and all but the first or upper sections are complete so far as the buildings are concerned, says the Review. Three carloads of machinery have been put in and the crushing plant is being set up. The plant is expected to be in operation by Sept. 1.

SLOCAN DISTRICT.

(Special Correspondence).—In the Slocan mining division, owing to the granting of the lead bounty, there has been a steady improvement in mining for some time past. More miners have been added to the number employed and still the demand is unsatisfied. Several idle properties are starting up again, and more are to follow. Over 350 men are working at the mines around Sandon, and a greater increase is looked for. Taken as a whole, the outlook is most encouraging. The organization of the mine owners is considered to be the best movement possible to protect themselves and secure stability in silver-lead mining in British Columbia.

Nelson, Aug. 15.

Work was resumed on the Echo, near Whitewater, by M. J. Halpin and H. J. Wright, who have a lease on it. —— D. Kennedy and R. Bradshaw have leased and bonded the Bachelor group and will start work this week. —— The Daphire and Champion mines on Twelve-Mile creek, near Slocan City, have been leased to Paul Hauck ——The Queen Bess mine and buildings were sold to the Bank of Montreal for $6500. The mineral claims Tiger, Deadwood, Bland No. 2, Howard Fraction and Tiger Fraction, belonging to the Slocan Lake G. & S. Mines, Ltd., were also turned over to the Bank of Montreal to cover an overdraft. —— The bonus granted on iron and steel is expected to result in the iron deposits on Crawford creek, near Slocan City, being worked at a profit.

VANCOUVER ISLAND.

About 1100 tons of coal a day are being taken out of No. 2 and No. 3 mines at Extension. As more men are being put to work daily it is expected the maximum production (1600 tons a day) attained before the strike will again be reached. The tunnel is being opened up again. The coal is sent to Ladysmith for foreign shipment.

WEST KOOTENAY DISTRICT.

(Special Correspondence). — In Fish River camp, Lardeau mining division, at the Calumet & B. C. Gold Mines, Ltd., two of the vanners are now in place and another under way. Two of the Pelton wheels are in place and the other will be installed this week. The rock crusher is now being put in place and the cam shaft and cams are set up. Ore bins are finished and a telephone system is installed from mill to mine. It is expected to have the mill completed by the 20th inst. At the Oyster-Criterion mill the rock crusher and mortars are now in place. The compressor and power house are being roofed in. Cables for tramway have arrived and the preliminary wire for hauling up the cable is strung.

Nelson, Aug. 15.

W. E. Pool reports paying $200,000 for a three-fourths interest in the Lucky

Jack mine on Poplar creek, near Lardeau. The other fourth interest is owned by E. Morgan. It is proposed to build a stamp mill on the property this season.

YALE DISTRICT.

Placer mining is reported in full swing around Erie. The north fork of the Salmon river has been staked for 7 miles, out of which claims covering half that distance have been bought up by the North Fork Placer M. Co. of Colorado men, and the Buckeye Placer Co., owned in Spokane, Wash. These two companies are jointly putting up a flume which will cost $20,000, being 3½ miles long. This flume will run the monitors of both companies. Much of the gold is found in the present bed of the creek, and the stream has to be diverted. On either side the pay ground stretches back 100 feet from the creek bed, and in addition several bench claims have been staked outside the present course on the creek, says the Spokesman-Review.

KLONDIKE.

Near Dawson good pay is reported to have been found on Last Chance creek. ——The Violet quartz claims will be worked, for which a 10-stamp mill is being set up.

MALAY STATES.

The Malay Government has imposed an additional export tax on tin ore of $30 Mexican ($11.50) per picul of 133⅓ pounds, except when it is to be smelted in the colony. The export tax was formerly $13 63 Mexican ($5.22) per picul, all the ore being smelted within colonial limits. It is thought that the new export tax will discriminate not only against foreign countries, hut also against British colonies, such as Hongkong, Australia and Ceylon; it will also act against the smelting in England or Wales of any tin ore from the oriental supply stations. Local smelters will now have a monopoly. Local tin smelters obtain tin ore with $13.63 Mexican ($5 22) export tax, while all outsiders must pay $43 63 Mexican ($16.71) per picul. Allowing 40% dross in smelting, tbis export tax alone amounts to about $333 gold per ton of smelted or pig tin.

The annual output of the world exceeds 75,000 tons, and of this more than 46,000 tons—over 51% of the whole—come from the Straits Settlements, while Cornwall produces only 5000 tons and the Australian output has similarly declined. The Dutch East Indies export 14,000 tons and Bolivia outputs 5000 tons.

MEXICO.

CHIHUAHUA.

J. Folenshy and W. Kraft of Bisbee, Ariz , have hought the Nueva Chihuahua mine for $50,000, Mexican. The property consists of forty-four pertenencias and is near the mines of the Prieto estate and the Buena Tierra.

T. L. Greer, of Chihuahua, reports the Santa Brigida mine and mill, owned by himself et al., in the western part of the State, are again in operation.

COAHUILA.

A. O. Ihlseng and J. J. Murphy of New York City have leased La Union M. Co.'s La San Salvadora and La Porvenir mines, near Barroteran. Mining equipment will be put in consisting of machine drills, hoists and a concentrating plant. The number of men at work will he increased to 300. It is reported that the Mexican Central will build a spur from its San Pedro–Paredon branch to the mines. The ores are silver-lead-zinc.

GUANAJUATO.

J. H. Hohhs et al., of Colorado Springs, Colo., are reported preparing to put up a 100-ton mill at La Luz mine, near Guanajuato.

SAN LUIS POTOSI.

T. C. Creeling, manager of the Tiro mines, near Las Charcas, says he is making arrangements to build a narrow-gauge railroad from the mines to Las Charcas station on the National railroad.

SONORA.

At Emperor camp, near Magdalena, the Loraine M. Co. has completed an addition of five stamps to its mili and is running ten stamps. Last week a shipment of twelve kilos was made. The Loraine is owned hy Tener Bros. & Balch.——The Magdalena M. & E. Co. has been organized to develop and operate a group of mines in the Cibuta mountains, 4 miles west of the Sonora Railway, near Cerro Blanco. There are two veins of high-grade gold ore, on which some development has heen done. The officers are A. N. Carter, W. Schuckman and F. F. Hummel.

The Latz & Pearce group at Puertocitos is reported sold to the Lake Superior G. M. & M. Co. for $100,000 gold. The group adjoins a portion of the Greene Con. M. Co.'s properties.

Three groups of gold prospects near the Picacho mine, 35 miles southwest of Cos, have been bonded by R. K. Clancey of Detroit, Mich., the Eva for $250,000, the Cinco Senores for $90,000 and the Don Ramon, Adan and Dos Amigos for $20,000. These mines are owned hy Douglas, Ariz , men.

The Nogales C. Co., among other improvements which it is starting at its properties near Magdalena, will put up a 100-stamp mill; and a concentrator and 40-ton smelting plant are being erected at La Blanca mines, near Suaqui Grande. The Santa Cruz C. Co. has been organized to work a group at Santa Cruz. The Gutierrez M. Co., working the Gutierrez mine at La Barranca, has taken under lease and bond for $75,000, gold, the Belene mines of La Barranca, and the Nahuila group at San Javier for $65,000, gold, and development work will be started at both places. An American company has hought of the Lopez Bros. of Hermosillo some gold properties near Acouchi for $100,000, gold, and the Carmen and Esmeralda, both of Arizpe, have also heen hought by an American company at $40,000 and $100,000, gold, respectively. Near Bocoachi W. Lane reports a gold strike, says the Investor.

ZACATECAS.

There is considerahle activity reported in the State of Zacatecas, in the way of railroad building to the mining sections, principally to Somhrerete and Mazapil. The Comacho M. Co. is building a hranch road from Comacho station, on the Mexican Central, to Mazapil, a distance of 20 miles, and another line is projected from the National to Mazapil; and still another from Mazapil to Concepcion del Oro, a distance of 30 miles.

NOVA SCOTIA.

D. B. Richardson of Toronto, of the Dominion Coal Co., says the area of coal land extends for a distance of 45 miles from Sydney to Louishurg, and five collieries are working, raising 11,000 tons of coal a day. Increased development work is being done.

SIAM.

A new mining district is reported attracting attention. Rubies have heen found at Klong Aeng, in the Amphur district of Sri-Buathong, Muang Krat, in the Monthon of Chantaburi. Some forty persons were digging and washing for precious stones there, and evidently making a living at it at least. A formal notification has been issued bringing the district under the mining Act, and from August 1 every miner will be required to have a permit, for which he will pay 5 ticals a year, says the Times of Burma.

SIBERIA.

L. Tovey, mining engineer, of Tomsk, says the iron industry is not the only industry which is making progress iu Siberia. Extensive placer claims which have heen operated in a primitive way for 100 years are being equipped with machinery and considerahle work is being done in sinking shafts and tunneling to cut the veins of gold and silver ores which are found in the northern districts.

TASMANIA.

The Mt. Lyell M. & R. Co., at Mt. Lyell, report for month of July shows: From June 25 to July 22, inclusive, a total of 16,971 tons of ore was treated; average assay value of ore hefore treatment was: Copper, 2.14%; silver, 2 33 ounces; gold, .088 ounce per ton. The converters produced during same period 573 tons of blister copper, containing: Copper, 567 tons; silver, 49,698 ounces; gold, 1722 ounces. In addition to the ahove, there were treated during same period 981 tons of Mt. Lyell ore and metal-bearing fluxes. The reduced quantity of Mt. Lyell ore treated was due to weather conditions, having entirely suspended operations in open cuts four days during period and accident to smelting works.

Catalogues Received.

"Appliances for Assayers" is a catalogue with an illuminated cover from the Calkins Co., 608 N. Main street, Los Angeles, Cal., describing their latest improved Calkins' assayers special appliances, including assay furnaces, hydrocarbon burner, cupel press, ore crusher, zinc shavings, etc.

The Cyclone Drilling Machine Co , Orrville, Ohio, sends a catalogue of their drilling machinery, including the hollow rod system, with full detailed illustrated information concerning their several makes. There is a wide field for their use, including prospecting of gold dredger ground, and the subjects are of interest.

Catalogue No. 54, Victor Turbines, is at hand from the Stilwell–Bierce & Smith–Valle Co., Dayton, Ohio, Pacific coast office, 11 First St., San Francisco, Cal.—leather hound and of vest-pocket size, containing "power tables of Victor turbines, comprising the cylinder gate, register gate and high pressure types," and accompanied hy numerous illustrations.

Of standard size (6x9 inches), substantially bound and superhly illustrated, the new drill catalogue No. 43 of the Ingersoll-Sergeant Drill Co., 26 Cortlandt street, New York City, commends itself to the attention of mining men. This fine volume of 168 pages is stated to be the first of a series of catalogues which will illustrate and describe in complete form all classes of Ingersoll–Sergeant machinery. The one to hand sets a high standard of excellence, and one that will doubtless be maintained.

Of standard size, 6x9 inches, Catalogue No. 11, fifth edition, from the Allis-Chalmers Co , Chicago, U. S. A., treats of the Tremain steam stamp, with full illustrated description, and practical instructions for erecting the Tremain mill. In addition minute details of instruction are given, including ninety separate engravings of as many parts of the Tremain steam mill. There are also complete estimates of each requirement in setting up and operating a Tremain steam stamp mill. The treatise is in sumptuous style from the press of the Meisenheimer Printing Co., Milwaukee, Wis.

PERSONAL.

J. RODMAN, Leadville, Colo., is in New York City.

G. M. HARRIS has returned to New York from Alma, Colo.

W. E. DUNCAN is in San Francisco, Cal., from Oroville, Cal.

D. W. BRUNTON has returned from Montana to Denver, Colo.

H. V. WINCHELL has returned from a visit to Copper River, Alaska.

E. F. JONES of Oroville, Cal., is in San Francisco, Cal., on mining business.

L. A. GROSS, an Amador county, Cal., mine manager, is in San Francisco, Cal.

A. J. SELFRIDGE, of Boston, Mass., is in San Francisco, Cal., on mining business.

R. B. CROWELL of Tonopah, Nev., is in San Francisco, Cal., on mining business.

H. K. WHEELER, M. E., of Los Angeles, Cal., is visiting San Francisco, Cal

W. H. CLARY, a Calaveras county mine owner, near Murphy, is in San Francisco, Cal.

J. FULLERTON, interested in mines at Red Lodge, Mont., is in San Francisco, Cal.

JAMES EARLS is superintendent of the Bullion–Beck mine, Eureka, Juah county, Utah.

J. ERISMAN, manager of the Blue Flag M. Co., at Cripple Creek, Colo., is in Buffalo, N. Y.

S. NEWHOUSE has left Salt Lake City, Utah, for a several weeks' visit at Bar Harhor, Me.

S. NICHOLSON, manager of the A. M. W. Mining Co., Leadville, Colo., is in Nova Scotia.

J. F. MCFARLAND of Grand Junction, Colo., is at Alma, Colo., looking after mining interests.

CHAS. M. FASSETT has returned to Spokane, Wash., from a visit to San Francisco, Cal.

D. MCCLURE, superintendent of the Gwin mine, Calaveras Co , Cal., is in San Francisco, Cal.

G. E. ALEXANDER, E. M., of Denver, Colo , is in California, investigating the mining industry.

R. M. GREEN, a mine owner of Oroville, Butte county, Cal., is in San Francisco, Cal., on business.

W. H. KINNON, metallurgist, is superintendent at the Majestic C. Co. smelter, at Milford, Utah.

H. HUCKINS is superintendent of the Junction mine, near North San Juan, Nevada county, Cal.

N. GETCHELL is superintendent of the Post group, at Grantville, near Berlin, Nye county, Nev.

P. A. H. FRANKLIN returned to Salt Lake City, Utah, last week, from a two months' trip East.

ARTHUR HAUMAN has been appointed United States Deputy Mineral Surveyor at Jamestown, Cal.

J. SHINN, Leadville, Colorado, has been examining mining property near Grant, Park county, Colo.

A. D. MCLAIN is superintendent of the Trapper's Pride mine, near Marysvale, Piute county, Utah.

H. P GORDON has returned from San Francisco, Cal., to his mine superintendency at Nashville, Cal.

J. F. HOLDEN of the Corona G. M. Co , near Prescott, Ariz., has gone to Chicago, Ill., on mining business.

G. W. KEEL is superintendent of the Little Bell and the Lucky Bill Mining Cos., at Park City, Utah.

G. ASHTON has returned to Pueblo, Colo., from Summit Co., Colo., where he has been examining mines.

J. L. SHEPARD, president of the Tri-Metallic M. & S. Co., has returned to Nogales, Ariz , from a trip East.

W. E. THORNE has returned to San Francisco, Cal., from an investigation of mines in Siskiyou county, Cal.

GUIDO DE VOLTAIRE is consulting engineer for the Jupiter M. Co., operating at El Oro, in the State of Mexico.

I. HALE, manager of the Denver branch, General Electric Co., has returned to Denver, Colo., from Summit Co., Colo.

E. C. VOORHIES of Sutter Creek, Cal., has been appointed manager of the Darien Mining Co. at Cana, Colombia.

GEORGE F. SHURTLEFF, general manager of the Crowned King Mines Co , Crown King, Ariz , is in New York.

JOHN SPARKS, principal owner of the Wedekind and Desert King mines near Reno, Nev., is in San Francisco, Cal.

TODD C. WOODWORTH, formerly of California, is now consulting engineer of the Sibley–Sawyer Co. of Boston, Mass.

F W. BRADLEY, president Bunker Hill & Sullivan M. Co , has returned from Wardner, Idaho, to San Francisco, Cal.

L. W. VAUGHN of Merced, Cal., president of the Stockton Con. C. M. Co., is at the company's mines in Shasta county, Cal.

W. N. LINDSEY, E AND R A. HATTON of Red River, Taos county, N. M , have gone to Idaho to look after mining interests.

T. W. JAYCOX, Leadville, Colo , has been appointed Deputy State Engineer of Colorado with headquarters in Denver, Colo.

F. COBB, with Taylor & Brunton of Denver, has returned there from Dillon, Colo., where he was inspecting mining property.

J D. MURPHY bas resigned as superintendent at the Bullion–Beck mine, at Eureka, Utah, and has gone to Salt Lake City, Utah.

W. W. MEIN, mine manager for the Durban-Roodepoort Deep, Ltd., near Johannesburg, South Africa, is visiting in Oakland, Cal.

E. A. HERPSBERGER of Almagordo, N. M., has gone to Jarilla, Otero county, N. M , to superintend operations at the Garnett mine.

D. R. MORGAN, mine manager of the Torreon smelter, at Torreon, Chihuahua, Mexico, has estahlished his headquarters at Chihuahua.

MANAGER G. D. B TURNER of the J. I. C. mine of Park City, Utah, returned last week to Salt Lake City, Utah, from a trip to Scotland.

A. R. BOYNTON of the McKinnon G. M. Co., operating at Silver City, Idaho, returned to Cbicago, Ill , last week from a trip to their mines.

L. HEYNEMAN, secretary of the Fulton Engineering & Shipbuilding Works, has returned to San Francisco, Cal., from an Eastern business trip.

J. A. MCSHANE of Omaha, Neb., owner of the Belen, Refugio and other mines at Ocampa, Chihuahua, Mexico, has returned from a visit to his mines.

A. A. ROSS, formerly with the Southern Nevada M. Co., at Searchlight, Nev , is superintendent of the Empire Con. M. Co., operating in same section.

H. M. GORHAM, superintendent of the Chollar, Virginia, Nev., is at Colegrove, Cal. A. J. McDonald has charge at the Chollar in Mr. Gorham's absence.

GEO. W. CAMPBELL, of Oakland, Cal., of the firm of Scott, Dow & Co., owners of the Black Oak mine at Soulsbyville, Cal., has heen appointed general manager.

W. F. SNYDER, president of the Western Ex. Co , has returned to Salt Lake City, Utah, after several weeks at the

Balaklala copper mines in Shasta county, Cal.

G. McM. Ross has resigned as superintendent of the Ophir M. Co., operating at Virginia City, Nev., and is superintendent of the Andes, also on the Comstock lode.

M. L Requa, vice-president of the Pacific Wire & Steel Works and a mine owner of Nevada and California, leaves the coming week for a trip through the East.

H. W. Fairbanks, geologist, has returned to Berkeley, Cal, from an extended tour of northern California gathering material for a series of school textbooks.

A. C. Lawson, professor of geology and mineralogy, University of California, has returned to Berkeley, Cal., from a geological tour of the southern Sierra Nevada mountains.

Jesse Scobey has resigned as general manager of the Pride of the West M. & M. Co, and will he in Denver, Colo , after Sept. 1, where he will he engaged as consulting mining engineer.

J. R. Ryan has resigned as superintendent of the Andes S. M. Co., at Virginia City, Nev., and is superintendent of the Con. Cal. & Virginia and Ophir mines, which have been consolidated.

Commercial Paragraphs.

Fraser & Chalmers, Ltd, of 43 Threadneedle St., London, E. C., England, state that on the 11th inst. their offices were removed to 3 London Wall Buildings, London, E. C.

The Compressed Air Machinery Co. of San Francisco, Cal., is preparing for shipment a Word drill sharpener to the St. John del Rey mine in Brazil, via Rio Janeiro. They shipped one last week to the Daly-Judge mine at Park City, Utah

The Risdon Iron Works, San Francisco, Cal., report during the last week having received an order from J. H. Leggett of Oroville, Cal , for one of their largest sized gold dredgers, costing $80,000. This company built a dredger operating on Mr. Leggett's ground about two years ago, and they report that Mr. Leggett is so well satisfied with its gold saving properties that he has adopted this type of machine and will use it on his ground in the future.

"On the 15th of July," writes the Penberthy I jector Co. of Detroit, Mich., "we placed the number 300,000 on one of our 'Penberthy' automatic injectors, having completed this number of injectors in just a little over sixteen years, a remarkable record, especially when it took nearly ten years to convince engineers that an automatic injector was a practical device, and to manufacture and sell the first 100,000 machines. Three hundred thousand injectors is a good many. Basing figures on the average capacity of the injectors sold during the past twelve months, the 300,000 'Penberthy' automatic injectors on the market will handle in one hour 109,500,000 gallons of water. This amount of water if pumped into an upright tank 50 feet square would require the tank to be over a mile high; or, to put it in another way, if the output of these 300,000 injectors were combined into one stream, they would supply a river 10 feet deep and 250 wide, and keep up a steady flow of water at the rate of a little over 1 mile per hour. If the 300,000 injectors were all connected to one source of water supply, they would in ten hours completely drain a lake 10 feet deep, 1 mile long and ½ mile wide." Information regarding these injectors will be gladly furnished any inquirer by the Penberthy Injector Co., Detroit, Mich.

Obituary.

Pedro Alvarado, known as a wealthy mine owner and philanthropist of Parral, Chihuahua, Mexico, died on the 18th inst. He was owner of the Palmillo mine at Parral.

W. E. Dodge, of the firm of Phelps, Dodge & Co., and a large holder in the Copper Queen mine, at Bisbee, Ariz., died at New York on the 9th inst. Deceased had passed his seventy-third year.

H. F. Kemper, one of the original locators of the Temple Bar placer mines in Mohave county, Ariz , died in Kingman, Ariz., August 11, after an illness of several weeks. Deceased was born in Ohio forty-one years ago, and is survived by a wife and several brothers.

New Patents.

Dewey, Strong & Co.'s Scientific Press Patent Agency, 330 Market St., S. F., has official reports of the following U. S. patents issued to Pacific coast inventors:

FOR WEEK ENDING AUGUST 11, 1903.

735,851. — Therapeutical Apparatus — G. L. Abell, Oakland, Cal.

735,689.—Strap Lock—W. P. C. Adams, Seattle, Wash.

736,191.—Draft Equalizer—F. Bahler, Spokane, Wash.

735,933.—Timber Framing Macrine — Barnes & Smith, Pearce, Ariz.

736,061.—Cetyl-gnaiacyl — M. W. Beylik, Burhank, Cal

736,202.—Cork Retainer—W. E. Brown, Los Angeles, Cal.

736,203.—Heater—G. W. Brunner, S. F.

735,942.—Ore Crusher — A. C. Calkins, Los Angeles, Cal.

735,862.—Clutch—P. F. Dundon, S. F.

736,078.—Treatment of Ores—H. T. Durant, London, England.

735,863.—Engine Cylinders — Duryea & White, Los Angeles, Cal.

735 957.—Animal Trap—G. F. Eherhard, S. F.

735,865.—Portable Desk—J. B. Elliott, S. F.

735,734.—Wrench—C. C. English, S. F.

735,868.—Saw Sharpeners—G. A. W. and J. H. L. Folkers, S. F.

735,872.—Sash Lock—L. H. Handy, S F.

735,972.—Hotel Reoister - C. H. Harger, S. F.

735,979.—Weighing Machine—G. Hepner, S F.

736,100.—Locator—N. Hosiettler, Eugene, Or.

736,098.—Purifying Liquors—J. Houden, S. F.

735,733.—Ticket Holder—A. L. J. hnson, Seattle, Wash.

736,267.—Well Drill — H. Kelly, Los Angeles, Cal.

735,986.—Vineyard Cultivator — I. B. Kilgore, Concord, Cal

735,886.—Cultivator—G. P. Kimhall, Salem, Or.

735,887.—Powder Distributor—G. Lagomarsino, S. F.

736,121.—Boot Calk — A. P. Lipscomh, Yaeger, Cal.

736,123.—Rail Joint—P. J. Lukes, Balls Ferry, Cal.

735,991.—Train Pipe Coupling—J. C. Martin, Jr., S. F.

735,997.—Igniter for Gas Engines—J. D. McFarland, Jr., S. F.

736,136.—Piston Rod Joint—J. D. McFarland, Jr., S. F.

736,137. — Propeller — A. C. G. H. McIntosh, Eureka, Cal.

735,794.—Fastening—C. E. Morgan, Portland, Or.

735,994.—Fish Cleaning Machine — T. Morris, S. F.

736,140.—Memorizer—Mary E. Nicholl, Oakland, Cal.

736,334.—Curtain Fixture—Susan A. Norwood, Portland, Or.

735,897.—Logoing Jack—J. G. Owen, Southhend, Wash.

736,006.—Electric Railway—J. W. Perkins, San Jose, Cal.

735,813.—Ore Separator — Pira & Salomonson, Oakland, Cal.

736,305.—Amusement Device—A. Seyfried, S. F.

735,843.—Corset—Nettie Temple, Stockton, Cal.

735,919.—Quicksilver Furnace - A. A. Tregidgo, S. F.

736,320.—Weed Cutter—J C Walter, Athena, Or.

736,325.—Feed Mechanism—White & Duryea, Los Angeles, Cal.

Notice of Recent Patents.

Among the patents recently obtained through Dewey, Strong & Co.'s Scientific Press U. S. and Foreign Patent Agency, the following are worthy of special mention:

Piston Rod Joints.—No. 736,136. Aug. 11, 1903. J. D. McFarland, Jr., Fruitvale, Cal. One-half assigned to J. Bruckman of San Francisco, Cal. This invention relates to improvements in means for connecting the piston rods with a crank shaft, and is particularly applicable in engines having a plurality of radially disposed cylinders in the same plane. Its object is to confine the connections between the piston rods and crank shafts within the narrowest practical limits and to provide for take up when these bearing parts have become worn.

Vineyard or Orchard Cultivator.—No. 735,986. Aug. 11, 1903. Ira B. Kilgore, Concord, Cal. The object of this invention is to provide a cultivator which can he driven between rows of growing vines, trees or like objects so as to thoroughly cultivate the soil between the rows, and to so construct the device that the angle of the cultivating teeth to the line of travel may he changed, so as to throw the soil to or from the rows between which the apparatus is traveling, and also to change the forward and backward tilt of the teeth that they may he more or less upright with relation to the line of travel.

Hotel Reoister.—No. 735,972 Aug. 11, 1903. C. H. Harger, San Francisco, Cal. This invention relates to improvements in registering devices in which there is a containing box or case, a series of loose leaves, and a transversely and longitudinally lined supporting plate for the leaves. Its object is to provide a perpetual register for hotel purposes which shall he simple, neat and compact, and which shall permit of the introduction of additional leaves when necessary and of the removal of leaves when they have become filled.

Device for Sharpening Saws.—No. 735,888. Aug. 11, 1903. G. A. W. Folkers and John H. L. Folkers of San Francisco, Cal. This invention relates to improvements in saw filing and sharpening machines of the type employing rotary cutters or grinders. Its objects are in the direction of simplicity of construction and of securing steadiness and uniformity in operation of the file members in relation to the saw.

Apparatus for the Treatment of Ores With Solvents.—No. 736,078, Aug. 11, 1903. H. T. Durant, London, England. This invention consists of a peculiarly constructed tank and means for circulating the solution through the tailings or like contents of the said tank. The object of the invention is to provide an apparatus for the treatment of various ores, tailings or the like hy the use of solvents which are suitable for the particular character of the ore under treatment and hy the use of which solvents the gold and silver or other metals may he extracted.

Animal Traps.—No. 735,957. Aug. 11, 1903. G. F. Eherhard, San Francisco, Cal. Assigned to the Geo. F. Eherhard Co. of San Francisco, Cal., a corporation. This trap is designed particularly for gophers and other hurrowing pests. The object of the invention is to obviate the disadvantage present in ordinary traps of this general type hy forming these jaws so that hy no amount of wriggling can a gopher once in the grasp of the jaws escape.

Latest Market Reports.

San Francisco, August 21, 1903.

METALS.

SILVER.—Per oz., Troy: London, 25⅞d (standard ounce, 925 fine); New York, bar silver, 54¼c, refined (1000 fine); San Francisco, 54¼c; Mexican dollars, 42½c San Francisco, 42c New York.

COPPER. — New York: Standard, $13.75; Lake, 1 to 3 casks, $13 62½@13 75; Electrolytic, 1 to 3 casks, $13.62½@13 75; Casting, 1 to 3 casks, $13.25; San Francisco: $13.00. Mill copper plates, $17.00; bars, 18@24c. London: £59 10s spot per ton.

In his report to the United States Geological Survey on the production of copper in 1902, C. Kirchhoff says the copper mining industry of the United States suffered during 1902 from the reaction which followed the unsuccessful attempt during 1901 to maintain the value of the metal at an artificial level. The collapse which came toward the close of 1901 left many producers committed to sales covering a long period, at low prices, with the menace of heavy accumulations of metal constantly over the market. Yet production was heavier during 1902 than it had been in 1901, because some of the important mines were worked to full capacity and because some of the enlargements and improvements previously hegun became effective during the year. Furthermore, a number of new enterprises first produced important quantities of metal. On the other hand, labor troubles cut down the output of some of the larger undertakings.

As compared with 268,782 long tons in 1901, the total production of copper in the United States in 1902 was 294,423 long tons, of which the Lake Superior district produced 76,165, or 25 9%; Montana, 128,975 long tons, 43 8%; and Arizona, 53,547 long tons, 18.2%. This is an increase in the total production of 25,641 long tons, or nearly 10%, as compared with 1901.

The imports of copper ore in 1902 were valued at $7,921,641, as compared with $14,394,663 in 1901; and the imports of copper in bars, ingots, pigs and in manufactured forms were valued at $12,864,021, as compared with $11,820,459 in 1901. The exports of domestic copper in different forms were valued at $46,811,729 in 1902, as compared with $36,071,448 in 1901. The exports from Baltimore, Md., increased from 54,377,355 pounds in 1901 to 103,607,256 pounds in 1902; and from New York the increase was from 133,540,150 pounds in 1901 to 236,622,515 pounds in 1902.

In the aggregate the reporting mines had a stock of 155,665,652 pounds of copper on January 1, 1903, as compared with 282,014,297 pounds on January 1, 1902, a decline of over 126,000,000 pounds during 1902.

The estimated consumption in 1902 was 551,688,191 pounds, as compared with 382,761,014 pounds in 1901. The average selling price of Lake copper during 1902 was 11.86 cents per pound.

LEAD.—New York, $4.25; Salt Lake City, $3.50; St. Louis, $4.00; San Francisco $4.50, carload lots; 4¼c 1000 to 4000 lbs.; pipe 5½, sheet 6, bar 5½c; pig, $4.75. London: £11 6s 3d per long ton=2.75c per lb.

SPELTER. — New York, $5.87½; St. Louis, $4.85; London, £20 12s 6d per ton; San Francisco, ton lots, 6½c; 100-lb lots, 7c.

ANTIMONY.—New York, Cookson's 9¾c; Hallett's, 8½c; San Francisco, 1000-lb. lots, 7½c; 300 to 500 lbs., 7½c; 100-lb. lots, 10c.

SITUATIONS WANTED.

EXPERT DIAMOND DRILL FOREMAN AND Setter of twenty years' experience in various parts of the world. At present employed, but desires change and a permanent position in the West. Can hring one or two operators as desired. Address "Diamond," this office.

MINE SUPERINTENDENT WANTS POSITION with a substantial company that hae a mill on property. A qualified mining engineer who can run a mine or mill, cyanide plant, assaying and eurveying. Address "Mining," this office.

MINING ENGINEER NOW IN CHARGE COPper proposition desires change of location. Management gold or copper proposition. State terms Address Box 25, this office.

MINING ENGINEER AND METALLURGIST, at present general manager of a large mining concern in Mexico, desires to change his position. Would need four months' notice. Address F.B.A.S., care of this office.

MINING ENGINEER WISHES POSITION AS superintendent or assistant superintendent at metal mine. Has had eight years' experience in civil and mining engineering, and is surveyor, draughtsman and assayer. Also had practical experience in underground work and handling men. Can furnish transit and two sets halances Age twenty-eight. References. Address Box 818, Salt Lake City, Utah.

MINING ENGINEER, GRADUATE GERMAN University, at present assistant manager of gold mining corporation and in charge of large amalgamating, concentrating and cyanlding mill, desires change. Thorough experience in treatment of refractory gold ores hy all processes. Would like position as manager or assistant manager of producing company. Age 33; unmarried. Best references. Addre.s R. R. 18, care of Mining and Scientific Press

POSITION BY PRACTICAL MINING ENGIneer; 20 years' experience in U. S., Alaska and Mexico. Reference Al. Specialty, commercial mining. Address W., care of this office.

WANTED—A POSITION AS MANAGER OF quartz mine; 20 years' practical experience. Would take charge of a prom'sing, undeveloped property, and could invest some money in it. First-class references. Address "Reno," care of Mining and Scientific Press.

YOUNG GRADUATE WITH SOME EXPERIence in Assaying, Surveying and Draughting, wants position in mine. Salary not so much an object as advancement. Address H.N., this office.

WANTED.

Wanted, 1 First-Class Amalgamator for 20-Stamp Mill.

Wages $4 per day. Board $5.75 per week. Address, giving references,
CHELAN MINING CO.,
BLEWETT, WASH

WANTED—A First-Class Assayer and Chemist,

with extended cyanide experience, for position of Assayer and Chemist with large gold mining company, with cyanide plant. Must have best of references. State age, experience and salary wanted. Address "Chemist," care of Mining and Scientific Press.

WANTED TO SELL This Machinery, Cheap.

Six-Drill Compressor; Double Cylinder Hoist, good for 800 feet; Large Double Reel Geared Hoist, good for 1500 feet; 60 H. P. Fire-box Boiler. All in good condition. Address "Machinery," this office.

Whole No. 2249.—VOLUME LXXXVII. Number 9. SAN FRANCISCO, CAL., SATURDAY, AUGUST 29, 1903. THREE DOLLARS PER ANNUM. Single Copies, Ten Cents.

IN the notices of catalogues which appear weekly in another part of this journal considerable stress is laid from time to time on the fact that certain of those received are of "standard" size, meaning that they are 6 inches wide and 9 inches long, that being the standard some time ago adopted as being in the judgment of many the most suitable and convenient size. While of course there is nothing compulsory or obligatory as to what size anything shall be, yet in the case of a trade catalogue it is well that some convenient size should be adhered to as closely as possible, and the size specified is probably as convenient a general size as any that could be suggested. The main idea in those catalogues is preservation; when they vary so much in size it is impossible to conveniently file them, and thus some of their usefulness is lost. Many leading firms will spend from $5000 to $15,000 on a single catalogue, and they are veritable works of art. The old term "catalogue" is a misnomer; they are rare trade treatises, often sumptuous in their typographical excellence and admirable in illustration and style, and of high value as a technical treatise, up-to-date on the subject of discussion, and finely showing the "present state of the art" as regards points discussed. Often these elaborate trade treatises contain much better material than more pretentious bound volumes on technical subjects, and deserve a place in the library of the progressive man. That they may have such permanent place is why the "standard" size is advocated.

The Yellow Aster Mine and Mill, Randsburg, Cal. (See Page 132.)

THREE months ago was made modest announcement herein of the entrance of this journal on its 44th year of successful existence. Immediately came cordial words from nearby friends and patrons; later were received similar congratulations from more distant well-wishers, and like a stone dropped into water the widening rings of motion reach remote shores from which come congratulatory echoes months after the little notice of the 43rd milestone having been passed. Fortunate indeed is the publication that is able to justly earn so cordial and widespread expression of good wishes, and its aim and earnest effort shall be to deserve their continuance.

THERE is always intimate connection between the prosperity of the country and the condition of the mining industry. When mining is prosperous so is the country, and vice versa. Most particularly is this manifest in the case of gold and silver. The reason is plain. Money, which is the blood of business, is based, so far as redemption is concerned, on gold and silver. If it were not for the regular output of these metals the present prosperity of the country could not continue: when the mining industry languishes, every other industry languishes likewise. This is why mining is justly styled the basic industry. The unparalleled prosperity of this country during the past six years is proportional with the flourishing condition of the mining industry in that time. Should its life wane, so also would the life of every other industrial enterprise. Hence it is that they who would recklessly end the present era of industrial prosperity by making it unwise or unprofitable to commence or continue mining operations are in the same position as the man who sawed off the limb of the tree on which he sat. This seems to be a department in which human experience of the most disastrous kind counts for nothing. Men have to learn the same sad lesson of the centuries, each generation by itself, in ignorance or defiance of the eternal and inexorable law of cause and effect.

TO get the best of "strikes" some industry will eventually organize a trust in which employer and employe (capital and labor) will combine to cinch the consumer. In that way the employer can pay any wage demanded, and still keep going, simply passing the raise up to the consumer. This is most possible in a skilled industry. If the consumers don't like it they can organize a trust of their own. The situation is not devoid of humor.

A National Necessity.

Much has been said in this journal in the last ten years in favor of the creation of a cabinet department of mines and mining, and the arguments advanced in supporting such a measure continue to gain in force by the natural sequence of events. The objection is noted that, as the supervision of the mining industry can well be left to the several States, it is unnecessary to burden the general government with such a matter.

But that is only begging the question. The point asserted as conceded is one of the things denied by the supporters of the project. The supervision and fostering care required by the nation's greatest basic industry is justly a national question, and can be best served by national aid. There are many things that the several sovereignties which make up this great republic can do, but there are many things that none but the national government can compass with justice to all, and this is one of them. The federal power is dominant over all, and when it lays the great ægis of its supreme authority over any subject, that takes on a majesty and is lifted to a lofty height of industrial importance denied to any thing controlled solely by State laws. If the mining industry of the United States were confined to a few insignificant sections of our common country; if the interests it represents were of little commercial importance, or if its destinies had little influence on our national life; if it mattered little whether the mining industry lived or languished, and if the issues involved affected only a small part of the people, the objection might have some weight. But as all the other industries of the continent rest upon the mining industry; as its operations are coextensive with the extent of American territory itself; as it is only the federal power that can wield the necessary national influence to administer on such a necessary national industry, it is only business that requisite attention be bestowed upon such industry by the creation of a national bureau that can alone give the needed attention which through the years has been withheld.

The question cannot be downed nor put aside; it may some day become a political question, just as have other matters of less import in our national life. Originally when we were weak and small the Federal Cabinet had but four members. As we advanced, the President's advisers grew in number with the growth of the country. Many things needed fostering care and protection, and they rightly got it. The mining industry never asked for any help. It asks none now. In peace or war it has ever held up the arms of the nation and with sturdy independence has made possible the splendid progress that has marked the years and made this a world-wide power. The fact that the nation occupies the forefront rank is due to the mining industry as much as to any other one factor in so splendid and satisfactory a result. Nor does there come any Macedonian cry for help or succor from any miner anywhere. As a private proposition the mining industry of the nation and the several States will advance in proportion to the wealth they develop and the skill, vim and science of those who make up the mining world, with due regard to the limitations imposed by the nation's neglect. It is not a plea for assistance nor a bid for office that prompts the suggestion that a cabinet department of mines and mining is needed. It comes from a clear conception of national requirements; from a knowledge that such a department is needed as a public measure; the evidence that however efficient State supervision may be, it lacks the iron-clad potency of federal jurisdiction; it comes from the consciousness in the minds of many that the great industry that has furnished so great a part of our national wealth should have the attention that will enable it to be of even still greater good to the nation of the twentieth century. What mining has done for the nation is but an index of what it can do. As a business proposition it would be the best paying investment the nation ever made to create a national department of mines and mining and have a representative of the nation's greatest industry in the President's cabinet. The matter is not a narrow one of place or petty politics; it is one of wide import and should be treated in a broad gauge way. It should be the province and the purpose of our public men to conserve the interests of their country, and where duty and policy so plainly dictate the way it should not be difficult to follow it.

"HOPE springs eternal in the human breast," and so does folly, the latter being fostered by fooling the credulous. Profitable extraction of gold from sea water, oil of gold, transmutation of silver, etc., into gold are constantly kept before those who take stock in that sort of thing. Occasionally the game is varied. A Leadville, Colo., genius takes a half-page advertisement to give all and sundry short cuts to fortune. By the simple process of exercising his faculties as a "prophetic seer and psychic" he can guarantee to anyone fortunate enough to be possessed of a dollar how to succeed in stocks or actual mining operations. Those who buy mining stock worth most for wall paper purposes and subsequently write asking an opinion regarding its unworth, might well advise with him. They couldn't do worse. It is questionable, however, whether the "seer and psychic" can be of much avail to the miner. True, he claims in his advertisement where upon payment of $1 he fell into a "trance" and falling out thereof located "nine valuable gold and copper claims in Gunnison county." True, also, according to the advertisement, that he similarly rediscovered "lost ore shoots" in Cripple Creek; yet it is, after all, unlikely that he will continue to content himself with a paltry dollar fee for putting others in position to acquire rapid wealth when he can see those veins of gold in the ground, and, doubtless, we shall all presently hear that he has discarded such slow process of accumulating riches and gone into finding rich store of gold in place for himself.

A Splendid Result.

The decadence of the once famous mining town of Virginia, Nev., calls to mind the debt that mining owes to the methods pursued by the miners of the Comstock and their splendid audacity in the days when it took nerve to do what they did, viz.: prove the existence at depth of ore in greater paying quantities than surface or superficial workings would warrant. Like the cautious voyagers of ancient days, who crept carefully from headland to headland, ever content to skirt the shores of the great sea, many miners of an earlier day had mostly confined their workings to be continuous only with the continuity of ore, and when a "barren zone" was encountered work usually stopped in that particular place. If the oxidized ore gave out and the sulphurets came in; if water made sinking a matter of expense, or the small appropriation made further progress a question of doubtful finance, the tendency was to stop and try elsewhere. But as Columbus, sublime in the conception of scientific fact, forsook the shore and sailed boldly out to discover a new world, so the Comstock miner discarded ancient custom and regardless of precedent or tradition went on in demonstration of the fact that a superficial stratum of hard rock, or an apparently insuperable obstacle of water or swelling ground, only made necessary the exercise of greater enterprise and skill. The material success that crowned his efforts, that poured a steady stream of treasure into the nation's life at the very time the nation was engaged in a struggle for existence and most needed help, great as that success was, is but a part of the advantage the world derived in the splendid lesson taught, that in mining, as in other things, the greater the obstacle the greater the incentive to overcome it. It is largely because of his indomitable courage and energy that deep mining is now possible in every place where now successfully carried on, for when men saw the vast treasure uncovered at Mount Davidson, the sight told them that in many other places the same energy would tend to the same success.

Nevada has other Comstocks probably equal in value to the Comstock of a generation ago, and is now busy uncovering some of those embryo bonanzas. That great mining State has had its day of decadence, but will have its day of assured success, when its output of bullion will approximate that of the early '70s.

How curiously things come about is illustrated in the case of the Comstock, for it is but fair to say in any reference to this matter that it was the purchasing public that largely enabled the miners of the Comstock to go ahead on so great a scale. The tremendous expenditure in those days of enormous cost was made possible by the lavish supply of funds. For those were the days when every one with a few dollars to spare bought stocks in the Comstock, and the companies operating there had unlimited funds at their disposal. At that day the ordinary private company operating in California or Nevada or Colorado had to keep a close watch on the expense account, and often when the ore secured in sinking a hundred feet failed to yield sufficient profit to pay for the sinking of another hundred feet, it became a question whether that next 100 feet would be sunk or not. In the case of the Comstock captains they were not thus hampered. The purchasing public mostly knew little and cared less whether the mine shaft was down 300 or 3000 feet, or whether the breast of the drift on the lowest level was in ore or not. What they were watching was the ticker on the stock exchange, for the street was worked then as diligently as the mine, and while the purchase of stocks made an ever-flowing treasury and the managers had unlimited funds at their disposal, the temporary owners of the stock usually held them only long enough to "make a winning." Thus the gamble was at the bottom of it all; but this does not detract from the skill of the men who seized the opportunity to do some of the biggest things in mining ever heard of, nor does it affect the permanent value to the mining world in the demonstrated results. The copper miner in Michigan, Montana and Arizona, the gold miner in South Africa, Australia, Colorado and California, the lead miner in Missouri, Idaho or British Columbia, is to-day doing bigger work with better results because of what the miners of the Comstock did so many years ago.

CONCENTRATES.

AS THE term "amorpbous" means not formed by crystallization, it can not be correctly applied to any alloy.

AS THE ash of charcoal is strongly alkaline, it would be of use as a flux in tho case of ore reduction referred to.

A SOLUTION of cyanide out of which all oxygen has been removed is not capable of dissolving any gold or silver out of their ores.

WHENEVER steel works are established on the Pacific coast the manganese oro deposits will be of commercial value, but are not thus available at present.

LAST YEAR'S world's coal production was about 920,000,000 short tons, of which the United States produced 33%, the United Kingdom 30% and Germany 20%.

NINE PARTS of lead, two parts of antimony and one part of bismuth make an alloy that will expand when cooling, this being of practical value in filling holes in castings.

ACETYLENE GAS has a specific gravity of 13, referring to hydrogen as a unit, or of 0.92, if air is taken as the unit. The ordinary specific gravity of illuminating gas is about 0.5.

IN the care of electric machinery cleanliness includes dryness, for wet and dirt often go together. Of course there is much apparatus that has to work out of doors and is designed accordingly.

NO ATTENTION is to be paid to those compounds "fuel stimulants," advertised as having great power to increase the heating value of coal. They are "fakes," solely designed to swindle the investor.

OPAL consists of hydrous silica, the proportion of water varying from 2% to 13% in different varieties. The mineral is softer than quartz, hardness from 5 to 6, quartz being 7. Its specific gravity ranges from 1.9 to 2.3.

TO HARDEN STEEL in the case of ordinary makes, it must be heated above a temperature of 700° C. Salt water conducts heat better than pure water; the salt assists in keeping the surface of the steel clear of scale, and therefore aids in the hardening.

A CENTRIFUGAL PUMP with an 8-inch suction pipe and a 6-inch discharge, running at 600 revolutions per minute, lifting water 42 feet, with a fall of 12 feet in the suction pipe leading to the pump, would have a theoretical capacity of 2650 gallons per minute.

MICA for electrical purposes must be free from oxides of iron and other foreign substances. The best for that purpose comes from India. Deposits in New Hampshire and North Carolina are also in the market and are largely used, as are deposits from other States for commutator work.

A SIMPLE chemical test will distinguish between sylvanite and calaverite. Boil the mineral with concentrated nitric acid. The decanted solution when diluted and tested with hydrochloric acid gives a curdy precipitate if sylvanite; very little precipitate, or merely a turbidity, if calaverite.

IN round numbers the value of the gold mined or produced in the United States in the last calendar year was $88,000,000; the number of ounces of silver mined in the same time was 67,000,000; copper production, 300,000 long tons; tons of lead produced, 268,000,000; tons of zinc produced, 160,000,000.

STREAM TIN has been recently reported in southwestern Colorado, but not authoritatively. There is no doubt as to the discovery of stream tin on Buhner creek, near Cape Prince of Wales, Alaska, but not in commercial quantity, the matter being so far more of a curiosity than a profitable proposition.

THE contractor is merely a pieceworker on a larger scale. As he is paid by the job, it is to his interest to turn out his work as quickly as possible and to get as much work as he can from the men working for him. The system insures quantity. To insure quality requires rigid inspection and the holding of everybody to strict account.

THE staggering headache caused by giant powder smoke can be immediately relieved by tablets prepared especially for such use. If those prepared tablets can not be had, a combination of acetanilide, citrated caffeine, soda bromide and gelsemium will afford instant relief, but that combination should be prepared by a competent doctor or druggist.

THE recalescent point in forging steel is that at which the change of cooling rate takes place and when begins a change in the structure of the steel. The fluid steel begins to crystallize at the point of solidification. If the steel be heated slightly above the recalescent point when allowed to cool it will be found that the crystallization is much smaller than before.

CONCENTRATED BLENDE in carload lots from the Rob Roy mine at Joplin, Mo., has assayed as high as 65.46% zinc. Pure zinc sulphide contains 67.15% zinc. The Rob Roy concentrates' yield illustrates the high grade of the ore and the degree of efficiency in the work of concentrating. Lead and cadmium alloy with zinc, but iron does not make a true alloy.

VERY little dynamite is now made in which there is any free nitro-glycerine. In nearly all instances manufacturers now gelatinate the nitro-glycerine with soluble gun-cotton, and this jelly, and not nitro-glycerine, is mixed with the wood meal and nitrate of sodium. Picric acid is made from nitrating carbolic acid. It is worth from 22 cents to 26 cents per pound.

IT is not infrequent for commercial litharge and red lead to contain a trace of gold and noticeable quantities of silver. The best brands, however, contain no gold and but the slightest trace of silver. Pure granulated lead and lead foil are always available for assayers' use. The average loss of gold in crucible assays may be estimated to be about .3%, and of silver about 2.5%.

LAND may be taken up for a mill site or as a mill site, in connection with a lode claim, and held by use for purposes directly connected with mining even though it is not used as a mill site, the requirement being that it be used by the owner or locator for milling or mining uses. The five acres may thus be used as a boarding house for those employed in the mine or mill, or for ore bins, etc.

A POND of water the surface of which has an area of 765,000 square feet would be discharged through a conduit 15 feet below its surface, 15 inches in diameter and 50 feet in length, in ninety-two hours, fifty-four minutes and ten seconds. A pipe with a diameter of 9 inches, a length of 4750 feet, and under a head of 17.5 feet, will discharge, theoretically, 69.67 cubic feet water per minute.

IN one of the latest processes for the electro-metallurgical production of zinc, the ground ore is passed into a bath of molten zinc chloride, which acts on the silver and lead sulphides. Chlorine is then passed through and acts upon the zinc sulphide, converting it into chloride. The chlorides of lead, silver and other metals are thus produced, and the metals can be fractionally electrolyzed out.

IN riveted joints for steam boilers there is a possibility that the joint may fail by shearing the plate between the first row of rivets and the edge of the plate, especially if the first row is the only one put in. To insure proper strength at that point, the rivets should be set back from the edge of the plate far enough to provide at least as much metal as the rivet contains, and, if slightly more, so much the better.

AN approximate rule for determining the diameter of rivets is to extract the square root of the thickness of plate and multiply it by 1.25. The actual diameter of rivet may be varied slightly from the results secured by this rule in order to use standard sizes. For illustration, take a plate .5 inch thick, the square root of which is .71. Then .71 multiplied by 1.25 equals .8875 inch. The nearest standard size is ⅞-inch, which would be used in such a case.

THE legal responsibility of the Idaho labor union is a matter that can not be disposed of in a "concentrate." The question is still one of energetic legal discussion. There can be no serious wrong without a corresponding legal remedy, and wherever there is great power there must be an equal degree of responsibility. In the case cited, however, the question would seem to turn upon the point as to whether an unincorporated union could sue or be sued.

IT IS difficult to correctly assure accuracy in the fire assay for lead. In the volumetric methods the ferrocyanide and molybdate methods are considered quick and accurate. The ferrocyanide is best performed with a 1% solution of potassium ferrocyanide. The solution to be titrated should be about 100 c. c. in volume, should contain 10 c. c. of 50% acetic acid, and should be at temperature of about 60° C. The correction for indicator is about 0.8 c. c.

CARBIDE OF IRON contains three atoms of iron to one of carbon and occurs in all steel of ordinary use. In metallurgy it is called cementite. There is about 0.8% carbon in ordinary commercial steel and about 0.89% in pure carbon steel. The most commonly accepted theory of how the addition of carbon to iron creates the alloy known as steel, is that by getting between the iron crystals it stiffens the whole mass up, thus producing the great increase of strength.

STEEL is coming into favor in some localities for shaft lining. The question is entirely an economic one. Whichever costs less is the best, the question of "cost" to be considered in all its bearings. In this regard too much attention can not be justly given to statistics that do not take all the facts into consideration. Nothing is more misleading than statistical information when one or two important factors are omitted. Both steel and wood have their places in shaft lining, and local surroundings determine which is the cheapest. In the case from whence comes the inquiry (northern Montana), timber would undoubtedly be the cheaper.

TO COMPUTE the form of an irregular body weigh it in and out of fresh water, and note the difference in pounds: then as 62.5 (the weight of a cubic foot of fresh water) is to this difference, so is 1728 (the number of inches in a cubic foot) to the number of cubic inches in the body. Or, divide the difference in pounds by 62.5, and the quotient will give the volume in cubic feet. Thus if the irregular-shaped body weighs fifteen pounds in water and thirty out, it has a volume of 414.72 cubic inches.

ELECTRICAL POWER has attained its highest development, so far as transmission is concerned, in the western part of America. In Colorado, Utah and California are some notable long distance electric transmissions. In the latter State as a successful paying proposition sixty thousand volts are transmissible over 200 miles. In Mexico the Guanajuato Power & Electric Co.'s line now in process of completion is 105 miles long, and will work at 60,000 volts three-phase. In this latter instance it is designed to minimize the possibility of insular weakness by using steel towers and long spans of conductor between supports.

IN parting with nitric or sulphuric acid the gold almost invariably retains a small percentage of silver. Because of this the weight of gold resultant is usually a little more than it actually ought to be, and that of silver a little less. When nitric acid is used for parting, the error is partly balanced or even transposed in character by the solution of a little gold, the latter case generally occurring when the proportion of silver to gold is large. With ordinary work the possible error is very slight and the matter is of consequence only in the assay of bullion. Ordinarily the silver retained by the gold after parting will not amount to more than .3%. In bullion assays the parted gold will retain, as a general thing, about .1% or less of silver. The exact amount of error in any case can be determined by check assays with pure gold and silver.

THE weight of a cubic foot of compressed air at 85 pounds at 70° F. equals .58 pound. Nothing but the best grade of air cylinder oil should be used for lubricating air cylinders. Cheap or poor grades contain light unsuitable oils which will volatilize at high temperatures, especially in the case of simple compression to 100 pounds. Such oils also contain residue, which collects around the valve or in the discharge passages, and interferes with the proper operation of the compressor. Where oils are used which volatilize easily the gas formed collects in the discharge pipe and receiver, and when mixed with the air coming from the cylinder and contained in the receiver forms an explosive mixture under pressure and at a temperature which requires only a slight increase to cause spontaneous ignition, and a possibly serious explosion might thus result. The cylinder lubricators should always be closed the moment the compressor is shut down to prevent oil accumulating in the cylinder.

REFINING silver containing small amounts of gold and other impurities is now a common commercial proposition. Only the gold residues reach the mint. The scarcity of silver deposits at those government institutions is to the employes a serious inconvenience, since the usual acid refining methods require a large amount of that metal as parting material in treating the gold bullion received. The great mass of mint gold deposits contain some silver and are usually too impure for either coinage or industrial use without refining. Some contain platinum, which is lost in the usual wet processes. It has been the mint practice to alloy the gold in the deposits with two and one-third times its weight of silver, and subject this mixture to the action of nitric or sulphuric acid. In consequence of the very limited deposits of silver, it is necessary to use the same silver repeatedly as parting material, at a great expense for acid. If two and one-half times as much impure silver as of gold came to the U. S. mints, the parting process would not be so wasteful.

IT IS a necessary part of mining development in the long run that a United States patent be procured for the ground. It constitutes the only sure title, and in the case of a proposed sale the purchaser will consider the question of title next in importance only to the possible value and extent of the ore. True, it costs a good deal; costs more than it should, but it is of iron-clad potency and is a deterrent to litigation. In case of a stock company instances are not wanting where with every intent to be honest those in charge while spending considerable money in requisite development omitted to secure a patent, and when the money ran out and trouble came, the ground finally became subject to relocation, with the result that the innocent stockholders lost the property. It should be borne in mind that no matter if the ground has been steadily worked for twenty years, no matter how much in the way of improvements may be thereon, a failure to put a paltry $100 worth of annual improvement during any of the required time may cause the ground to revert to the government under the letter of the law, and thus be subject to relocation.

Some Structural Features of the California Gold Belt.

NUMBER II.

Written for the MINING AND SCIENTIFIC PRESS by W. H. STORMS.

It is a noticeable feature of the lode that the principal fissures occur generally along a gulch or valley. Where this is the exception, the rocks forming the country adjacent to the lode have generally been protected from erosion by ancient river channels, overlain by a heavy deposit of volcanic material, the general course of which is across the lode. At Jackson a valley half a mile or more in width runs parallel with the lode for nearly 2 miles. On the east side of the valley the dolomitic vein reappears with all of its usual features, and, like the greater part of the lode elsewhere, is low grade in gold. On the west side and along the bottom of the valley the fissures are largely in black clay slate or partly at contact with the slates and amphibolite schist. In the Kennedy and Argonaut mines, which are the most extensively developed in Jackson district, the vein occupies the plane of a reverse fault in its upper portion, but in the lower levels it splits up and large masses of gold-bearing quartz are formed in the amphibolite schist. In the Kennedy mine, on the 2100 level, a somewhat anomalous occurrence is noticed in the formation of a large vein in the foot wall diabase. This vein strikes approximately with the main fissure, but dips easterly and southerly at 0° to 30°, and at one place has a slight west dip, the dip of the main fissure varying from 60° to 70° below the 800-foot level, being somewhat flatter above. In some of the lower levels of the Kennedy and Argonaut mines veins of solid quartz occur 25 to 30 feet in width. Usually several feet of the foot wall portion—7 to 10 feet—are high-grade ore and the balance is low grade. The foot wall portion is usually banded. In these mines the structure of the veins, as influenced by the rock in which they occur, is particularly noticeable, though, generally speaking, similar conditions produce like results elsewhere. In those portions of the vein occurring in slate, the vein is usually banded and forms that type of vein structure known to miners as "ribbon rock." Often in these veins the movement of the walls has been communicated to the vein itself, and polished faces within the vein, due to these movements, are not uncommon. Where one wall is composed of slate and the other of amphibolite schist, the slaty side of the vein usually develops the banded structure, the schist side showing a more massive condition, with usually more or less of the schist included in the vein. A sharp line of demarkation usually distinguishes the separation of these two types of structure, with the smooth, polished faces of quartz at the line of junction. This structural condition suggests that the mineralization has extended outward from a single fissure or crack, the slate being gradually silicified on one side and the schist similarly altered on the other. The heavy, putty-like gouges which nearly always accompany the veins of this portion of the lode seem to have been formed almost entirely by movement subsequent to the formation of the vein. This is evidenced by the occurrence within the gouge of fractured pieces of vein quartz, ground up and broken pieces of iron sulphide and other conditions which clearly indicate that these fissures have been planes of movement during a long period, both prior to vein formation and subsequent thereto. In some instances well-formed veins are found crushed and brecciated and recemented by silica. These often include black fragments of slate or schist and give to the ore a peculiar spotted appearance. For this character of rock the miners have various local names —"bull quartz," "boulder quartz" and "magpie" are the names most commonly heard. This character of rock is usually low grade and often worthless. It often occurs in large masses up to 150 feet in thickness. It occurs to a greater or less extent throughout the lode, and elsewhere in California, and may be ascribed to similar conditions as to structure and movement of surrounding rocks wherever found.

Northward from the Argonaut and Kennedy mines the vein passes beneath an ancient river channel, reappearing a few thousand feet northward at the Oneida mine. Here the lode is practically reduced to a singe fissure in the slates. The mine is developed to a depth of 2200 feet and exhibits the usual characteristics, just described, as being representative of the Kennedy. Northward of the Oneida mine, the lode again is buried beneath an ancient channel, and is found beyond in the South Eureka mine. It should be understood, however, that the vein is here continuous throughout, and that the mine workings extend for thousands of feet beneath the old river channels.

In the South Eureka mine the vein is much shifted and contorted, and faults—called by the miners crossheads—are numerous, rendering the mine difficult to work and expensive to keep open. All of the mines in this portion of the lode in black slate walls have heavy, swelling ground, and the expense incident to keeping up this kind of ground is almost equal to the first cost of opening the mine workings, owing to the mining methods in general use, and if the workings are required to be kept open for long periods, the cost greatly exceeds the original expense of cutting and timbering a drift or other workings. The method of making all permanent excavations, such as shafts and the main gangways in the wall rocks, at a distance from the vein sufficient to avoid the swelling ground, has been repeatedly suggested, but with few exceptions has not been put into actual practice; but these isolated exceptions readily prove the advantage that this system of mining would afford. This applies with emphatic force to the large three-compartment shafts, which, when sunk in the fissures, prove to be very expensive to maintain. Rapid winding through such shafts is extremely dangerous, if not impossible, owing to shifting of the position of shaft timbers. All such shafts are sunk on an incline usually approximating 63°. Several deep vertical shafts have been sunk within the past few years to depths of 2000 to 2700 feet. The most noted of these are the Oneida, down 2200 feet, which cut the vein at 1900 feet, and the Kennedy, down nearly 2700 feet, which is calculated to reach the vein at about 3500 feet.

These shafts are sunk through the hanging wall country through diabase, amphibolite schist and black slate. The Argonaut, some years since, sunk an inclined shaft in the hanging wall schists, and passed through the fissure at about 450 feet, again cutting the vein below the 1000-foot level, the vein having taken a steeper pitch, while the shaft was maintained at a uniform angle of 63°. These shafts, expensive in first cost, have proven already far cheaper than any of the shafts sunk on the vein fissure, for the reasons above given.

From the north end of the South Eureka southward, on the divide between Jackson and Sutter Creek, the fissure system, as previously explained, consists of a number of approximately parallel veins; but in the Central Eureka, joining the South Eureka on the north, and in the Badger and Eureka, which lie immediately north of the Central Eureka, the vein system is reduced, as far as development has gone, to practically a simple fissure, with a few small branches which extend into the hanging wall.

The black slates which accompany the main fissures for a distance of nearly 3 miles, with greatly varying width, and often split up by the intrusive diabase, and, possibly, by faulting, into several separate tongues of slate, are here not over 100 feet wide.

The Central Eureka mine is developed to a depth of over 2000 feet through an inclined shaft. The vein varies from 4 or 5 feet to 20 feet or more in thickness, with lenses of quartz ore from a few inches to large masses nearly filling the fissure. The fissure is more simple than in any of the several mines above described, and may be considered an ideal vein in this respect. The quartz is partly banded and partly massive, as in the other mines of the vicinity.

North of the Central Eureka, the Amador Consolidated (Badger and Eureka), which has been idle for thirty or more years, is worked to a depth of about 2100 feet and has a record of producing $18,000,000. It is said to be geologically similar to the Central Eureka—a simple fissure vein, though of greatly varying width. The Wolverine, at Sutter Creek, adjoins the Eureka, and was developed to a depth of 1000 feet with extensive levels, but it never proved largely profitable. This fissure extends uninterruptedly northward, so far as known, into the Wildman mine, in the town of Sutter Creek, and in its southern portion it is supposed to maintain the character developed in the Eureka and Central mines; but in the south end of the Mahoney mine the vein splits, one branch extending northerly through the Mahoney or Hector mine into the Belmont, and the other, the west branch, runs through the southern portion of the Mahoney into the Lincoln mine.

The northern end of the Wildman and southern part of the Mahoney are greatly disturbed by faults and flextures down as far as the 1200 level of the former, at least. (See Fig. 1.) This is particularly interesting in view of the fact that for a mile to the southward (to the north end of the South Eureka mine), the fissure is comparatively undisturbed. The ore bodies of the Wildman-Mahoney lie between two reefs of black slate, though these slates do not come in direct contact with the ore bodies. The splitting of the fissure into two distinct veins in the Mahoney is not duplicated, as far as known, on any other portion of the gold belt, for the two branches do not reunite. There are numerous instances southward where the veins split and in a greater or less distance are reunited, but such is not the case here.

(TO BE CONTINUED.)

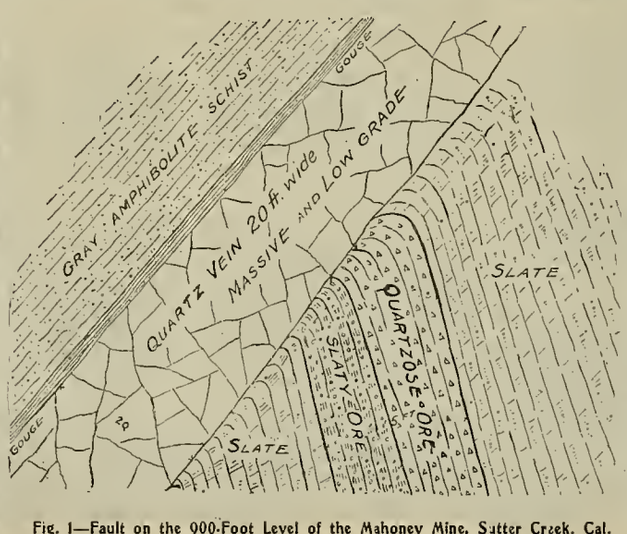

Fig. 1—Fault on the 900-Foot Level of the Mahoney Mine, Sutter Creek, Cal.

Parting Gold and Silver Bullion.

There are three methods of parting gold and silver: The nitric acid, the sulphuric acid, and the electrolytic process, respectively. The latter is well adapted to large smelting works. The nitric acid process is the oldest. It is thoroughly satisfactory, but the comparatively high price of nitric acid and the necessity of using either platinum or porcelain vessels has led to its being superseded in many modern refineries by the sulphuric acid parting process. Diluted sulphuric acid has no action on silver, but the strong acid, when heated, is decomposed by that metal, giving off sulphurous acid and forming silver oxide, which passes into solution in the excess of acid as silver sulphate. If gold is present in percentage, not to exceed one-third of the whole, strong sulphuric acid will extract the silver and leave the gold as a granular brown sediment. Should the bullion contain one-half gold, the latter metal will protect the silver against acid attack, and the result will be failure. It is the business of the refiner to adjust for the melting pot gold deposits with those of silver carrying small quantities of gold, or to add fine silver so as to have from two to three parts of silver for each part of gold. Such an admixture is melted in a large crucible, thoroughly mixed, and then with a dipping cup, is poured into cold water. Most bullion contains varying quantities of copper, and this metal works very badly in strong sulphuric acid. While decomposing the acid with formation of copper sulphate, the latter, unlike the silver sulphate, is insoluble in oil of vitriol, hence, if present in any considerable quantity, copper soon acts as a protector to the bullion and the chemical action either ceases or becomes tediously slow. Besides apportioning the silver to gold, it is necessary, therefore, to so combine deposits that the granulations do not contain more than 6% to 8% of copper. The success of this process really depends upon the fact that while weak sulphuric acid rapidly dissolves iron, yet, if the acid be strong enough, it has no appreciable action—just the reverse of its relations to silver. Cast iron vessels may, therefore, be employed. Large iron kettles are used, weighing half a ton, mounted over a furnace. Into this a charge of 300 to 400 pounds of granulated bullion is placed, and covered with three or four times its weight of acid—66 B. Heat is applied, when a lively evolution of sulphurous acid sets in, which, if too violent, must be checked by the addition of a little cold acid and slackening of the fire. This boiling is continued for several hours, during which time the escaping and consumed acids are gradually replaced. When the solution is complete the fire is withdrawn and the contents of the kettle allowed to quietly settle. A little cold acid is added to aid the precipitation of any suspended gold. Hoods over the kettles carry off the fumes to condensing and suppression apparatus. The strongly acid solution, while still hot, is siphoned off into the reducing houses. These are long, rectangular vats lined with lead, and provided with sloping covers. Slabs or ingots of metallic copper are placed on the bottom and sides of these vats, which are then partly filled with cold water. The hot silver solution is then run in, with resultant crackling and spluttering. The result is a weak solution of silver sulphate, rendered milky by the separation of fine crystals of that salt, the soluhility of which is very slight in pure water. The copper immediately begins to precipitate the silver as a crystalline mass, easily detachable from the plates when the operation is complete. This requires about twenty-four hours. Meanwhile the copper has taken the place of silver, leaving a strong solution of copper sulphate (blue vitriol). This blue solution is drawn off for crystallization, and the spongy silver carefully transferred to leaching tubs for thorough sweetening with fresh water. The silver, now in the form of minute, flaky crystals, is compacted into cakes by means of hydraulic pressure and these cakes dried in a current of warm water, after which a simple fusion in a black-lead crucible without fluxes gives a bullion 0.998 or 0.999 fine. If silenium or tellurium is present in the bullion, it will pass into solution with the silver and he deposited with it by the copper plates. In this case the spongy

silver will be dark colored and the melt will he brittle. It must then be fluxed with niter. The sulphate of copper is then carefully prepared for the market, the proceeds thus materially reducing the expense.

Electrolytic Leaching of Copper Ore.

A low-grade copper ore can he leached; the commercial results may not he wholly satisfactory. If there are large quantities of ore and one has money, he may make a commercial success. The process itself does not offer many great difficulties. The copper must he transformed into a sulphate, if water is to he had cheap enough. If sulphuric acid can be used, a simple oxidizing roasting will hring the copper to a condition where it will dissolve in diluted sulphuric acid. If the copper in the ore is a carhonate, the roasting, of course, can he omitted in the acid leaching. It is a common practice in such case to pile the ore, allowing the rain and air to oxidize the copper sulphides, forming copper sulphate, which water will extract from the ores; hut this is a very tedious process, involving a long wait for returns.

The ore carrying a little gold and copper can be leached with a hot solution of cupric chloride in a rotating harrel, through which a slow alternating current of electricity is passed. This cupric chloride solution is prepared with a saturated solution of calcium or magnesium, chloride or salt, so that the combined chemical and electrical action extracts all the copper from the ore. The clear solution is run through a harrel containing copper oxides or hydrates, which will remove all the iron and similar impurities from the solution, leaving in it only pure copper. This solution is then passed into rectangular vats containing porous ashestos partitions with electrodes for conveying the current to the solution as it passes in the vats. As the copper is deposited the solution is pumped back to a reservoir for further use, this being made to last indefinitely, a little water heing added to make up for evaporation and a little chemical to supply losses by leakage. The ore being freed from copper is then in condition for cyaniding. So far as known, however, the above described process has not been tried on a scale that would entitle it to endorsement from a commercial standpoint. Carhonate copper ore can be leached with sulphuric acid and deposition by electrolysis.

A generator of 100 amperes, through a series of 320 vats or plates, will, theoretically, deposit 2000 pounds of copper per twenty-four hours from a sulphate solution, and nearly 4000 pounds from chloride solution. The per cent of hluestone is proportionate to the increase or decrease of surface; with 8% it would he 10 feet. Where sulphate is used and insoluhle anodes, lead or carhon would do for the anodes. The vats in such case should he small, so that the slimes deposited from aeration of the solution could he easily cleaned out without disturhing too much of the series. A convenient size would be 4 feet square on each end and from 5 to 8 feet in length if a simple series is used, or 15 feet if tandem series; anodes 36x40, or with common series can be composed of smaller pieces. With such plate service the generator should have ahout 125 voltage.

The Cripple Creek Drainage Tunnel.

Written for the MINING AND SCIENTIFIC PRESS.

The more extensive development of Cripple Creek mines has heen greatly retarded in some sections by encountering heavy flows of water, which in some instances was greater than the pumping plants were ahle to handle, though of great capacity. As an outcome of this condition, the expedient, which had been successful elsewhere, that of driving a drainage tunnel, was suggested and finally undertaken hy the El Paso Mining Company of Beacon Hill under the direction of William Bainbridge, manager and superintendent of the El Paso mine. A. C. Jaquith is the engineer in charge of the enterprise. The sum of $80,000 was suhscribed by the several companies whose interests were directly affected hy the success of the enterprise. The suhscribers were as follows:

Frank F. Castello, for the Mary McKinney Co.	$15,000
J. Arthur Connell, for the Work M. & M. Co.	1,500
J. R. McKinnie, for the Moon-Anchor Co.	1,500
F. J. Campbell, for the Anaconda Co.	4 000
Irving Howhert, for the Anchoria-Leland Co.	2,500
Sherwood Aldrich, for the Elkton G. M. Co.	15,000
Horace Granfield, for the C., K & N. Co.	3,500
Sam S. Bernard, for the El Paso Co.	25,000
Frank G. Peck, for the Midget Co.	1,500
A. E. Carlton, for the Doctor-Jack Pot Co.	5,000
Midland Terminal and F. & C. C. Railway	2,500
Taylor & Brunton, sampler	1,000
C. M. MacNelll, for U. S. Reduction & Refining Co.	2,500
Total	$80,500

This subscription was equal to the estimated cost. Work was hegun on the tunnel Jan. 25, 1903, the entrance heing near the confluence of Cripple Creek and Arequa gulch, north of Grouse mountain.

The level of the drainage tunnel is 250 feet helow the Standard tunnel. An idea of the relative position of these tunnels may be gained by referring to the accompanying sketch. (Fig. 1.) The hlack line at the hase shows the line of the tunnel, the unfinished portion of which at the time of the beginning of the recent strike is indicated by the cross.

Prior to the beginning of the tunnel, an estimate was made for the Elkton Co. of the amount of coming water in the Elkton and other mines of the vicinity, with a view to determining the advisahility of continuing pumping operations. Investigations were made covering a period of several weeks, and these showed that the quantity of water varied from a minimum of 40,000,000 gallons to 170,000,000 gallons daily, and it was concluded that it would be far cheaper to drive a long drainage tunnel than to undertake to drain the area by pumping to the depth the tunnel could reach.

With the exception of the small uncompleted section which remained a few days ago, the tunnel is in ahout 5230 feet, which includes that portion of the El Paso workings on the line of the tunnel. The accompanying sketch map (Fig. 2) of the several properties through which the tunnel passes, shows the direction of its alignment. A large amount of work has been accomplished from the El Paso shaft, and two other shafts were sunk on the tunnel line to facilitate the work. These are shown in the vertical section. If the tunnel be continued under Raven and Globe hills, its length will exceed 12,000 feet, or ahout 2½ miles, without counting lateral hranches.

Upon the success of this enterprise depends the driving of a second drainage tunnel at a lower level. Shou'd this latter project he undertaken, it will douhtless be well under way hefore the reserves made availahle hy the present tunnel are worked out.

The first tunnel to drain the mines of the district to a marked extent was the Moffat, driven into Gold hill. The amount of water flowing from this tunnel reached as high as 3000 gallons per minute. The Standard tunnel was driven about 200 feet lower, which completely drained the Moffat tunnel. The present tunnel, driven in the common interest of all the mines of that vicinity, is called the Cripple Creek drainage tunnel. The site for a second syndicate tunnel has not yet been selected.

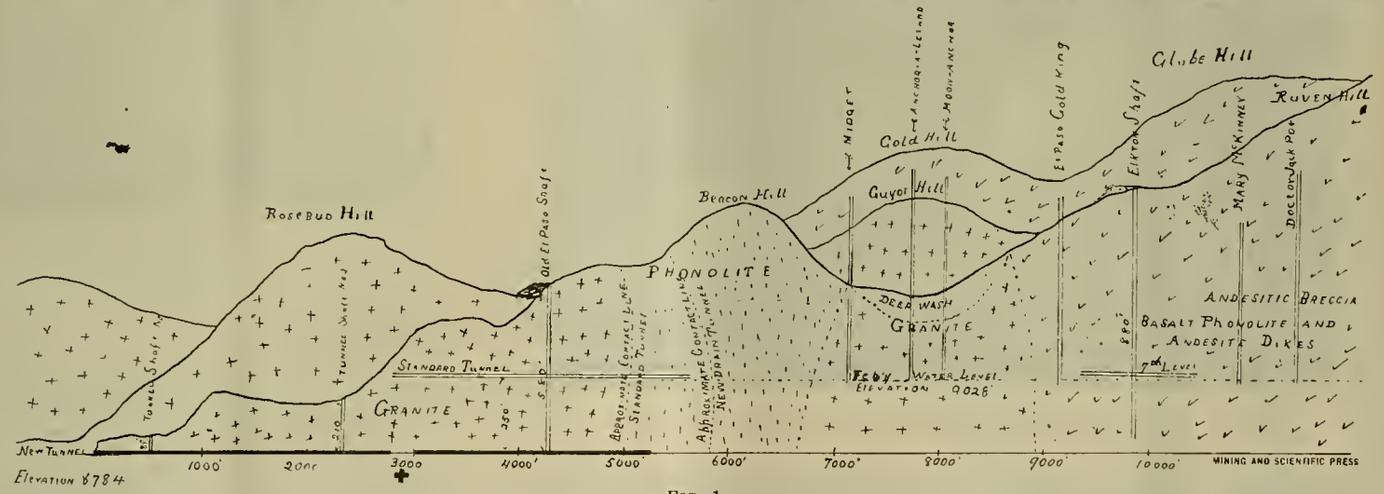

FIG. 1.

Production of Platinum in 1902.

The report for 1902 to the United States Geological Survey on the production of platinum in 1902 is now in press. The report is in two parts—the first heing the report proper, by Dr. Joseph Struthers, and the second heing a paper hy Prof. J. F. Kemp on platinum in the Rambler mine, Wyoming.

The production of platinum from domestic ores in the United States decreased from 1408 ounces, valued at $27,526, in 1901—the largest output recorded hy the Geological Survey since 1880—to 94 ounces, valued at $1814—the smallest production since 1893. In connection with the platinum, there were also ohtained from the ores 20 fine ounces of iridium, as against 253 ounces in 1901. The domestic supply of platinum in recent years has been ohtained as a secondary product chiefly from gold placer deposits in Trinity and Shasta counties, Cal. It is reported that the metal occurs, though not in commercially rich deposits, in many other gold placers of California, as well as in Washington, Oregon, Idaho, Montana, Colorado and Alaska. The Rambler mine, Wyoming, continues to attract attention, and during the year, a considerable quantity of the metal was collected, hut not marketed, hy the Waratah Minerals Co. at Kerhy, near Grants Pass, Josephine county, Oregon.

The Russian sources of platinum supply, which furnish about 90% of the total consumption of the world, are comparatively limited. The platinum-hearing ores extend along the eastern watershed of the Ural mountains in Eastern Perm and along the watershed farther south.

The imports of platinum into the United States during 1902 were valued at $1,987,980 as compared with $1,695,895 in 1901.

SELIUM is the latest metal discovered. E. Mollard, a Frenchman, reports its discovery hy him, and claims that it will cost only one-twelfth as much as aluminum; that it is lighter and stronger than that metal. The further claims that it is rustless would indicate its value for mine, ship and railway work.

FIG. 2.

Mining Aqueducts.

The ditch and flume of the hydraulic miner is finely supplemented in many cases by preparatory work of great magnitude and expense, carrying immense volume of water through unusually large pipes over hills and across valleys at a difference in height sometimes as high as 400 feet. In several Colorado, California and Idaho enterprises 48-inch pipe, thousands of feet in length, is in use.

To some of these mining aqueducts the term "inverted siphon" is applied. The first contrivance of the kind to which that name was applied is believed to have been that put in by the Spring Valley Mining Co., at Cherokee, Butte county, Cal., in 1871, a wrought iron, riveted, 30-inch pipe, 14,000 feet long, across a depression of about 950 feet. The structure was described in the MINING AND SCIENTIFIC PRESS at the time. Since then the size and make of the pipe has been considerably changed, the pipe being often now made with an expansion joint, and at times being 48 inches in diameter.

The term "inverted siphon" is not technically correct, as these aqueducts do not work on the principle of the siphon. Their mission is to utilize the pressure of the water at the inlet to maintain a regular, steady flow, forcing the water of the outlet branch or arm of a V-shaped pipe line out at a point slightly below the level of the inlet, thus carrying water at great head and enormous pressure across rivers, under roads, and up and down steep bluffs to where it is needed for hydraulic mining. It is not uncommon to thus spend $300,000 or $400,000 in preparatory work.

The accompanying engravings show how water is

Flume and Hydraulic Work, Boise River, Idaho.

Carrying Water in a 48-Inch Pipe, 1700 Feet Long, Over Boise River, Idaho.

thus conveyed in an "inverted siphon" in an Idaho hydraulic mine, Boise river; the upper picture shows where the water is brought from Sheep creek, across the Boise river, that part of the pipe being 1700 feet in length and 48 inches in diameter. The lower engraving shows the flume and ditch work in the latter part of the system, where the water finally reaches its work on the gold gravel deposits.

A NEW ALLOY for bearings subjected to heavy loads, such as those of railway axles, is described by G. H. Clamer as consisting of 64 parts of copper, 5 of tin, 30 of lead and 1 of nickel. The metal casts well and is easily worked. Its large proportion of lead greatly reduces wear, and when used as a bearing for a journal 3¾ inches in diameter by 3½ long, run at 525 revolutions per minute and loaded to 1000 pounds per square inch, the loss in weight was but a fifth of a grain in 100,000 revolutions. Under the same conditions, the wear of gunmetal of varying proportions of copper and tin was from 2½ to 4 grains.

Sulphide Treatment.

In the Carmichael-Bradford process gypsum is dehydrated—turned into what is really plaster of Paris—then well mixed with sulphide concentrates (or slimes), the percentage of gypsum used being about 20%. Water is added, and when the mixture is thorough it is set out to dry, crushed small to an average size of 1½ to ¾ inch. The dust is sieved out and set aside to be again mixed. After being crushed the mass is ready for the converter; size, 3 feet 9 inches across top, 3 feet 1 inch deep, V-shaped, bottom plate well covered with red-hot coal, of equal redness all over, to a depth of 2 inches. The pot is filled with the rough mixture—the rougher at the bottom and the finest on top—a hood is placed on the top and 1½ ounce of air turned on. After a quarter of an hour the air current is increased to 2½ to 3 ounces, which is kept going until the pot is cooked. The pot used in recent experiments contained 12 cwts., average time occupied in a thorough cooking 1½ to 2 hours. Slimes take no longer than concentrates. The gist of the process is in the use of the gypsum, the knowledge of the percentage necessary and the proportional sizes of the machinery necessary for the charges. The machinery is simple—a converter and a blower, the latter part of the ordinary type in every-day use. The air is conveyed into the converter from the bottom. If the process is used on a large scale, various mechanical devices will be adopted for saving time and labor in respect of charging, tipping, cleaning, and so on. The product is a rough, homogeneous mass. The difficulties stated to be overcome are incomplete desulphurization, loss of metals by volatilization and the fine condition of metals to be fed to the blast furnaces.

The process may prove valuable in the treatment of zinc. Further value may be derived in distilling sulphuric acid, as the sulphur from the pots can be liquefied and turned into the acid.

A Test for Gold and Silver.

To test quartz for the presence of both gold and silver by the use of nitric or muriatic acid, the ore should be reduced to a powder sufficiently fine to pass through a No. 60 sieve. Place this pulp, when screened, in some flat iron vessel over a fire, so as to burn out those elements which readily sublime or burn. The pulp, when cool, should be placed in a glass vessel and covered with nitric acid, pure or slightly diluted with water. To facilitate the action of the acid, the vessel containing the acid and pulp should be set in a pan partially filled with sand; then heat the pan. The sand will prevent the glass vessel from bursting by rapid expansion. As soon as the acid begins to boil set it off the fire and let remain standing for several hours. Add about as much again water as there is acid and pulp, then shake or stir thoroughly and filter off the liquid. The liquid thus obtained is a solution of the nitrates of all the metals that the rock contained and that are soluble in nitric acid. Add drop by drop a strong solution of common salt. If a white precipitate appears after adding the salt, it is either oxychloride of bismuth, mercurous chloride (calomel, a salt of quicksilver), or chloride of silver. To tell to which of these three classes the salt belongs, pour off the fluid above; if it dissolves it is bismuth, and neither silver nor quicksilver. If it does not dissolve pour off the acid and to the precipitate add strong ammonia. If the precipitate dissolves the salt, it is silver chloride. If it does not dissolve, it is quicksilver chloride or calomel. To the dried silver chloride add an equal amount of washing soda or borax, then it can be melted to a "button" of bullion.

As to the gold, take the pulp and filter saved from the first part of the experiment and put into a crucible and heat. The filter will completely burn. Next put the pulp through a very fine screen. Now soak for two days in an acid consisting of a mixure of four parts nitric and fifteen parts muriatic acid, which has been prepared at least two weeks before. This will convert any gold present into a perchloride of gold. Platinum will also be converted into a perchloride. Again filter; take the liquid that filters through and evaporate to dryness, either in a porcelain dish or glass flask in the sand, as before decribed. This is done to remove the acid. Dissolve the dry residue in water, simply by adding warm water to the flask as soon as it is sufficiently cool not to burst when adding the water. When the salt which remained in the flask after evaporating is thoroughly dissolved again, add a solution of ferrous sulphate (copperas) or of oxalic acid and set aside. Let stand for two or three days. A fine brown powder precipitated to the bottom of the flask is pure powdered gold. Pour off the liquid above the powder, wash thoroughly and dry. These precipitates may be melted into a gold "button," but it requires great heat.

The following is a simple test for gold which may fill ordinary requirements so far as gold is concerned: For gold in oxidized ores, pulverize the sample and place in a porcelain-lined vessel or tea cup, cover with iodine and allow it to stand for two or three hours. Then dip into it a piece of white filter paper, dry and burn it, and if it gives a purple color gold is present, and the deeper the purple the richer the ore. For other ores with this test, such as pyrites, the ore must be roasted. Where lime is present the ore must be roasted twice, the second time adding carbonate of ammonia. After roasting, test as with oxidized ores.

THE "grub stake" proposition is always a good one. It can be called a mine hunt, or a mining partnership, or anything else, but the original name expresses the idea. Just how it works is exemplified in the case of C. M. Taylor of Phœnix, Arizona, who started prospecting this week in northern Mexico. His arrangement is with the Mexican Mining & Development Co. He has the States of Sonora and Sinaloa, Mexico. He gets $3000 for expense money, $1000 down, the remainder in installments of $200 per month. He has the right to form a company of his own, and confine his work to prospecting or investigation of and options on mining properties. He reports to the head company, who send an expert to report on the property or prospect. Upon the expert's recommendation the company undertakes to promote the property. On every share of stock so sold Mr. Taylor and his company receive a percentage.

THE manufacturers of the United States imported nearly $500,000,000 worth of materials for use in manufacturing in the fiscal year just ended. Materials for use in manufacturing thus formed nearly one-half of the total imports of the United States last year. The Department of Commerce and Labor, through its Bureau of Statistics, in a table just completed, shows that the total value of manufacturers' materials imported in the fiscal year 1903 was $489,471,667, and that this formed 47.73% of the total imports. In the preceding year the total value of the manufacturers' materials imported was $415,000,000, and formed 46.14% of the total. In 1898 the total importation of manufacturers' materials was $247,000,000 and formed 42.07% of the total.

Mines of Randsburg, Cal.*

From an Occasional Correspondent.

When the present labor troubles in Randsburg, Cal., are settled the camp will enter upon a new period of prosperity. Many independent mine operators are at work. Several of these are men who are on strike; and the properties on whicb they are at work are showing up so well tbat some of the operators may not return to their former work.

Ten miles north of Randsburg, in the Goler mountains, H. J. Short has a low-grade smelting ore property. Still farther to the nortb and east are several low-grade properties which could be handled with profit were there a cheaper method of sbipment.

In the canyons at Goler gold is being extracted from the washes by the aid of tbe dry washer. This is not a satisfactory method in this section, as much cemented gravel is found. Several are working on a machine to disintegrate this hard mass of sand by the aid of water.

The Yellow Aster showed up better and better tbe deeper the shafts and winzes were suuk. The latest ledge struck, at a deptb of 1260 feet, is the richest ever found in this camp. Unfortunately this and several of the other properties here are now tied up by a strike.

The Butte Lode, which controls the Butte and Kinyon-Wedge mines, at the time of the strike was taking out better ore than had been struck for years. Wben the strike was declared this company

Drift, 480-Foot Level, Little Butte Mine, Randsburg, Cal.

was preparing to do extensive development work, to sink to greater depth than at present. This work will be pushed when tbings start up again.

I note in several mining journals that tbe Johannesburg Gold Mines Co. expect to declare a dividend in October, and stock is offered for sale. As far as can be learned the output of bullion from this property did not pay expenses, and as it bas been tied up by the strike for over two months it would seem that the only way the directors can declare a dividend would be from the money received from tbe sale of stock.

The War Eagle Co. announced some montbs ago that it was going to sink a double-compartment shaft to a deptb of 600 feet. Altbough this property

*See illustrations front page.

adjoins the Yellow Aster, and claims that several of the latter company's ledges run tbrough their property, very little work has been done.

Several men are now working the placer deposits

Drift and Stope, 321-Foot Level, Little Butte Mine, Randsburg, Cal.

in Red Rock canyon and making good money.

The stamp mill in Mesquite canyon is still idle. It is called "The Monument to Folly." The company first built the mill and then went prospecting for ore. Tbey met with the usual fate.

The Pearl Wedge, owned by Balschweid & Pierce, although not very large is quite rich. Ore taken from it runs $100 to the ton. There are a number of men now at work on it.

Tbe Santa Ana, owned partly by the owners of the Red Dog mill and partly by Superintendent Layton, is also a rich proposition, averaging $100 per ton.

Jobnson & Jensen are placer mining in the Stringer district, 2 miles from Randsburg. Tbey struck bedrock at 40 feet.

The Baltic mine, in Stringer, is developing into one of the good properties of the camp. At tbe time of the strike twelve men were employed in the mine and mill (ten stamps). Some good ore was being taken out. C. H. Wynn was superintendent.

An attempt will be made to work the tailings of the Garlock mill. A plant is being installed for that purpose.

A. Castro et Cie are placering in Iron gulcb. They sank one shaft 110 feet in an endeavor to strike bedrock. They then moved up farther in the channel and are down about 60 feet.

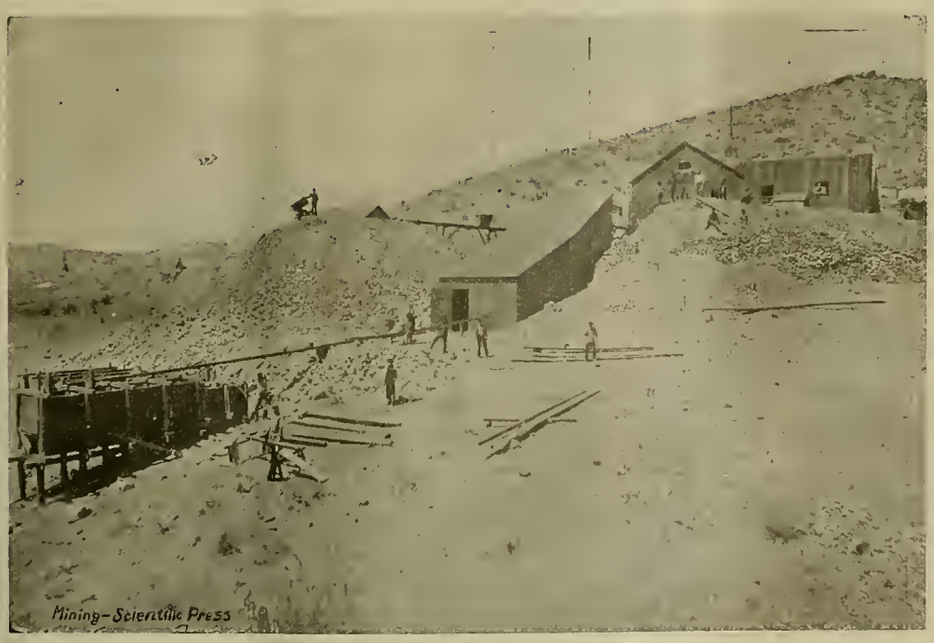
Wiggins & Short are taking $90 ore out of the La Crosse claim.

White's Camp is flourishing under the superintendence of Superintendent Boucbard. Mucb development work is being done.

The Sunshine mine was first located in 1896, but nothing was done in the way of development work for eighteen months. The mine is owned by T. W. & B. M. Atkinson, who are pushing operations. The vein varies from 2 inches to over 2 feet thick and the ore is rich. The Atkinson Bros. also own the Hatchet and Bully Boy claims, on which they have given a number of leases.

A rich stringer has been struck in the Wells-Fargo, situated southeast of town. W. Logan is working it for the owner, Mr. Warner.

White's Camp, or more properly the Sydney group, is active. Tbe main shaft is down 100 feet; two drifts are being run from the lowest level. Another shaft is being sunk 175 feet from the main sbaft to connect witb the stope on the 70-foot level to get a good supply of air.



L. & G. Kane have invented a new placering machine. Water is to be used in it to disintegrate the cemented gravel, and unlike the other one mentioned in this correspodence a plate is used.

It is a pity that more active development work cannot be done in Colorado canyon, northwest of Randsburg. Tbere is a large vein of good coal there.

E Hammond and S. Oakley are down 140 feet on the Orphan Girl and are now drifting on tbe 130-foot level.

G. A. Fudickar, of the Mattie mine, has suspended operations until cool weather.

(More recent reports from Randsburg are to the effect that the negotiations for the settlement of the miners' strike bave not resulted satisfactorily. The Desert Mine Owners' Association, in conference with the Miners' Union, refused to pay more than the old scale, $3.50 for sinking shafts, and $3 for stoping and drifting; the union insists upon a straight $3.50 a day for all miners, regardless of the class of work, and $3 for shovelers. It is stated that 200 non-union men are to be sent to the Yellow Aster.)

Little Butte Mine, Randsburg, Cal

Value of Mexican Exports.

The following statement sbows amount in Mexican silver dollars of Mexico's export trade eacb fiscal year from 1881-82 to 1901-02, average value of the Mexican silver dollar in New York during each year of that period, and these annual amounts reduced from silver to gold at the corresponding yearly average value of tbe Mexican silver dollar in New York:

	Export. Silver Value.	Average Value Mexican Dollars in New York.	Export. Gold Value.
1881-82	$29,206,772	0.894	$26,110,854
1882-83	41,919,182	0.882	86,972,719
1883-84	46 861,117	0.875	41,004 477
1884-85	56.811.958	0.864	40.445.532
1885-86	43 797.249	0.816	35,738.555
1886-87	49,329.015	0.790	38,970,633
1887-88	40,078,717	0.759	87.232,746
1888-89	60.380.287	0.739	44,621,032
1889-90	62,680,539	0.758	47,511,849
1890-91	63,425,746	0.837	53.087,349
1891-92	75 660,880	0.837	63 328,157
1892-93	88,044 624	0.657	57.845 318
1893-94	80,083 944	0 539	43 165,246
1894-95	95,020 326	0 514	48 840,448
1895-96	110,022 356	0.536	58 971,983
1896-97	117,784 092	0.506	59,127 614
1897-98	138 068 504	0.448	61,854,690
1898-99	148 453 834	0 471	70,070,210
1899-1900	158 247,933	0.476	75,326 016
1900-01	158 009,437	0.488	77,266,639
1901-02	168,041,272	0.441	74,106,201

The silver value of Mexico's exports in twenty-one years increased; the gold value did not increase in corresponding proportion. The increase in Mexico's exports in silver value in 1901-02 is $138,834,500 over exports in 1881-82; apparent increase in gold value, $47,995,345, applying average value of the Mexican dollar in each respective year. If the average value of the Mexican dollar in 1881-82, namely, 0.894, be applied to the silver value of the exports in 1901-02, the result is a gold value of $150,000,000 in round numbers, as compared witb $74,000,000 in gold value which results from the average value of the Mexican dollar in 1901-02, namely, 0 441, showing a loss for Mexico in her own silver dollars of $76,000,000.

Production of Chromite in 1902.

The report to the United States Geological Survey on chromite for 1902 by J. H. Pratt is now in press.

California was the only State producing any chromite during 1902, the quantity being 315 long tons, valued at $4725. This is a decrease of 53 tons in quantity and of $1065 in value as compared with tbe production in 1901, whicb was 368 long tons, valued at $5790.

The Pacific coast offers a promising field for the erection of a chemical plant to treat chrome ores in the manufacture of various chromium salts, as these ores can be obtained in California.

With the completion of the railroad from Erwin, Tenn., to Marion, N. C., the chromite deposits of Yancey county, N. C., will undoubtedly be thoroughly exploited and may become producers.

There is a large amount of chromite ore imported each year into this country, the most of which is from Turkey, with smaller amounts from New Caledonia and Canada. The imports of chrome ore and chromic acid in 1902 were valued at $593,712. The principal chromite deposits of Canada are in the vicinity of Black Lake and Colraine, Quebec province. The Canada production for 1902 was 900 long tons, valued at $13,000.

Notes on the Metallurgy of Copper of Montana.*

NUMBER V.

Written by H. O. HOFMAN.

The hearth in some plants is supported by jack-screws, in others it is built up solid from the foundations. It rises some distance above the furnace floor in order to furnish the height necessary for the forehearth or settler and the disposal of the waste slag. The hearth is lined to a depth of 24 to 30 inches with firebrick, or only with one or two courses of firebrick, and then with a mixture of quartz and clay. The crucibles have a depth varying from 8 to 28 inches. Although deep crucibles last rarely longer than three months and shallow crucibles have a longer life, the former are more common. Preliminary experiments with lining deep crucibles with chrome brick have given promising results in preventing break-outs of matte. There appears to be no a priori reason for having a continuously discharging crucible as deep as 28 inches; 8 to 10 inches would seem to be sufficient to furnish the matte bath necessary to cover the bottom satisfactorily, but this is disputed by the best of authority. In treating zinckose ores the deep crucible would probably soon fill up with mushy matte and cause indefinite trouble, but the ores smelted, fortunately, contain very little zinc.

It is claimed that with a deep crucible a furnace puts through more charges, but this has, so far, not been proved. As far as the strength of the jackets is concerned, the deep crucible is preferable, as with a shallow crucible the tuyeres are located higher up (viz., 24 and 12 inches—see table), in order to furnish a smelting zone of some height, and the water-cooled breast has to be built in the jacket, while with the deep crucible it is placed underneath the jacket.

The slag-matte mixture is usually discharged from the center of one of the sides of a furnace. The water-cooled tymp is made of cast iron or, preferably, of copper. Experiments with copper and copper alloys gave the following data:

Life, Days.	Cu. Per Ct.	Zn. Per Ct.	Al. Per Ct.	P. Per Ct.	Sn. Per Ct.
365	100	....	....	Some.	....
144	90	....	0.5	....	10
75	89	3.0	0.25	....	8

The solid cast iron spout with water-cooled nose is very common. Wrought iron pipe surrounded by cast iron has proved unsatisfactory. A water-cooled wrought iron spout with a cast copper removable nose lasts about 120 days, and is often preferred to cast iron.

The tuyere stock in common use consists of a cast iron tuyere box firmly attached to the jacket and connected by a sheet iron tuyere pipe, having a gate, with the bustle pipe.

The large size of the roofless forehearth in which the matte settles out from the overflowing slag is a development of Montana practice, caused by the necessity of storing considerable quantity of liquid matte for the converters. As far as the settling of matte is concerned, oval and oblong hearths are sufficient, as the freedom of copper in waste-slag depends to a large extent upon the length of the path the slag can travel before it overflows. In regard to storage capacity and strength of vessel, the circular hearth is preferable, hence it is only with a comparatively small blast furnace not furnishing direct matte that we find the oval or oblong forehearth. The circular forehearth, 14 feet in diameter and 56 inches high, with a 9-inch brick lining and a 9-inch brasque backing, holds about 60 tons of matte when new. In order to prevent breaking out, the shell is sprayed with water. After being about three months in use its capacity has decreased by building that it becomes necessary to renew it. The 9-inch course of brick sometimes has a 3-inch backing of sand, which seems to be sufficient. The smaller oblong hearth has, as a rule, cast iron water jackets on the sides; it has a 9-inch bottom, which crusts up about 6 inches. The sides are lined with a half course of brick, a 1-inch air space being left at the water jacket. All forehearths have, of course, a tapping slot for matte. It is closed in a few instances by a cast iron plate, but more commonly by a solid copper plate with tap hole. The matte is tapped from the forehearth into a ladle, which discharges its contents either into flat cast iron moulds, holding about 3000 pounds, or into the converter. The practice of bringing the converter to the forehearth of the blast furnace has become obsolete. The blast furnace forehearth, if of large size, is of great assistance to the reverberatory matting furnaces in a plant which converts matte, as it makes little difference whether the forehearth contains much or little matte. It can be allowed to fill near the top, or it can be tapped nearly dry. With the reverberatory furnace this is not the case. The aim there is to allow the level of the matte to fluctuate as little up and down as possible. This means that only a certain quantity of matte can be tapped at stated intervals. If, therefore, the converter calls for matte, and the reverberatory furnace can furnish only an insufficient amount, there is the blast furnace forehearth, forming a kind of balance wheel, to help over the difficulty. The waste-slag is caught in tilting waste-slag pots of 5 to 6 tons capacity and hauled up to the dump, or it is granulated. Near the bottom of the launder carrying the slag granules there is found often a mechanical sampler, driven by the granulating water, which takes out the whole of the stream of granules at stated intervals and furnishes thus a true sample of all waste-slag made.

The coke used around Butte comes from different parts of the country. Most of it, however, is made from Montana coal.

In the management of a blast furnace the tendency has been toward large tonnages, with production of 50% copper matte, and slag low enough in copper to be waste product. Tonnage had to contend with siliceous ores low in iron, and with limestone as the only available flux, which caused the making of slags of high melting temperatures. As, furth r, large amounts of limestone are required to make slags that are at all fusible, the formation temperatures lie higher than when there is a more intimate contact of acid and base. Tonnage was, therefore, obtained mainly by increasing the size of the furnace. The combination of siliceous slags low in iron, with much air, has been the cause of as much as 70% of the sulphur in the charge being burnt off in its descent through the furnace. But even with the large elimination of sulphur in a comparatively dense charge, it is often not possible to obtain the 50% matte demanded by the converter plant, hence blast furnace matte is sometimes tapped from the forehearth into a ladle and poured into the reverberatory matting furnace to raise the percentage of copper by mixing with higher grade matte. The following table gives in percentages some idea of how the charges are made up, and the succeeding table shows partial analyses of flue dust and briquettes, giving an idea of their general character.

*The matte comes in part from the reverberatory matting furnace, which had to be tapped when the converter plant was not ready. In part it is purchased matte to be remelted for the converter.

†The converter slag always goes to the blast furnaces, as it furnishes coarse material, aids the smelting, in having been already once smelted, and acts as a basic flux. Experience has shown that it not only does little good in the reverberatory matting furnace, but that it does harm, in that it increases the amount of slag to be skimmed, and reverberatory furnace slags run higher in copper than blast furnace slags.

‡The briquettes are a mixture of flue dust with 3% to 4% slacked lime. Sometimes slimes from the ore dressing works are added to make up the mixture.

Modern Methods in Ore Treatment by Cyanidation.*

NUMBER II.

Written by EDWIN O. WATT.

Experiments made by Mr. Dunstan on the Associated Gold Mines indicated that it was not necessary to raise the air pipe as high as the bottom of the lift column, and that the escaping air readily passed up the lift column rather than through the outer well. This result was confirmed on the Hainault mine. On the Hainault mine a 4-inch 27-foot lift, working from a 20-foot well, would take only two-thirds of the pulp from a 10-stamp battery. Fig. 4 illustrates the

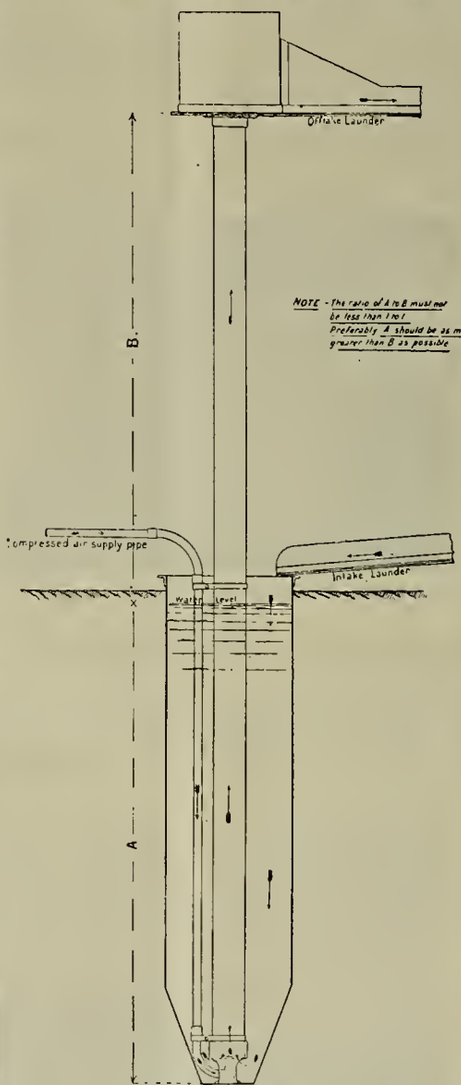

Fig. 4.—Air Lift.

air lift and Figs. 5 and 6 the arrangement of spitzkasten. A 5-inch column gave better results, but a 6-inch column proved much more satisfactory. On the Kalgurli mine an 8-inch lift is raising about 130 tons dry weight of sand and slime per twenty-four hours. This ore has a specific gravity of three. It has been found that on this product the lift will not work at all unless there are four parts of water by weight to one of ore, and it will not work satisfactorily unless the water is in the proportion of five to one; when the proportion of water falls below this point the lift works irregularly and immediately belches air heavily at the top of the column, and soon ceases to work altogether. These proportions have been determined by a series of accurate tests. I think that on more slimy pulp a less proportion of water would suffice. Under all the circumstances with which I am familiar, air lifts have been worked as a portion of an ore treatment plant, and have drawn their supply of compressed air from the general service supply; in no case within my experience have air lifts alone been worked off any compressor, but in every case the compressed air has been split up and used for other services at the same time, and under these circumstances it has not been found possible to

*Trans. Australian Inst. Min. Engrs. (Condensed.)

collect exact data as to working costs. The arrangement of spitzlutten is shown in Fig. 7. At the Kalgurli mine a pressure of thirty pounds per square inch was required for the agitators and filter presses, while the maximum pressure required for air lifts alone was only ten pounds. Thus, although the maximum air pressure required was not as great as usually obtains when rock drills are supplied off the same service, yet even this pressure was unfair to the air lifts, as on all the air supplied to them the power required to compress the air from ten to thirty pounds per square inch was lost. One of the objections to the air lifts is that in order to obtain the best efficiency they should be supplied from a special low service compressor, and under most conditions this is not convenient.

Some of the advantages of air lifts are that they are cheap of installation, and can under many conditions be worked where it is almost impossible to work pumps. On the Kalgurli mine the precipitation from the pulp of sulphate of lime clogs up the pumps, causing serious delay and heavy wear and tear of the parts, and although this accretion forms also in the air lifts, by installing them in duplicate there is no loss of time, and only a slight expense in effecting repairs. Then, again, for air lifts the only connection necessary with the power of the plant is a small pipe, and the loss of power in transmission is very slight. In my experience of air lifts I have never known any of the parts wear out, and I have not seen a lift, when properly served, cease working from any cause that could be charged against the lift itself. Although they do not show a high percentage of efficiency, they might, under certain circumstances, when the continuity of the operation is an essential factor, prove as economical as pumps, when loss of time and wear and tear are fully allowed for.

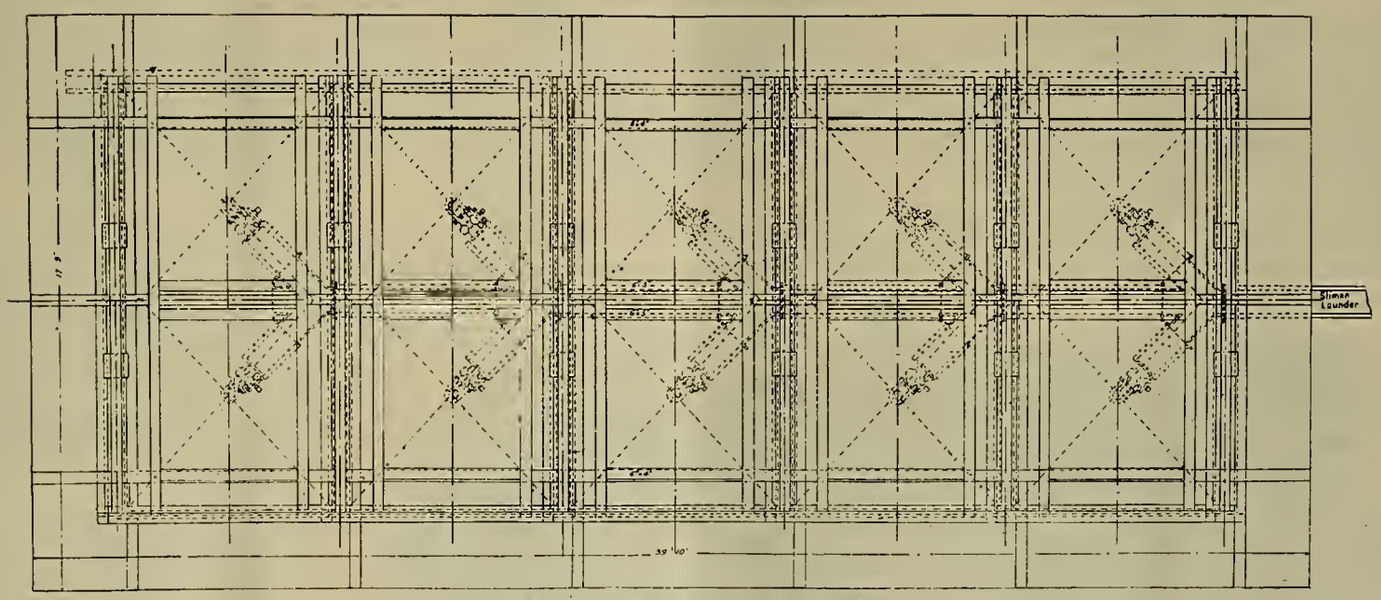

Fig. 6.—Arrangement of Series of Spitzkasten.

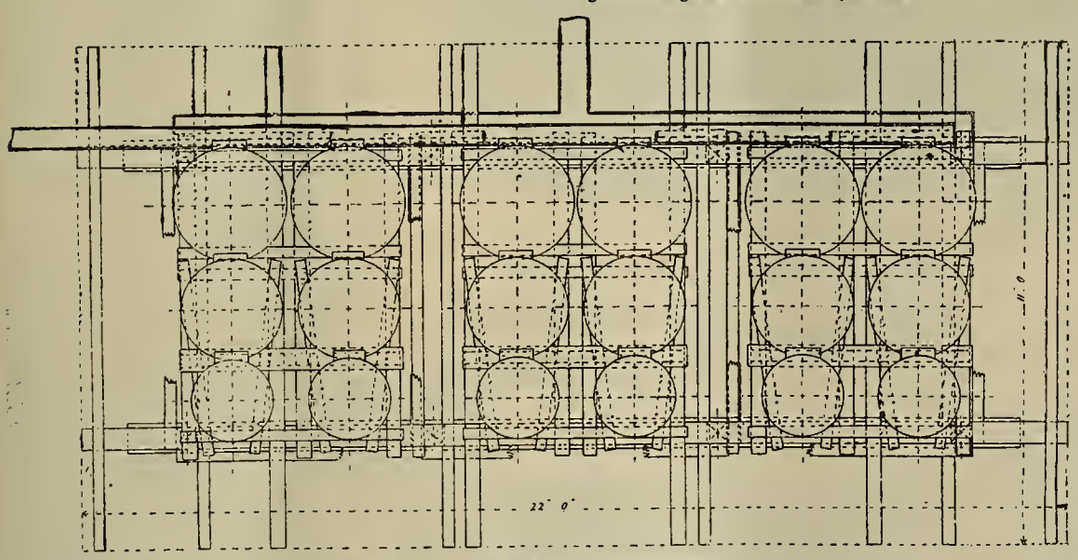

Fig. 7.—Arrangement of Series of Spitzkasten.

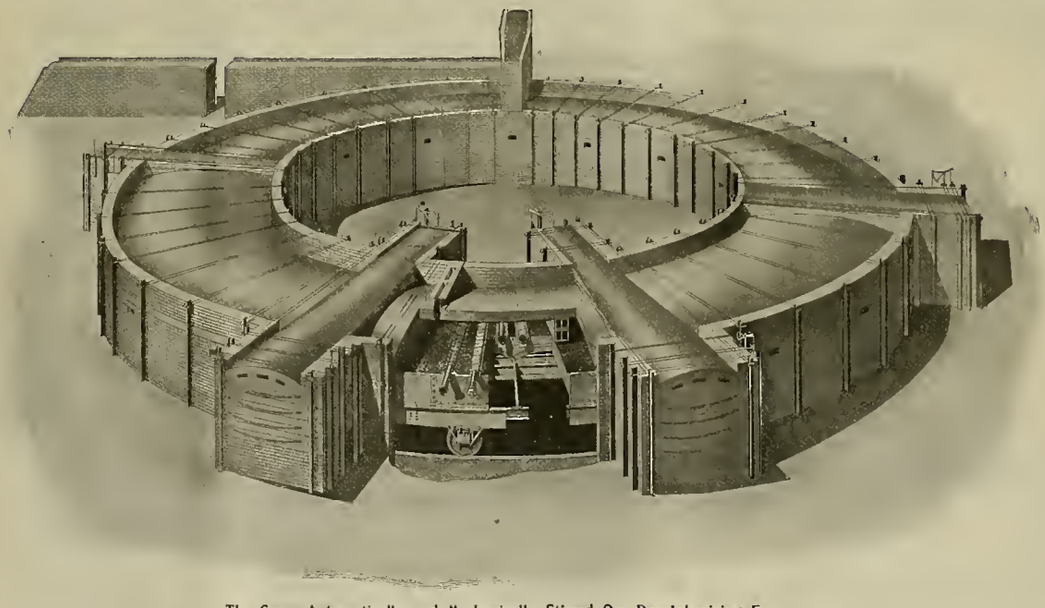


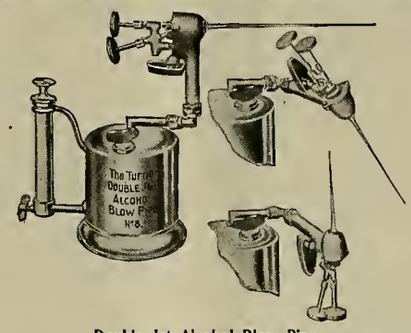
PNEUMATIC AGITATORS.—On the Kalgoorlie field the usual practice for the treatment of auriferous slimes is to stir it with cyanide or bromo-cyanide solutions in steel vats with mechanical agitators for a period of from sixteen to twenty-four hours, afterwards charging it into pressure tanks and thence to filter presses. On the larger mines there are two exceptions to this rule, viz., on the Golden Horseshoe mine, where the slime is pumped direct into filter presses, and cyanide solutions are afterwards pumped through at high pressure, and on the Kalgurli mine, where the slime is agitated by compressed air for three hours. It is with the latter process I wish to deal. The advisability of introducing oxygen in some form to the solutions during cyanidation is generally recognized by all metallurgists and cyaniders, and many experiments have been made of late years with the object of obtaining a cheap and reliable method of accomplishing this end. About twelve months ago experiments were started on the Kalgurli mine with the object of determining whether or not the pressure tanks for the charging of the filter presses could not also be utilized with advantage as pneumatic agitators. It had been previously noted, that when slime was allowed to stand in the pressure tank and compressed air was allowed to flow through the pulp to prevent its settling, a higher percentage of gold was extracted from the slime thus treated, than if it were allowed to pass directly through from the mechanical agitators to the filter presses. Slime pulp, previously untreated by cyanide, was then allowed to run into the pressure tanks, where cyanide solution was added, and the whole pulp gently agitated by a stream of air for five hours. Some idea of the amount of air being used for this purpose may be formed when I say that it was about as much as

would be blown from a good blacksmith's bellows. It was found that after five hours' treatment in this way the extraction of the gold contents was about 5% higher than when the slime was agitated by mechanical stirring for twenty-four hours, and that the cyanide solution came away 35% richer in available cyanide than was the case after stirring. The time of agitation was then reduced to three hours, and an equally good gold extraction was obtained with a somewhat smaller consumption of cyanide. After two hours' agitation the gold extraction was not so good, but further experiments showed that an equally good result could be obtained in two hours when a larger volume of air was allowed to pass through the slime. A sample of concentrated sand was then treated in the same way. Before treatment 87% of this sample remained on a screen of 110 holes to the lineal inch, and the gold contents were equal to four ounces seventeen pennyweights per ton. After three hours' treatment only 34.7% of the sample remained on the same screen, and the residues assayed under three pennyweights per ton, thus showing that in three hours 32.3% of the sand had been reduced to slime, and a gold extraction equal to nearly 97% had been obtained. The exhaust air from the treatment of this sample came away warm in consequence of the friction generated by the sand particles grinding against each other. Subsequent grading analysis showed that this grinding action was always very marked when the pulp contained a large proportion of sand, but that, when fine separated slime was under treatment, there was only a slight diminution in the size of the particles, and under these circumstances the air came away cool. All these experiments were made on roasted sulpho-telluride ore.

(TO BE CONTINUED.)

The Gross Automatic and Mechanically Stirred Ore Desulphurizing Furnace.

Illustrated herewith is the Gross automatic and mechanically stirred ore desulphurizing furnace, manufactured and furnished by the Colorado Iron Works Co., of Denver, Colo. In their latest trade treatise on smelting practice and equipments they instance one of the main difficulties encountered in mechanically stirred roasters in custom smelters, as being the lack of flexibility of manipulations to accommodate various grades of ores or mixtures, and state that the object of designing the Gross automatic and mechanically stirred desulphurizing furnace has been for the purpose of desulphurizing a great variety of ores now being roasted in the hand reverberatory furnace. In an automatic and mechanically stirred roaster, this demands flexibility of manipulations as in the hand roaster.



The Gross Automatically and Mechanically Stirred Ore Desulphurizing Furnace.

It will be noted that the circular hearth is carried upon I-beams and car wheels, revolving on a circular track. The stirring and discharging device remains stationary, the stirring, rabbling and discharging being carried on in a compartment in which it is designed that the ore may be stirred as violently as desired and practically no loss of dust. In this furnace the manufacturers state that ore may be retained on the hearth as long as necessary, the furnace not being a continuous discharge, and that this makes it a desirable machine where different ores require more or less time to accomplish certain work. All stirring and rabbling being carried on in the compartment above alluded to, the ore as it passes through the fire and draught remains quiet, with minimum amount of loss in dust. The stirring and discharging device being in combination, the one set of rabbles discharges the roasted ore from the hearth whenever desired. By a simple attachment, the stirring device can be immediately adjusted so as to leave a given surface of ore exposed to the heat any length of time desired. In stirring continuously, ore surfaces are stirred every two minutes, more or less, the speed of hearth and motors driving same being regulated by a speed-controlling rheostat.

Double Jet Alcohol Blow Pipe.

The Turner Brass Works, 53 North Franklin street, Chicago, are manufacturers of the Turner double jet alcohol blow pipe illustrated herewith. This article is just being placed upon the market. The high

Double Jet Alcohol Blow Pipe.

temperature generated by this blow pipe, together with the needle point non-oxidizing flame, makes it valuable to any one who requires a hot clean needle flame for fine soldering. It is designed to replace the oxy-hydrogen blow pipe for lead burning in the connecting of lead storage batteries, and proves the cleanness and non-oxidizing quality of the flame.

The blow pipe is started by pumping a strong pressure into the reservoir by means of the pump contained in the handle, then opening the lower valve and allowing the alcohol to flow into the cup below the burner. The valve is then closed and the alcohol in the cup lighted with a match. Its burning heats the burner sufficiently to generate gas, which is ignited by opening the lower valve again and holding a lighted match in front of the burner. The flame is then regulated by opening the upper valve to the desired extent.

This blow pipe generates a temperature of over 3000° F., and has the capacity to melt pure gold. It will also flow 25% platinum solder.

Full descriptive circulars, prices, etc., will be furnished by the manufacturers of these blow pipes on application.

Cedros Island Ores.

From Mr. George S. Binckley, consulting engineer, Mills building, San Francisco, Cal., is received an unusually fine specimen of native sulphur, taken from the Sulphur Point mine, Cedros island, Lower California, at a depth of about 10 meters below the surface. The surrounding ore is highly oxidized, no fissure structure of vein apparent, but the streak of sulphur is comparatively continuous, on a dip of about 45°. Different assays of this material have given results varying from $16 to $60 per ton of gold. Sulphur contents are not determined, but the ore burns readily with a match. The gold in this ore does not amalgamate at all readily, and is, although free, probably coated with sulphur, as in many of the ores from the adjoining mines this is the case.

Among the ores found in these mines, all within a radius of 500 meters, are the following: Oxidized gold ores, being in many cases siliceous skeletons, very light and friable, retaining some fine iron sulphides, and carrying a small amount of copper in the shape of finely disseminated sulphate. These ores also carry sometimes from 10% to 17% of free sulphur: Oxidized ores consisting of mineralized volcanic breccia, carrying a very variable value in gold and silver, and generally a very small amount of copper: Sulphide ores of same class as above, carrying values from a few cents to $250 per ton in gold: Higher values of this class are generally more siliceous, but not always, as some of these ores which appear to be black shale (due to movement in the plane of the deposit), carry over $100 per ton: Native copper, with a siliceous skeleton, carrying from $16 to $60 per ton gold: Bornite, with gold and silver, gold often free and visible to the eye, but in this case is found in siliceous veinlets in the body of the bornite—appears to have been secondary deposition, as well as the bornite itself: Bornite associated with galena, gold and silver, in this case generally free.

A complex ore of lead is also found as galena, with iron and zinc sulphides, carrying high values in gold and silver. This ore is taken from the same stope and streak as some of the purest bornite—in fact, the bornite is found within a streak of lead carbonate, more or less mixed with waste, in which occurs the lead sulphide ore described above. Value of this ore is from $45 to $78 per ton in gold and silver. There is likewise found chalcopyrite, with little value in gold or silver; a copper ore very high in iron, but very low in silica, about 12% cu., besides a very peculiar sulphide ore, carrying often high values in gold, some copper, and iron in an unusual form, very refractory, and often high in zinc sulphides, not siliceous, and slimes badly, although hard to drill and crush.

Besides these there are a mineralized breccia, often high in gold, but very heavy in zinc; an ore having a matrix of more or less pure barium sulphate, carrying excellent values in gold and silver, but in which the vein falls in continuity at a depth of about 12 meters; copper silicate, natural sulphate, black oxide, carbonate high in gold ($100), and native copper in the interstices of diabase country rock.

Points on Placer Locations.

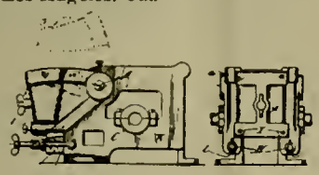
Written for the MINING AND SCIENTIFIC PRESS.

Under the United States placer mining laws one person may make a single location containing 20 acres of placer mining land; two persons may make a single location containing not more than 40 acres in a compact body; three may locate 60 acres, etc., but no single location, whether made by eight persons or more, can exceed 160 acres.

It has been decided that a single location of placer mining ground may embrace 20, 40, 60, 80, 100, 120, 140 or 160 acres in a compact body, according to the number of locations.

If eight persons should make eight distinct and separate locations of 20 acres each, and seven of the locators should convey their claims to the other, it would require annual assessment work of the value of $800 to maintain the possessory right to all the claims; but, in the case of a single location, embracing 160 acres of placer mining land, the owner thereof, in order to maintain his possessory right thereto, would not be required to expend $100 worth of mining labor on each 20 acres thereof, but his possessory right to the entire 160 acres might be maintained by performing thereon $100 worth of actual mining work designed in good faith for the improvement of the 160-acre location as a single mining claim.

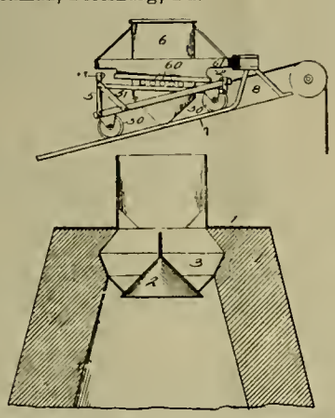
The law permits a single person to take as many placer claims of 20 acres (no more) each as he may desire, and they may be contiguous or not, but requires a separate discovery for each separate 20-acre tract. Where more than one person (not exceeding eight) participates, an area equivalent to 20 acres for each is permitted, but they locate the area jointly and are not required to locate each particular 20-acre tract, becoming tenants in common of the entire area. Placer ground so taken also requires separate discovery for each 20-acre tract of 160 acres. A single member of the party may act as agent for each of the others and locate each of the several tracts.



If several persons locate contiguous claims in common, such act would in itself constitute copartnership, and the proceeds of such operation should be equally divided, unless stipulations to the contrary were entered into by all the members of the party holding such claims jointly. Where the land has been legally subdivided, tracts of 40 acres may be subdivided into 10-acre tracts; but where no legal subdivision of the public lands has been made, claims may be located with reference to the stream or bank along which the placer occurs. Any one member of such association may, if legally constituted an attorney-in-fact, transfer the property to another individual or company.

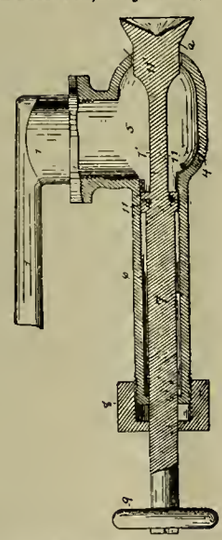
Mining and Metallurgical Patents.

PATENTS ISSUED AUGUST 18, 1903.



Specially Reported and Illustrated for the MINING AND SCIENTIFIC PRESS.

ASSAYER'S ORE-CRUSHER.—No. 735,942; A. C. Calkins, Los Angeles, Cal.

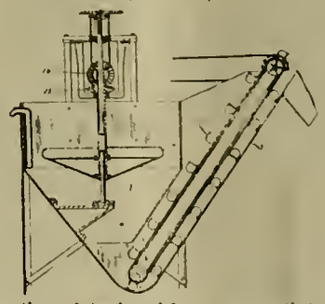


An ore crusher comprising main casing, movable jaw, relatively stationary jaw having side pieces to form crushing chamber, side pieces being hinged respectively at upper ends to main casing so as to be turned outwardly and up over other jaw.

CHARGING CAR FOR BLAST FURNACES.—No. 736,352; G. W. Bollman, Pittsburg, Pa.

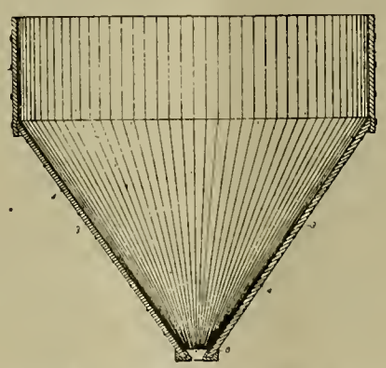
In dumping car, combination of car frame, part adapted to contain load, being free to move back and forth on car frame, means for keeping part which contains load normally at one end of car frame, means for stopping part which contains load at fixed point near end of travel of car frame.

OIL BURNER NOZZLE.—No. 736,487; H. E. Brunner and E. J. Patterson, Haywards, Cal.



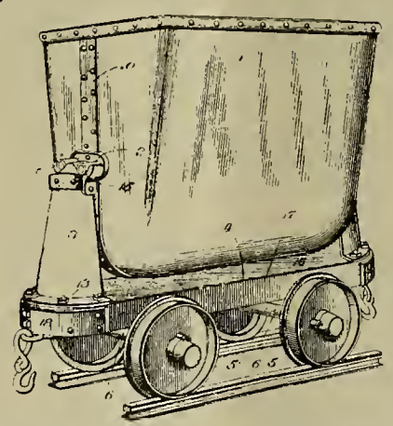
Oil nozzle comprising shell casing having enlarged chamber for oil, provided with outlet opening, operating stem passing through oil chamber, elongated plug carried by stem working loosely through outlet opening of casing to provide unobstructed passage around plug between same and inner surface of casing, plug of uniform diameter throughout, enlarged relative to diameter of stem, a spreader carried by outer end of plug arranged to constitute valve for outlet opening.

PROCESS OF MAKING NICKEL IRON ALLOYS DIRECTLY FROM ORES.—No. 736,400; N. V. Hyhinette, Bayonne, N. J.



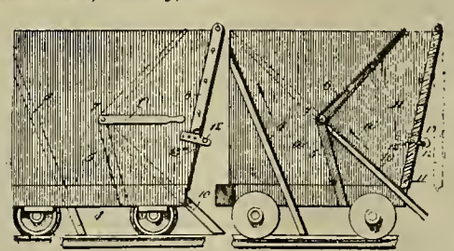
Of producing nickel-steel from ores composed mainly of sulphides of iron, nickel and copper, consisting in roasting ore with salt, heating material so as to decompose chlorides of iron and nickel, leaching out chloride of copper, then reducing residue directly into nickel-steel.

GOLD WASHING MACHINE.—No. 736,464; T. F. Turner and H. B. Stewart, Canton, Ohio.



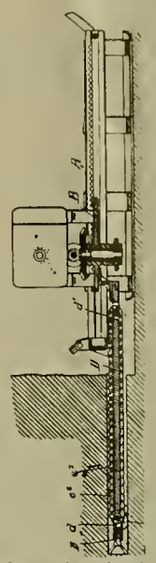
Combination of tank with upper outlet passage, extended into tank to point below surface of water in tank, provided with concave bottom, elevating buckets located upon elevating chains, extended into bottom of tank, movable concentrically over concave bottom, an inclined way extended from concave bottom and submerged centrifugal pan located in tank, means for rotating centrifugal pan.

TANK.—No. 736,520; A. Holtgen, San Francisco, Cal.



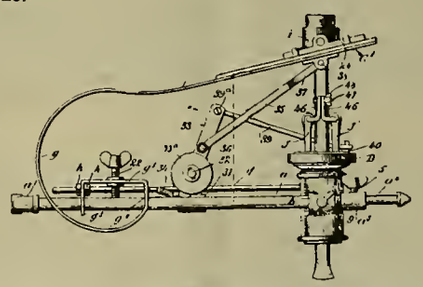
Tank of character described formed of plurality of staves and hoops for securing same in place, provided with knock-down substantially funnel-shaped bottom formed of radial staves, and series of removable hoops exterior to bottom staves fitting grooves therein for temporarily securing staves in place, in combination with auxiliary means for closing opening at lower edges of bottom staves.

MINE CAR.—No. 736,561; T. Stagg, Columbus, Ohio.



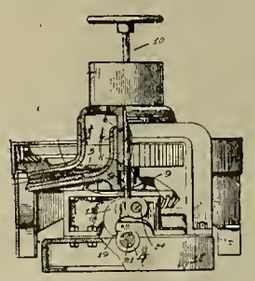
Combination of body having trunnions, standards having trunnion bearings, longitudinal base from which standards project upwardly, base forged from wrought metal into flat top having rounded ends and continuous vertical flange integral with and conforming to outline of top, rounded ends provided with reinforcing buffer plates.

ORE DUMPING APPARATUS.—No. 736,882; N. A. H. Salomonson, Norway, Mich.



Ore dumping car comprising body having fixed rear side, front partition arranged transversely extending to point near center of car, movable partition journaled at that point adapted to be shifted front or rear, front door hinged at upper end adapted, when closed, to engage partition, when released, to hang free to allow discharge of material received upon partition, means for locking door.

MINING MACHINE.—No. 736,705; H. B. Dierdorff, Columbus, Ohio.



Combination with carriage having portion arranged to enter kerf cut by machine, series of cutters carried by carriage, holding device for carriage consisting of endless chain adapted to engage with wall of kerf, provided with flanges e^4, chain being arranged with one portion or limb above carriage and another portion or limb below carriage, supporting means for lower limb or portion of holding chain arranged to engage with flanges e^4 and support chain.

ROCK DRILL.—No. 736,758; C. Mead, Murray, Idaho.

In rock drill, combination with casing and tool guided therein, of bars slidably fitted in casing, springs connected with bars to draw them toward casing, clamp attached to bars having means for tightening same, corrugated gripping rollers supported by clamp engaging with tool, dogs to restrain rollers from rotating in one direction.

QUARTZ MILL.—No. 736,519; C. J. Hodge, Houghton, Mich.

In quartz mill combination of two relatively movable grinding cones, one provided with vertical sleeve, the other with pivot arranged in sleeve, nut located in sleeve supporting pivot, screw passing through pivot and nut, pivoted lever supporting screw, driving shaft, and cam engaging lever.

A LAROE steam turbine is to be installed in the Rheno Westphalian generating station at Essen, Germany, to run a 5000-kilowatt alternator and a 1500-kilowatt direct current generator at the same time. The turbine must supply 7500 kilowatts of output to run the two machines. The makers say that the new turbine will operate with but 15.5 pounds of steam per net kilowatt hour. The whole set—turbine, alternator and generator—measures 58 feet long, 10 feet wide and the same height; this includes the length of the turbine which measures only 23 feet long for a capacity of 7500 kilowatts.

Mining Summary.

Specially compiled and reported for the MINING AND SCIENTIFIC PRESS.

ARKANSAS.

MARION COUNTY.

Near Yellville, E. Stettnich of Lawton, Ok. Ty., has bought a half interest in the Ike Emory mine for $5500 and arrangements are being made to resume work preparatory to shipping ore.

ALASKA.

An oil strike is reported made between Fort Hamilton and Andreafsky, on the Yukon river.

At Windham Bay the Yellow Jacket mine has its mill ready for operation, says the Juneau Dispatch. The Windham Chief Con. and the California-Alaska have built a corduroy road to the third basin and from there a mule pack trail up under the glacier. Both companies are driving tunnels. The Jennie Reid C. M. Co. has put up buildings and is driving a tunnel on pay ore, showing free gold. The Helvetia G. M. & M. Co. started operations on June 9th and have so far put up several buildings, built a road from the corduroy to its millsite, the millsite and a trail for the water flumes and pipe cleared, foundation for the crusher blasted, and 35 feet of tunnel driven on pay streak.

The Alaska-Treadwell G. M. Co., at Treadwell, on Douglas island, reports for the month ending August 1: The 240-stamp mill ran 28⅞ days and the 300 stamp mill 28⅞ days, crushing 79,384 tons of ore; value of bullion, $80,025. There were 1690 tons of sulphurets obtained, estimated realizable value of the same being $92,182. Working expenses for the month were $79,110.

Because of continued disasters resulting in loss of life, 100 men are reported to have quit work in the Treadwell mine on Douglas island. The men do not make any charge of mismanagement or an unsafe condition of the mine.

Last week at Juneau the Treadwell G. M. Co. and a company headed by D. O. Mills of San Francisco, Cal., bought a group of twenty gold-bearing quartz claims on Berner's bay, near Juneau. The price is stated to be $2,000,000. They will start development work and it is expected a stamp mill will be built this winter.

ARIZONA.

COCHISE COUNTY.

The diamond drill has been put in operation at the Junction Dev. Co.'s property near Bisbee.

F. E. Kennedy of Duluth, Minn., manager of the Kansas City group of claims, adjoining the Gold Reef group in Tombstone canyon, 1½ mile from Bisbee, says development work will begin and a two-compartment shaft sunk.

GILA COUNTY.

President C. S. Smith of the Old Dominion C. M. & S. Co., at Globe, says the effects of the flooding of the mine, due to breaking of a dam, which has cost the company over $200,000, have been nearly overcome.

N. S. Berray has bought the Golconda, Red Hot and Barranca mining claims on the San Carlos segregated strip, adjoining the property of the San Carlos C. Co., near Globe.

Superintendent A. C. Sieboth says that at the Arizona-Hancock mine, near Globe, the shaft has been completed 450 feet in depth, the station cut and the east crosscut on that level driven 40 feet. The west crosscut has not been started, as an increased flow of water is expected from that direction, and a pump will first be put in.

GRAHAM COUNTY.

The Sierra de Oro M. Co. is working a number of miners on its claims 5 miles above Clifton on the Frisco river.

MARICOPA COUNTY.

(Special Correspondence). — Burson & Langley, who recently erected a stamp mill at Buckeye, will put it in operation this week.

Manager Welch of Phœnix has gone to the White Tank mountains to get out ore from his claims. He will have the ore hauled 5 miles to the mill at Buckeye.

The Grijalva Coarse G. M. Co., in which a number of Phœnix parties are interested, report development work in rapid progress, with excellent showings.

G. Hamlin is contemplating the erection of a stamp mill at the Relief mine.

Phœnix, August 24.

G. B. Upton, manager of the Oro Grande mine, near Wickenburg, says he will put in a heavier hoist and build a 5-stamp mill to give the ores a thorough working test, after which a 100-stamp mill will be installed.

MOHAVE COUNTY.

(Special Correspondence).—Work will be resumed on the Tennessee mine. In addition to increased development work underground, the mine will be enlarged and new machinery added.——The Argo mine, on Sherum's peak, is outputting shipping ore. The shaft is being sunk below the 200-foot level, going to 300 feet. Two levels in the mine are producing two carloads of ore per month.

The Elkbart M. Co. proposes to resume work on the mine next week. It is said the 600-foot shaft is in bad shape and work will have to be started elsewhere. There is milling ore in the old workings, but it is intended to open up a new body of ore below the present 600-foot mark.

Superintendent L. Hoffman of the Samoa mine, near Cbloride, reports the mine outputting high-grade silver ore from a new point of opening on the 350-foot level. Besides silver, it also carries values in gold and copper. A 20-jack train makes two trips a day with ore from the mine to the depot of the A. & U. Railroad, the output being four carloads a month.

At the Home Pastime mine, Mineral Park, work is suspended for the present. There is a considerable tonnage of ore of below shipping grade on the dump. Cyaniding is proposed.——S. W. Toby reports a gold find in his and W. Alger's Great West mine.

At the gold strike of Dempsey & O'Dea at Prilgrim, work is progressing on the three 100 foot prospecting shafts in the vein.

Men continue going to the scene of the recent gold find near Kingman, and the ground is monumented for several miles in the line of the mineral out from McConnico Junction.——Mining is quiet at Union Pass, although G. Richardson, owner of a group of gold claims, is doing a little work, with a view of transferring his properties to a company.

The 10-stamp mill at the Virginia mine, 25 miles west of Chloride, is in operation with satisfactory results. The capacity of the mill is not up to the output of ore.

Chloride, Aug. 24.

SANTA CRUZ COUNTY.

The Hermosa M. Co. has been incorporated and has taken over the Hermosa mine at Harshaw. E. E. Conklin, W. S Frasier, H. F. Burt, H. W. Penecost, C. C. Kneisley, N. D McGinley, H. E. Allen, C. B. Adams, B. S. McGuire of Oklahoma and J. S Cunningham of Harshaw are incorporators.

YAVAPAI COUNTY.

The Denver Onyx & Marble Co. has bought the beds of the Arizona Onyx Co. at Mayer, which adjoins their property, says Superintendent Eaton. The two groups will be operated in conjunction. The quarrying of stone continues and the first shipment to Eastern points was made this week.

Bars of gold bullion are being shipped regularly from the Henrietta mine of the Braganza M. Co, near Bigbug, says Superintendent Johns. He has twenty stamps dropping and fifty men at work. A 30 H. P. boiler has been added to the pumping plant.

Superintendent Rankin of the Henrietta mine, having secured a bond on the Nevada group, near Prescott, has started work. The shaft on the Nevada is being retimbered and sunk deeper.

The Monte Cristo mine, near Prescott, has been unwatered and men are being put to work in the mine. The mill is expected to be in operation next month.

The Model G. M. Co. at McCabe is putting in additional machinery. The two 80 H. P. boilers are in place, the gallows-frame completed and the shaft retimbered down 65 feet (as far as it was damaged by the fire which destroyed the mill last spring) The mill is being built 200 feet from the hoisting plant. The ore will be trammed from ore bins at the hoist into the mill. The machinery in the mill will be run by a 35 H. P. gasoline engine, while a 65 H. P. steam hoist will be used at the shaft. The mine is filled with water up to the 500-foot level, but the pumps will be started this week.

It is reported deposits of gypsum have been found east of Mayer.

Seven and one-half miles south of Prescott, at the Home Run mine, Douglas, Lacey & Co. are preparing to build a milling plant. It will be of 6-stamp capacity.

The Mount Union group of mines at Mount Union, near Prescott, have been sold to the Arizona-Michigan M. Co. The company intends to put in machinery and start sinking.

CALIFORNIA.

BUTTE COUNTY.

(Special Correspondence).—The Feather Valley Gold Dredging Co, in the Feather River Valley district, have shipped a driller to their property to test the land in ½-acre tracts. Eight tests so far made run from 13 cents to $1 25 per cubic yard. This property is being tested to determine the exact values in the gravel bed before putting on a dredger.

Oroville, Aug. 24.

CALAVERAS COUNTY.

At the Melones mine, at Melones, sixty stamps are dropping in the mill. Some specimen rock is reported taken out of the Reserve cut last week.

Eighty stamps have been added to the mill at the Gwin mine, making a total of 100 stamps dropping regularly.

All the men were laid off at the Utica mine of the Utica G. M. Co., at Angels, on the 21st inst., and the mine abandoned, as being worked out. The car tracks, air pipes, drills and all machinery under ground have been taken out. The mill will be kept at work until the ore bins are emptied. The old Madison shaft is to be reopened, and some of the men taken out of the Utica will be employed there. The work at the Cross shaft and Stickle mill will not be interrupted. Pumps were taken to the Madison shaft and set up last week.

At the Silver Cup gravel claim, owned by Cuneo & Queirolo, at Fricot, near Sheep Ranch, a shaft has been sunk to depth of 45 feet and pay gravel struck. It is intended to put in a whim and sink an additional 75 feet.——Work is progressing at the Grape Brandy mine, owned by the Smith G. M. Co. of San Francisco, under Superintendent C. W. Saunders. A gasoline hoist has been set up and a shaft sunk to depth of 135 feet. Assays at this depth show $10 in gold.

The Emerald mine, on Indian creek, near Angels, and owned by J. F. Davis, will be reopened at the old shaft.

DEL NORTE COUNTY.

J. S. Crawford, manager of the Cleopatra group of copper mines near Smith River, says work is progressing and development is being increased.

EL DORADO COUNTY.

Work is progressing at the Noonday copper mine near Logtown. A boiler and a machine will have been put in. The property is bonded by the Pelton Chemical Co. and sixteen men are employed, says the Georgetown Gazette.

At the Crystal mine, on French creek, 2 miles south of Shingle, they are preparing to add five stamps to the 5 stamp mill.

It is reported work will be resumed at the Garfield mine, near Josephine, by Manager Chapman.

FRESNO COUNTY.

The New San Francisco Crude Oil Co well, near Coalinga, which was finished last week, is pumping at the rate of 150 barrels per day, says the Reporter.

INYO COUNTY.

The Pacific Coast Borax Co. has men at work on the roadway which it is building from Ivanpah, San Bernardino Co, to Ash Meadows. The road is being built to tap their borax deposits, near Death valley.

KERN COUNTY.

The Associated Oil Co. has completed ten wells on its Central Point lease, near Bakersfield, during the past month, some of which are proving good producers.

The Superior Oil Co. will drill its third well at Sunset after a suspension of one year, says Superintendent E. W. McCutcheon. The company already has two wells ready for pumping.

Machinery for the Karma mill, near Mojave, is on the ground and building will begin Sept. 1. More men will be put into the mine.

Near Randsburg T. McCarthy has begun development on the Teresa mine.——S. J. Montgomery and D. McEachan are working on the Annex mine.

Superintendent Bouchard reports he has begun stoping on the 100-foot level at White's Camp, near Randsburg, says the Miner.——E. Bergman has taken a lease on the Tam O'Shanter claim in Stringer district.

The Junction Oil Co. has started work on its No. 5 well at Kern river, near Bakersfield ——The East Puente Oil Co. started work last week on its No. 7 well. This company is owned by San Diego men. Its holdings amount to ten acres and its production is said to be 12,000 barrels a month, says the Californian.

The Associated Oil Co. has completed ten wells on its Central Point lease in Kern river field, near Bakersfield, during the last month, some of which are proving good producers. Drilling will continue until thirty-six wells have been finished, in accordance with the terms of the lease.

NEVADA COUNTY.

Operations are again under way at the Lecompton mine in Willow valley, near Nevada City. The 10-stamp mill was started last week. The mill and compressor are driven by two 6-foot impulse water wheels under a head of 310 feet, and the hoist is driven by a separate line under same pressure. The plant will be completed by addition of a dynamo and 150 electric lights in the shaft and buildings. The sand plant, capable of handling all the pulp of the mill, is expected to be ready next week, says W. H. Dunlap, superintendent.

G. C. Hayes, who has a bond on the Randolph Flat mine near Rough and Ready, is preparing to increase development work. A hoist and other machinery are going in.

The Sierra Queen mine, near Nevada City, after a short shut-down, has resumed. A larger pump will be put in later on and drifts run on the south side of the shaft to tap the ledge under Deer creek.

The mill of the New York-Grass Valley Con. Co., near Grass Valley, will start up this week. Forty tons of ore on the dump will be milled before rock from the reopened mine is tried. The company reports having a 5-foot ledge in the bottom of the shaft showing free gold.

A 10-stamp mill is proposed for the Zeibright mine, south of Grass Valley and near the Placer county line. F. Zeitler of Nevada City is manager.

J. A. Jeffery of San Francisco, president of the South Yuba M. & D. Co., and C. W. Porterfield, manager, report work begun on the company's gravel mines east of Omega. They have 1500 acres along and contiguous to the Omega channel and have bought the Blue Tent water rights and canal system. A sawmill plant has been set up and lumber is being cut. This fall and next summer they will build 5 miles of flume from the dam at Bear Valley, on the South Yuba river, to Omega.

At Town Talk, near Nevada City, a 2-stamp mill is crushing the gravel taken out of the mine of J. M. & H. Kitts. They are opening up a channel which exists in the Town Talk ridge and tapped it through a tunnel, says the Union.

SAN DIEGO COUNTY.

W. W. Boswell, superintendent of the Helvetia and High Peak mines, near Julian, reports a strike of free gold ore from the High Peak.

SAN LUIS OBISPO COUNTY.

The Tar Springs ranch, 8 miles east of Arroyo Grande, has been sold to W. W. Clapp of Pennsylvania, who has had a bond on the land for $60,000. He will develop the oil prospects.

SANTA BARBARA COUNTY.

A. Carter, of Los Angeles, has bought the wharf at Carpenteria, together with fourteen acres of land adjoining, for putting in a solar furnace plant for manufacture of salt from sea water. Besides making salt, Carter will also build a plant for manufacture of the solar furnaces.

SHASTA COUNTY.

The Eureka Tellurium mine, at Middle Creek, will be put in operation, says the Redding Free Press. The mine is 2½ miles from Redding and has several thousand feet of tunnels and shafts, showing a number of gold-bearing quartz ledges. The Eureka Tellurium vein carries tellurides. The group consists of 290 acres of patented land between Salt creek and the Shasta road.

The Quartz Hill mine, owned by the Original Quartz Hill G. M. Co, will be reopened and development work increased, says M. Maryanski, a director of the company. If satisfactory arrangements can not be made to handle the ore at the Keswick smelter, his company will put up a milling plant on the ground. The mine is in Old Diggings district, near Redding. A. Spetz of Chicago, Ill, is president.

The Iron Mountain Railroad, operated by the Mountain Copper Co. at Keswick, and extending from the smelter to the mine at Iron Mountain, has decided to use oil instead of wood as fuel on its five locomotives. This change closes the use of wood as fuel by the Mountain Copper Co. Four years ago it was using 20,000 cords a year. This change has been brought about by the substitution of electrical power furnished by the Northern California Power Co. for steam, the use of oil for fuel instead of wood in the hot-air blast and at the power houses, and the abandonment of the open-air system of roasting ores, which alone consumed several thousand cords of wood a year.

SIERRA COUNTY.

Suit has been brought in Los Angeles county by the Corotoman M. Co. against the Chinese lessees of the Golden Star mine to recover the sum of $10,000. The two mines are near Forest City. In the complaint the Corotoman Co. alleges the Golden Star Co. has encroached on its ground by means of tunnels and drifts and removed therefrom gold to the value of $10,000.

J. M. Harper of San Francisco, of the Columbia Channel G. M. Co., has begun operations at their mine at American Hill, near Forest City. He has eight men at work running a tunnel to tap the channel.

SISKIYOU COUNTY.

The Schroeder mine on Deadwood creek, near Fort Jones, has closed down temporarily, throwing thirty men out of work, says the Siskiyou News.

TRINITY COUNTY.

Twenty-five men are at work on the Integral quicksilver mine near Altoona, says Superintendent F. Mahon. The company is doing development work, driving shafts and tunnels, and last week a body of ore was struck.——The Altoona quicksilver mine, which was closed down several years ago, is being worked by a party of Swedes, who are working the dump.

There were fifteen lode locations filed last week for claims in Hayfork section.

TUOLUMNE COUNTY.

Dambacher & Co. have put in a hoist on the Telegraph Hill mine, on the Dambacher ranch, near Columbia.

The work of unwatering the Mt. Hood mine, owned by the Rawhide Extension G. M. Co., near Jamestown, is in progress.

A heavier pump is being put in by Superintendent Sharwood to handle the flow of water struck in cutting the ore shoot in the Soulsby mine, at Soulsbyville.

Superintendent Converse, at the Draper mine, near Soulsbyville, says operations will be resumed.

J. Phillips, managing the Los Angeles gold mines group of three claims south of the Tuolumne river, near Groveland, says the 10 stamp mill will be in operation next week. The number of men at work will be increased as soon as the mill starts.

COLORADO.

(Special Correspondence) — The Globe plant is resuming operations as fast as they can get ready. They now have several of their furnaces running.

There is talk of settling the strike at Cripple Creek, but the way things are shaping themselves the operators will have nothing to settle, as it is reported they are able to secure all the men they want. Some of the mines have resumed operations under guard.

Denver, Aug. 24.

CLEAR CREEK COUNTY.

In Upper Union district, near Empire, the St. Paul & Colorado M & M. Co. has bought the Mark Hanna lode and thirty-two other locations.

The Ella McKinney M. Co. of Idaho Springs has added another claim to its group in Cascade district, on Ute creek, buying the Victor lode. The Ella McKinney will be opened later by the Burns-Moore tunnel.

A large shipment of iron concentrates was made from the Mendota mill, near Silver Plume, last week, which had accumulated since the mill has been in operation, only the lead zinc products being shipped heretofore ——Southward & Cavanaugh have taken a lease on a block of ground on the Vulcan, and are opening up a shoot of ore, says the Silver Standard.

GILPIN COUNTY.

Karrigan & Sikes of Leonardsville, Kan., have bought the J. Ingram one-quarter interest in the International group of seven claims, near Central City, for $3000 cash.

It is reported that the Missouri mine, near Russell Gulch, will resume, with P. McCann as superintendent.

New York men are interested in the Gold Run M. & M. Co., operating near the head of South Boulder creek, near Nugget, and they have a tunnel in 200 feet, of which 50 feet is double track. They intend to put in an air compressor plant and drive the tunnel all winter, so they will be able to open up some of the lodes before next spring. W. Lewis is superintendent.

M. W. Tanner et al. of Idaho Springs have a lease and bond on the Gomer mine, near Russell Gulch, and machinery has been put in during the past week and the mine unwatered. The working shaft is down 100 feet and as soon as retimbered the lessees will sink another 100 feet and explore the former workings.——It is reported that the Lillian mine, in Russell district, has been leased to H. Banner of Idaho Springs, who will start developments next week. The shaft is 200 feet deep and it is expected will go deeper.

A sinking pump is being put in by the Powers M. & M. Co., Russell Gulch. After unwatering, the company expect to sink 200 feet from the 220-foot point. The ore bodies are said to be of enargite. Pennsylvanians are interested.

GUNNISON COUNTY.

The Waunita Con. G. M. & M. Co. has been incorporated to operate a group south of the Independent group in Bowerman district; J. F. Simpson, K. C. Sterling, J. H. O'Neill, S. Bell, J. B. Sanford, J. Kent, J. T. Ball and F. McMillan; S. Bell of Denver is president. The company's property consists of four claims a mile south of the Bowerman-Dunn group, being the Wabash and the B. & O. group. A shaft will be sunk on the line between the Wabash No. 1 and the B. & O. lodes. Besides the lode claims, the company owns 100 acres of placer ground which has a sufficient water supply.

The Ethel G. M. Co., owning the Jim John and other mining properties at the head of Yule creek, near Crested Butte, has men sinking a shaft on the Jim John, in which they have struck a 4½-foot vein carrying galena. A contract to run a tunnel which will cut the vein at depth has been let.

Turner & Cantrell of Denver will work the Hard Cash tunnel, near Crested Butte, making shipments to the Gothic mill.

The Augusta tunnel, near Crested Butte, after nineteen months of continuous driving has reached what is thought to be the main Augusta vein, says the Elk Mountain Pilot. The length is 2900 feet. The building of the proposed tram and mill is expected to be started next month. In the meantime drifting on the vein and opening up ore shoots will go ahead.

JEFFERSON COUNTY.

After a shutdown of two weeks the smelter at Golden was blown in again on the 20th inst. A new settler has been put in. Besides the cars of ore now on hand, the Golden smelter slack dump has been bought and will be worked.

LAKE COUNTY.

The repairs at the Resurrection mill, near Leadville, have been completed and shipments will be resumed. With the mill closed, repairs were made underground—retimbering the shaft and one or two drifts. It is thought that No 2 shaft will be sunk deeper to get under the ore shoot dipping to the northwest. Magnetic separators and table concentrators are used in the mill, making a clean product of lead, iron and zinc. The zinc ore is then passed over driers and then the magnetic separator is used, producing two commercial products—iron sulphides carrying the precious metals and a high-grade zinc. In the changes made during the repairing the ball grinders were taken out and Huntington mills put in. Six are set up.

The east end of Fryer hill, at Leadville, is active, says the Carbonate Chronicle. The Fitzhugh mine has resumed under lease to T. Kyle and R. B. Estey, who are opening it up at the 452-foot level. It is necessary to drive a drift 83 feet to reach a known ore body.

OURAY COUNTY.

Near Ouray a fifty-ton mill is going up at the Bob Tail mine, which is expected to be in operation by October 1st. The 14-foot ore body is showing values in gold and silver.——Meadville, Penn., men have leased the Yorktown lode in Red Mountain district, and development work has been started.——Three shifts are driving the tunnel in the Governor mine, and it is expected the gold-bearing vein of the upper workings will be cut this week. The tunnel is in 690 feet and the silver-bearing vein found in the upper workings has already been cut. Should the body of low-grade ore prove as large as in the upper workings, they propose to build a mill. The compressor and boiler, which were moved by a snowslide last winter, will be replaced on the millsite.——The Treasury tunnel is shipping ore.

SAN JUAN COUNTY.

A company, with F. C. Weiser of Nebraska as manager, has been organized to acquire mining territory in Ice Lake section, near Silverton, and last week bought the Emma group of mines for $40,000 The Emma group is in Ice Lake basin, between the Golden Horn mine and the fork of South Mineral creek. The sale included a stamp mill and water right and other mill sites.

SAN MIGUEL COUNTY.

Robbins & Field, who have a lease from the Smuggler-Union M. Co. on all the dumps at the Sheridan mine, in Marshall basin, near Telluride, started their 10-stamp mill last week and are treating twenty-five to thirty tons per day. It is built close to the dumps and the ore is hauled by wagons. Twenty men are at work. The average value of the ore is said to run $10 per ton.

SUMMIT COUNTY.

(Special Correspondence) —The Ten Mile-M. & L. Co. have 179 acres, and the ore shoot is supposed to run a distance of 2600 feet on their ground. They have been operating two and one-half years and recently struck a good body of ore. They are now taking out twenty-five tons of ore per day and shipping to the Leadville smelter. They are crosscutting at present. When they commence stoping they will be able to produce seventy-five tons per day. The ore body is 5 to 7 feet thick and averages $22 per ton. H. M. Shepard, manager of the company, is unwatering an old shaft on the property to take out some ore left there in 1893, which they were unable to get out at that time. As soon as the task of unwatering this shaft is accomplished, it is the intention of the company to install an air compressor for supplying air for both shafts. Sixteen men are employed at present. F. Hurd is secretary and treasurer.

Robinson, Aug. 25.

TELLER COUNTY.

The Mountain Boy M. Co., operating on Raven hill, Cripple Creek, has secured additional working funds and resumed sinking the main shaft. It is intended to continue to depth of 400 feet. A level was extended at the 150-foot point and considerable development work done, but it was found that depth was needed. The territory of the company will be cut by the Ophelia tunnel at depth of 800 feet.

E. S. Johnson of Colorado Springs, sole owner of the Blue Bird mine, on Battle mountain, near Cripple Creek, has decided to equip his property with a steam plant good for from 2000 feet, says the Gazette. The plant will be similar to that in operation over the main shaft of the Vindicator mine, but with the addition of heavier boilers. Johnson has developed the mine to depth of 1350 feet, having opened a number of veins in ore all the way down. The principal ore deposits, however, occur below the 1000-foot point.

R. Young of the Quentin Investment Co. of Denver says the Calera M. Co has taken a bond and lease on the Colorado mine, ¼ mile from the Calera mine, in Cripple Creek district. They will increase developments.

The Savage G. & C. Co. says the monthly report of the work done by Lessee J. D Rankin, operating the Gold King claim on Gold hill, Cripple Creek, shows the lessee will put in air drills and will operate the mine, carrying out development work in the Good Will tunnel, which cuts the property at depth of 600 feet. He will crosscut from the tunnel 250 feet to open the vein at 600 feet.

Lessees Grant & Hart, operating on the Currency claim, on Beacon hill, Cripple Creek, have sunk the shaft to a depth of 110 feet and are drifting on the vein, which is reported showing good values. Drifts have been run 30 feet each way—east and west—from the bottom of the shaft, and an ore body 3 feet wide has been uncovered. At the present time they are operating a whim, but as soon as the ore body warrants they will put up a plant of machinery.

The Globe cyanide mill, near Cripple Creek, is treating an average of fifty tons of ore per day.

IDAHO.

BLAINE COUNTY.

The Gold Star hoist and mill, owned by H. R. Plughoff and H. Allen, were burned last week; loss, $30,000; insurance, $12,000. The property was 14 miles from Hailey.

BOISE COUNTY.

In Deer Creek district, near Idaho City, the Big Bear and Bed Bug claims were bonded last week to G. E. Spencer et al. for $50,000, and development work will be started next week.

IDAHO COUNTY.

It is reported a group of seven quartz and four placer claims in Thunder Mountain district, near Roosevelt and near the headwaters of Profile creek, have been taken over by Lucas & Zsenk of St. Louis, Mo., and W. J. Evans of Terre Haute, Ind., for $100 000.

A 2-stamp mill will be put in on the Lucky Lad, an extension of the Big Buffalo mine, in Hump camp, says H C. Beattie of Seattle, Wash. The plant will be put in to test values. The property is developed by open cuts to 50 feet deep, and the ledge is 27 feet wide. A steam hoist has been set up. The property is owned by the Buffalo Lake Co., of Seattle.——There are 95 men at work on the Jumbo, 30 on the Crackerjack, 4 on the Hamilton, 16 on the Big Buffalo, 6 on the Buffalo Chief, 12 on the Mother Lode, 20 on the Concord and 15 on the Atlas mines.

G. Brant, of the Brant M. & M. Co., near Roosevelt, says they propose to build a stamp mill this fall.

LEMHI COUNTY.

The Lemhi M. Co. is to be incorporated, having taken over the Ramey mines on Silver creek and the Vulcan group of nickel-cobalt claims at the Meadows on Blackbird creek, near Salmon City. Manager W. P. Carter has started development upon both properties. The Ramey mines consist of five quartz and seven placer claims, carrying gold. The company will sink a shaft on the main vein, and will put up hoisting works.

OWYHEE COUNTY.

R. C. Facer, manager of the Golden Opportunity M. & M. Co., operating near Silver City, says work has begun. His company owns fifteen claims in Sugar Loaf district, and the ledge is 11 feet in width, averaging $5 per ton in gold.

SHOSHONE COUNTY.

(Special Correspondence) —The lower crosscut of the Snow Storm property will reach the lead September 1st and will be 1850 feet long. It will tap the vein at a depth of 1160 feet. The upper crosscut, which was completed about fifteen months ago, opened up a 40-foot lead of copper carbonates which will average 4½% copper with a by-product of 6 to 10 ounces of silver.

Superintendent Roof of the Reindeer says the 800-foot crosscut on that property will be completed September 1st. At the face of the preliminary tunnel was exposed a vein of good concentrating ore, 18 feet wide. The ore is chalcopyrite, carrying a good by-product of silver.

The new slime plant of Larson & Greenough at Mullan will soon be in operation. The object of the management is to retreat the tailings and debris from the slime machinery and floors of their 900-ton concentrator. The plant will have 500 feet of settling surface. Water power will be used.

Mullan, Aug. 24.

Wardner reports say it is expected that the electric power brought from Spokane, Wash., by the Washington Water Power Co. to operate the mines of the Cœur d'Alenes will be ready for the properties of that section by September 1st. The equipment is in place in the transforming station of the Silver King mine, the Empire State-Idaho mill at Sweeny, the Bunker Hill & Sullivan and the Last Chance mines. The men stringing the wires are between Kingston and Sweeny. The crew, although somewhat smaller than formerly, is making rapid progress and will undoubtedly have the power ready for some of the stations by September 1st. The electricians placing the transformer equipment are at the stations of the Tiger-Poorman, the Mammoth, the Standard and the Hecla mines. The Frisco and the Hercules are the only mines of the producers outside of Mullan that will be without the power. The Hercules Co. is said to be considering the installation of a complete electric plant. The total horse power received by the mines will be about 4000. Of this amount the Tiger-Poorman will have the greatest—1200—and the rest is divided as follows: Standard, 1000; Bunker Hill & Sullivan, 364; Mammoth, 350; Silver King, Last Chance, Hecla, Empire State-Idaho mill, 200 each. Some of these mines have water or steam power, which will furnish part of the required power.

Manager E. P. Spalding of the Monarch M. Co., driving the Monarch tunnel, 5 miles east of Murray, says the tunnel is in 2300 feet and progressing at the rate of 50 feet a week. It was started a year ago. According to the survey it will have to be driven 600 feet farther to get under the tunnel and into the ledge which has the showing of ore near the surface. It will then be 1400 feet below the upper works.

A compressor plant and a 200-ton concentrator are to be put in at the Highland Chief mine on Pine creek, near Wardner, says C. W. Stanton of St. Paul, Minn., who is part owner with F. J. Meyst of Minneapolis and C. C. Whitney of St. Paul. The foundations of the mill will be laid out so that it can be readily enlarged to 400 tons.

MICHIGAN.

HOUGHTON COUNTY.

Last week fire destroyed the A shaft house at the Atlantic mine, south of Houghton; loss $40,000, fully covered by insurance. The engine house was not damaged. This month's production will be slightly curtailed, but the number of men will not be reduced. Hoisting will continue through the other shafts. Below the collar the shafts will not be damaged.

MISSOURI.

JASPER COUNTY.

The Sarcoxie M. & D. Co. has abandoned its mine and lease east of Sarcoxie (formerly the Sangamo), and has begun sinking on an adjoining lease, known as the Boyd lease, where three drill holes have shown good ore. The company intends to move its mill as soon as its shaft is down to mineral.

The Hayseed mine, north of Joplin, is drifting into ore, says A. Myers. Samples average 20% zinc.

Joplin reports state that the powder famine last week closed down 10% of the mines and more will close down unless the situation is relieved.

LAWRENCE COUNTY.

The John Bull mine and plant, near Aurora, is expected to be in operation next week.——C. Porter & Co. are unwatering the Jack Rabbit mine, and expect to get to work in the ground next week.

J. Hale & Co. are drifting into a good body of jack at their mine south of the Ozark range, near Aurora.

NEWTON COUNTY.

M. L. Ward & Co., who have a four-acre lease at Saginaw, are sinking a shaft which is down 80 feet. At 90 feet the drill showed lead ore for 9 feet which they expect to reach by Sept. 10th, says B. C. Davies, superintendent.

MONTANA.

BROADWATER COUNTY.

Members of the Chicago Electric Light Co. of Chicago, Ill., have bonded the New Era, Vulture, Switzerland, Little Annie and Sitting Bull claims in Park district. ——The Sparta M. Co. has been incorporated by O. Sparta of Hassel and G. Hays, H. Rickards and J. Hibbard of Helena, to work the Bedford Nos. 1 and 2, the Bullion, Gray Eagle and Mammoth claims in Park district. There is a mill and water right with the property. A concentrator and cyanide plant will be built.

FERGUS COUNTY.

At the sapphire mines at Yogo the New Syndicate Co.'s mines have only sixteen men employed at present, says C. T. Gadsden, superintendent. Mining has been suspended temporarily to permit sluicing of the large amount of matrix that was extracted from the mines during last winter. Most of the men employed are sluicing, but a few are making repairs and preparations for resuming mining next month. The first development work will be drifting on the vein from the bottom of a 100-foot shaft. Two dams for holding the tailings from the sluice boxes have been built this summer.

D. J. Burr has bought a one-fourth interest for $1500 in three claims in North Moccasin district, near Lewistown, being the Good Luck, Handicap and Old Flint Rock. They are on Dog creek, between Plum creek and the Barnes-King group.

B. F. Lindsey of Kendall has bought a one-half interest in a group of claims comprising the Gray Hound, Black Bird, Sweepstakes, Blue Bird, Triumph, Troy and Mendota, one-half mile from the head of Plum creek and one and one-half mile from the Kendall mill. Considerable work has been done on them and the ore shows gold values.

The Surprise group, in the Judith mountains, near Lewiston, has been bonded to A. P. Pendleton for the Judith M. Co. for $17,000, says the Argus.

FLATHEAD COUNTY.

W. A. Hillis, N. R. Burlingham and A. Davidson have bonded the Batcheler group of claims in West Fisher district, near Cabinet, for $30,000. There are seven claims in the group and they are on Blacktail mountain.——The A. K. Co. are running their mill on ore broken earlier in the season from the Gold Bug ledge, says the Western News. The tunnel is being driven ahead in the Gold King. When the surplus ore is run out more miners will be put to work and stopes opened, says Manager S. J. Morris.

A strike of ore is reported at the Illinois & Montana G. M. Co. mine in West Fisher district, near Cabinet. The ore shows free gold. It is intended to put a mill on this property this fall.

GRANITE COUNTY.

The Crescent G. M. Co., operating on Stony creek, 20 miles west of Philipsburg, is putting in an air compressor plant at the mine, which will be operated by water power from Stony creek. The main tunnel is in 1020 feet and will go to 1800 feet. E. L. Christensen of Ann Arbor, Mich., is manager.

The Willow Creek M. Co. was organized at Philipsburg last week to develop and operate a group of claims on upper Willow creek. The officers are J. H. Grant, A. H. Wahl, T. J. Haugeberg and D. Olson, who is manager.

A number of lessees are at work on the Nancy Hanks mine at Garnet, owned by S. Ritchey. On the Cascade, another of Ritchey's claims, which adjoins the Nancy Hanks, a tunnel is being driven to tap the Nancy Hanks vein and is in 530 feet. It is expected at 100 feet farther the vein will be cut ——Crawford, Mueller & Baker are leasing the International mine of the Mussigbrod group and are taking out ore.

L. U. Loomis, of the Gold Reef M. Co., operating on the south fork of Boulder creek, 7 miles northeast of Philipsburg, says development work will be increased. He has twelve men at work building a wagon road up South Boulder creek to the mines. Loomis last week bought five adjoining claims—the Mayflower group—which gives the company a tract of 160 acres, with good mill site and a spring flowing 75,000 gallons of water per day.

JEFFERSON COUNTY.

The Lincoln C. M. Co. has been incorporated by J. A. Talbot, P. Mullins, R. B. Smith, J. F. Finlan, J. B. McClernan, W. Y. Pemberton of Butte and T. H. Carter of Helena. The company has acquired a group of quartz claims in Little Boulder district, 12 miles from Boulder. Development work will be started.

G. H. Kent of Helena has a lease and bond on the Mollie McGregor mine near Basin for $50,000 and for eighteen months.

LEWIS AND CLARKE COUNTY.

M. Malm of Cleveland, Ohio, who is interested in the Yellow Jacket properties, 4 miles from Helena, says he is preparing to resume work in the mines and mill.

The Drlebert mill, in Dry Gulch, 4 miles from Helena, has been put in operation.

The Gold Ridge M. Co. has been incorporated by H. Klein, F. K. Turner, E. C. Day, J. A. Walsh and J. O. Briscoe, of Helena. They will develop and work a group of seven quartz claims and eighty-three acres of placer ground and 1500 miner's inches of water in the Prickly Pear river, near the Big Indian mine. The Northern Pacific and the Great Northern railroads and the line of the Missouri Power Co. all run through the placer ground. The company will start work next week, and will put up a 100-stamp mill at the mouth of Jackson creek on the power line, bringing the ore from the mines by a wire tramway, says the Inter-Mountain.

MADISON COUNTY.

The Clipper mine, near Pony, is closed down.

At Brandon, near Virginia City, the mill and smelter of the Bismarck-Nugget Gulch Con. M. Co. are ready, awaiting completion of the power plant. The mill has capacity of 100 tons per day. It is equipped with Blake crusher, roughing rolls, to which is attached with automatic feeder two sets of finishing rolls, two trommels, hydraulic classifiers, two four-compartment jigs, settling tanks and table concentrators. The ore is conveyed from the mines, a distance of 1⅛ mile, with elevation 800 feet above the mill, to the mill by aerial, double-rope tramway having capacity of 500 tons per day. The tram is supported by twenty-one towers, varying in height from 16 to 45 feet. At the mill the ore is automatically dumped onto grizzly bars, from which it is automatically fed to a crusher. The concentrates are elevated automatically to the drying floor of the smelter, from which they go to the charging floor by gravity. The furnace is a fifty-ton water jacket lead furnace. An electric road connecting the company's mill and smelter with the N. P. railway at Sheridan will be built.

MISSOULA COUNTY.

Vermillion reports state that the concentrator and nearly the entire plant of the Kentucky-Vermillion M. & Concentrating Co. was destroyed by fire last week. The loss is estimated at $125,000, with $30,000 insurance. The property was owned by Spokane, Wash., men, being E. J. Dyer, E. H. Belden, J. Lawyer and J. E. Branscombe.

PARK COUNTY.

Manager Byrne of the Sheep Mountain M. Co., near Cooke City, says arrangements are being made to build two mechanical roasting furnaces.

POWELL COUNTY.

The Missouri & Montana M. Co. has bonded for $25,000 two claims on Nigger Hill, near Elliston, called the Whitetail and No. 2. They have 4 feet of gold-silver-lead ore, averaging $25 per ton, says the Inter-Mountain. The company has three shifts sinking a shaft and driving a tunnel, and shipping ore is being taken out.

NEVADA.

ESMERALDA COUNTY.

J. H. Rae, of Dayton, has bonded the Lottie group of claims in Garfield district for $3500. The ore carries values in silver, gold and lead. The claims are 6 miles from the C. & C. railroad. Developments will be started.

HUMBOLDT COUNTY.

The Zelda mine, 30 miles southwest of Lovelock, started up last week with sixteen men.

LINCOLN COUNTY.

The strike situation at Searchlight, after two and a half months, seems to show little or no change. The owners and operators are still in Los Angeles, Cal. Contract work is in progress on the Cyrus Noble; the Ione is working a few men, paying the union scale of wages, and the New Era is building a mill. In general, the union is said to be sanctioning all prospect and development work, producing properties alone being under the ban.

The Wagner Bros. group at Knoh Hill, near Searchlight, have been sold to F. L. Winters, J. B. Anderson and F. Siegel for $5000. It consists of the Daisy, Daisy Bell and Oakland and the Daisy Bell mill-site. There is a small stamp mill on the ground. The main difficulty in the past has been lack of sufficient water.

NYE COUNTY.

(Special Correspondence).—In the Charm mine here, owned by Martin Murray, president; Dennis M. O'Sullivan, vice-president; Paul Desmond, secretary; John S. Merrill, treasurer; W. R. Whittier and N. N. Wilson, an assay of ore, 8 feet from the surface, this week showed gold, 15.35 ounces, $315; silver, 40c.

Butler, Aug. 24.

The Atwood M. & D. Co. has leased to the Inman Co. two claims of their group at Atwood, near Tonopah.

At the Ohio-Tonopah mine at Tonopah the air compressor plant and machine drills are in operation.——At the Tonopah & California mine the main working shaft, on which sinking was resumed August 1, has been sunk 25 feet below the 450-foot level. They are working eighteen men, says President Blythe.

The Montana-Tonopah M. Co. at Tonopah reports a recent shipment of sixty-three tons of ore which netted $14,428.

At the Rescue mine, near Tonopah, the pump was started last week, the shaft unwatered, and sinking has resumed.

The McNamara mine at Tonopah closed down last week, having reached a depth of 500 feet. Superintendent A. P. Canters says it is expected the closedown will be of short duration.

STOREY COUNTY.

The fluming of the tailings near the Ward tunnel through the boxes to the Butters' cyanide plant, near Virginia City, has begun. Little trouble has been experienced in carrying the tailings a distance of 3 miles with the flow of water available. The new tanks being put in at the plant are about completed.

All the Comstock mining properties at Gold Hill and the middle mines, as far north as the Savage, inclusive, have entered into an agreement to put the Foreman shaft, which was damaged by fire last spring, in repair from its collar down to the level of the south lateral branch of the Sutro tunnel. The Foreman shaft being a downcast, the ventilation of all these mines will be greatly improved, says the Territorial Enterprise.

At a meeting of the presidents of the following mining companies operating on the Comstock, held in San Francisco last week, the Ward Shaft Association was organized: Gould & Curry, Savage, Challar, Potosi, Bullion, Exchequer, Alpha Con. and Julia Con. C. Hirschfeld is president, J. W. Twiggs secretary and L. M. Hall of San Francisco, Cal., superintendent. The object of this association is to put the Ward shaft in repair and resume prospecting work in the lower levels of the mines mentioned. This will involve lowering the water in that part of the Comstock. It is expected operations will begin September 1st. The Julia Con. and Bullion companies own the Ward shaft, but they have agreed to grant a perpetual right to work through the shaft to the other companies.

WASHOE COUNTY.

There are 125 men on the payrolls of the mining companies in Olinghouse canyon, near Wadsworth.

WHITE PINE COUNTY.

The White Pine C. Co. has bonded the Last Hope and Columbia copper mines, which join the Ruth group on the north, near Ely, for $9000. M. L. Requa of San Francisco, Cal., is manager of the White Pine C. Co.

NEW MEXICO.

COLFAX COUNTY.

The 50-ton cyanide plant of the Thelma M. Co., near Baldy, is being overhauled preparatory to resuming.

GRANT COUNTY.

T. N. Stebbins, having bought the Casino mine 9 miles southwest of Silver City, is doing development work. Grading for the mill is in progress, and it is thought the cyanide process will be also added.

LUNA COUNTY.

J. Allard and D. Michael of Deming have secured the McComus group of claims in the Florida mountains on which they intend to start development work.

SIERRA COUNTY.

Work is being resumed on the Ready Pay mill at Hillsboro. Operations had been delayed by non-arrival of machinery. The pumping plant is working.

D. S. Miller of Lake valley and L. Sly have bonded their partners' interests in the Log Cabin mine at Tierra Blanca, says the New Mexican.

SOCORRO COUNTY.

M. Thomas reports having men at work opening up a copper prospect near San Acacia, 7 miles from the railroad and the Rio Grande river. The property is the Jerome group in San Lorenzo mining district, in Magdalena mountains. A shaft has been sunk to depth of 60 feet and a drift run out 40 feet, showing a 6-foot vein of copper ore, assaying 20% copper and $5 in gold per ton. The vein is said to be between walls of porphyry and limestone.

TAOS COUNTY.

At Anchor, near the Red river, the Cashier M. & M. Co. is making arrangements to develop a group of four claims, and one lead is said to be 90 feet wide. Over 450 feet of shafts and crosscuts are made. The company has started a tunnel that will cross the leads at depth of 300 feet, and which will also drain the mine of surface water, which has given some trouble in the past. A mill to treat 300 tons of ore a day will be built, says the New Mexican.

OREGON.

BAKER COUNTY.

A half interest in the Leonard, Emma W., Gold Dollar and Gold King claims, in the Greenhorn mountains, near Sumpter, has been sold to C. M. Johnson of Gelser for $2,000.

T. W. Davidson, manager of the Don Juan mine, near Sumpter, says he has started unwatering the mine, and development work will be resumed next week. The Don Juan is owned in Bay City, Mich.

Superintendent J. E. Reed of the Auburn Deep M. Co., at Auburn, states the shaft being sunk is down 209 feet, and it is thought to be near bedrock.

It is locally reported from the Stices Gulch placers, near Sumpter, that opals have been discovered at the diggings.

Arrangements are being made for a 10-stamp mill on the Snow Creek mine, Greenhorn district, near Sumpter, says Manager F. D. Smith. The mill will have a steam plant, ten stamps, three table concentrators, and will be near the mouth of the Zelda tunnel.

COLUMBIA COUNTY.

W. A. Gray, superintendent of the Polar Star and Dixie Queen mines, near St. Helens, says they have a tunnel driven on the ledge of the Polar Star for 600 feet and on the dump are 2500 tons of ore which will average $25 per ton. The group consists of twenty-one claims, and several ledges show on the surface. Ore is being blocked out for the stamp mill which it is proposed to build. A chlorination plant will also be used. On the Dixie Queen men are driving a tunnel which is opening up a ledge. This property is also owned by Portland men.

CROOK COUNTY.

After two years' idleness due to litigation Cartwright & Edwards, owners of the Oregon King mine, will resume operations this fall. The Oregon King is near Hay creek. They propose building a 20-stamp mill, so that bullion and concentrates only will have to be shipped out. The mine is down to depth of 500 feet and partly filled with water. A pumping plant will be put in.

DOUGLAS COUNTY.

I. D. Davidson of Portland, treasurer of the Gold Hill & Bohemia M. Co, near Bohemia, says work will be started September 1 on their Wall Street group. Later a mill will be erected. The ore is copper, gold and silver.

The Oregon Securities Co. has bought the Broadway group of mines, adjoining the Champion basin, near Bohemia. This gives the company a continuous strip of 3 miles of ground. L. Y. Keady, C. H. Thompson, A. W. Goddard, J. B. Glover and J. H. McNicholas of Portland are interested. Improvements and increased developments are under way. There are forty men at work on a 30-stamp mill (the combining of the three 10-atamp mills that have been on different parts of the property). These mills have been idle for some time owing to the scarcity of water, but, combined, will be operated by electricity, generated by water power. A gravity double-track tramway will convey the ore to the mill. Air drills will be used in development, and a tunnel 1400 feet long will be driven. Three saw mills are running steadily on the company's property, says the Portland Telegram.

It is reported M. O. Warner of Eugene and J. D. Heard of Medford are arranging to build a smelter at Bohemia, work to begin next month.

JOSEPHINE COUNTY.

J. M. Marks of Seattle, Wash., has a bond on the Gold Mining King group of claims and will build a mill thereon. He will also put in a pumping plant and other machinery.

Two carloads of hydraulic pipe for the Simmons-Cameron placer of Waldo are on the ground, says Manager J. T. Logan. The pipe is in three sizes, 24, 20 and 18 inches in diameter. Last season's work gave satisfactory results with the hydraulic elevator in operation. This year he intends to raise the gravel to height of 34 feet.

The Galice Greek H. M. Co., on Galice creek, near Grant's Pass, has men at work digging ditches and building the flume, as well as operating the sawmill and building a reservoir. The sawmill is cutting 5000 feet of lumber from fir and

pine timber. This lumber could not he bought on the outside for less than $30 per 1000 feet, but the company operating its own mill cuts it for $7, says Manager A. B. Cousin. A rock-filled dam 22 feet high has been built at the head of the main ditch. Besides the flume, which will carry the gravel, there will be five giants at work.

LANE COUNTY.

S. R. Jones of Oregon City reports the building of a 40-stamp mill on the Lucky Boy mine, near Blue river. A cyanide plant will treat the tailings.

MALHEUR COUNTY.

T. A. Kelly and J. T. Lennox of Lynn, Mass., have leased the Basin, Star and Sulphuret claims, in Humholdt basin, 6 miles from Malheur City. The bond calls for $35,000 if a sale is made.

MARION COUNTY.

A. W. Dawes and H. H. Lempker of Mill City, directors of the Lewis & Clarke M. & M. Co., with headquarters at Silverton, report work progressing on their holdings on a fork of the North Santiam river. The ore carries gold, silver, copper and lead. The group consists of three claims near Elkhorn. The company is preparing to build a mill, which it is intended to have in operation next summer.

MULTNOMAH COUNTY.

It is reported W. A. Clark of Butte, Montana, has decided to build a smelter at Portland, chiefly for smelting the ores of his lead mines in Cœur d'Alene district, Idaho.

SOUTH DAKOTA.

CUSTER COUNTY.

The Crown Mica M. Co., near Custer, is preparing to resume work, when shipments will he made.——The Black Hills Porcelain, Clay and Marhle Co. is planning to reopen its properties. The Inter States M. Co. is working steadily and the Grantz is also.

LAWRENCE COUNTY.

A. Fillion, superintendent of the Pluma G. M. Co., says his company has crosscut the ledge on the 300-foot level for a distance of 120 feet and is still in ore, which averages $3.50 per ton in gold.

The Lexington G. M. Co. is dropping ten stamps in the old Highland Chief mill of Spruce Gulch, 2 miles from Deadwood. The company has added an engine and a larger boller. The assay office is being enlarged. The company is experimenting with a process for treatment of sand and slimes without separating.

Dorr & Wilson have hegun huilding their cyanide mill near Terry. It will he on the slope a short distance from the mine. All ore will be moved by gravlty. The machinery will consist of a number of Chilian mills for crushing ore in a solution, the power to he supplied from the Belt Electric Light & Power Co. Water will he pumped from some of the old workings on the ground.

The grade is finished, foundation work under way and lumber is on the ground at the site of Lundberg, Dorr & Wilson's cyanide mill at Terry, says the Black Hills Revlew. The new plant will he ready to run this fall. It will employ electricity for power entirely and will crush the ore in Chilian mills.

PENNINGTON COUNTY.

The cyanide plant huilt at Pactola for extracting values from fine sands of placer gravel is a success. The system is to save the free gold, first, hy amalgamating plates, and then cyanide the tailings, which saves a large percentage of the values. The company expects to enlarge the mill's capacity.

It is reported the Horseshoe M. Co. propose starting up their smelter at Rapid City hy September 10th. It has two furnaces.

UTAH.

GRAND COUNTY.

The litigation involving the Paradox-La Sal mines, near Basin, is reported settled and operations will be resumed.

L. Taylor, manager of the Big Indian and Blue Jay mines, near Moah, says at Big Indian the ore bodies are to be opened up as soon as equipment is put in, while at the Blue Jay they are drifting on the ledge, showing high-grade copper ore.

W. A. King and F. Moorehouse of Salt Lake City, of the International G. & M. Co., operating in Beaver hasin, near Basin, in the La Sal mountains, report their intention to go ahead with work in the Chimney Sweep and Fortune Teller claims, where they have a mineral showing high-grade ore. A shaft is heing sunk on the Chimney Sweep in a vein of copper ore, and drifts will be run on the Fortune Teller.

The Interstate Co., in Gold Basin, near Basin, are getting machinery on the ground for their mill, which will be a chlorination and cyanide plant, says the Trihune. The ores will mill $11 per ton gold. They expect to have the mill in operation by Oct. 1.

IRON COUNTY.

The anthracite deposits at New Harmony, 8 miles from Iron mountain, near Kanarraville, are being opened up hy Superintendent R A. Kirker. In the main tunnel the work has passed through three veins, two of which show 4 feet of coal. The veins dip at an angle of 70°, and with a tunnel can be opened up to deptb of 600 feet, says the Tribune.

JUAB COUNTY.

The main shaft on the Centennial-Eureka mine, at Eureka, is down 1800 feet bolow its collar, and at that point another level will be estahlished, says Manager C. E. Allen. Meanwhile 200 tons of ore is coming daily from tbe mine to the furnaces of the United States smelter. Tho 1800-foot level is 2500 feet helow the apex of the zone, which rises 700 feet above the collar of the shaft, says the Tribune.

The Carisa ore shoot is reported opened in the Victor mine, near Eureka, this time on the 500 foot level, 600 feet south of the raise that was made to the surface. A drift which was being extended to connect with a winze from tbe 400 foot level struck ore, which shows 10% copper, containing twelve ounces of silver per ton.

PIUTE COUNTY.

(Special Correspondence) —A gold strike has been made in the Gold Vein M. Co.'s property in Horse Heaven district, 10 miles from Marysvale. The vein is 9 feet in width, with a pay streak of 5 feet. The property is owned hy Salt Lake and Eastern men and is under the management of G. F. Dalton. The company is putting in extensive improvements and has a large force of men at work.

Marysvale, Aug. 22.

A strike of gold bearing quartz is reported made in Horse Heaven district, 10 miles southwest from Marysvale, hy the Gold Vein M. Co. The ledge is 9 feet in width, and the pay streak 5 feet. The quartz shows free gold. G. F. Dalton of Salt Lake City is manager.

SALT LAKE COUNTY.

After two years' suspension of shipments the Silver Shield mine, near Bingham, is again sending out ore, the tunnel having reached the junction of the cross fissure and main veins.

D. H. Peery & Co. of Salt Lake City and H. Joseph have filed with the State Engineer an application which shall entitle them to use of the waters of Little Cottonwood creek above and east of Alta; the waters issuing from the Bryan tunnel; the waters of Peruvian gulch and those of White Pine creek, the latter all tributary to Cottonwood creek, the same to be used in the generation of power and light for mining and milling purposes. This will afford energy equivalent to 1000 H. P., says Joseph.

The Collins group at Alta has heen sold to J. A. Kirby, A. Colbath and L. A. Jeffs. The group includes four claims and three fractions, lying west and north of the Albion Co.'s ground.

The Falco group of mines, at Bingham, of the Cluster M. Co., has been sold to W. M. Perry and W. H. Walker of Salt Lake City, and with C. A. Falco as manager will he extensively developed. The group is between the Old Telegraph and Dalton & Lark mines.

Work on enlargements at the Highland Boy smelter, at Bingham, was started this week, says Manager R. H. Channing. The enlarging will begin on the main stack, which will he elevated 50 feet or to a total height of 250 feet. Two furnaces will he added.

SUMMIT COUNTY.

The Daly-Judge mine, at Park City, is sending out between 300 and 400 tons of concentrates to the smelters weekly.

Operations have heen resumed at the Corona mine of the Donovan group, near Park City, and sinking is under way. J. Hasson is superintendent.

Superintendent B. E. Hartwell of the East Ontario M. Co., near Park City, reports operations again under way. A hlower is being set up in the tunnel.

TOOELE COUNTY.

The Honorine tunnel at Stockton is being advanced at the rate of 10 feet per day and has been completed to length of 4280 feet, says Superintendent Raddatz.

J. B. McGee, superintendent of the Sacramento M. Co.'s retorts at Mercur, says from 2400 pounds of rock that was reduced on the 17th inst. he ohtained 233 pounds of quicksilver and 1400 pounds of gold-hearing slag, which latter is to he treated in the leaching tanks. With present equipment he says the product of the retorts should average 233 pounds daily.

The Merrill M. Co. has heen incorporated at Salt Lake City to operate near Dugway, in Deep Creek district. It has a group of six locations, on which 400 feet of work has been done, the ores showing values in silver and gold, occurring on the contact hetween the limestone and quartzite. They adjoin the Carrick group. H. H. Green, M. Merrill, J. G. Jacobs, D. McVichie and E. W. Gillette are directors Work is under way.

The hreaking of ground for the Honorine concentrator, near Stockton, has begun, says Superintendent E. J. Raddatz. The tunnel through which the ores are to be dellvered to the concentrator at Buhl, a few miles out of Stockton, has heen driven 4300 feet.

UTAH COUNTY.

C. Barrett of Salt Lake City, manager of the Paraffine mine, at Mill Fork, in Spanish Fork canyon, says a 6-inch hody of wax (elaterite) had been struck. Work was temporarily suspended because of the presence of quantities of gas, which is not a detrimental feature, but must he controlled, says Barrett.

M. J. Stewart of Salt Lake City has hought for $1000 tbe Erma-Fitz-Lone Pine group of claims in Silver Lake mining district.

WASHINGTON.

FERRY COUNTY.

Work will be resumed this week on the Apollo mine, near Republic, says Manager E H. Delhridge.

Superintendent N. Cochran of the Mountain Lion Mine, near Republic, says operations have resumed. He will at first ship 100 tons of ore per day to the smelter.

The Mountain Lion M. Co., operating at Repuhlic, has heen reorganized, witb A. E. Palmer of Spokane and J. M. Gearin, J. A. Cranston and G. Mallory of Portland, Or., as officers. President Palmer says preparations are heing made to increase ore shipments to 300 tons daily. N. Cochran is superintendent. Republic camp has heen shipping 700 tons of ore a week. With the Mountain Lion's increase its output will go up to 2500 tons a week.

Development work is expected to be under way next week on the Knoh Hill and Little Cove mines, near Repuhlic.—— The North San Poil mine is taking out good ore from the south drift on the 125-foot level.

OKANOGAN COUNTY.

C. P. Coey of Rockford says he will start work at the Ore Or No Go group at Wauconda.

STEVENS COUNTY.

J. Borgan, C. Miller, et al., have started work on the Last Chance tunnel, near Northport, which is in 300 feet. They will run 100 feet farther, when shipping of ore will he resumed.

WHATCOM COUNTY.

(Special Correspondence). — Superintendent L. Friede of the Post-Lambert mine, in Mount Baker district, north of Baker, Skagit county, reports shipping their first clean-up of gold, amounting to $27,000, the result of twenty-five days' run of the 10-stamp mill. The mill handles thirty-five tons of rock daily. The mill is of 1000-pound stamps, with concentrators helow plates. A 4000-foot aerial tram connects mill with mine and storage bins for handling an ore reserve. The vein is of quartz from 4 to 5 feet in width, with general strike to the west of north, and dip of 40° to 45° west and into the mountain. The ore is said to carry tellurides and free gold throughout the gangue, though generally contained in a pay streak. The mine has heen developed hy 2000 feet of work, consisting of tunnels, drifts and raises, most all of which have been done in ore. Some stoping has been done to supply an ore reserve for mill.

Tacoma, Aug 26.

WYOMING.

CARBON COUNTY.

Superintendent J. Montague of the Goldwater's Wolverine mine, near Grand Encampment, reports opening up a sulphide shoot for a distance of 15 feet in a drift to the east from the shaft. The drift is being run from depth of 65 feet. If the shoot is of sufficient size the plant of machinery, which is in the upper shaft house, will be hrought down and set on the new shaft.

FOREIGN.

AFRICA.

RHODESIA.

The Beatrice, at Bulawayo, Aug. 5, report July cyanide return: 1100 tons treated, yielding 247 ounces gold.——Geelong Gold, Ltd., July output was: Forty stamps (26 days) crushed 3698 tons, for 1619 ounces ——The Rezende Co. report, Aug. 7: Twenty stamps, running 29 days, crushed 3000 tons, yielding, from mill, 751 ounces, from tailings hy cyanide, 158 ounces; total, 909 ounces fine gold; also, 8 tons concentrates, containing 28 ounces. ——The Transvaal G. M. Estates for month of July are reported at: Mill crushed 5317 tons, yielding 1982 ounces; cyanide works treated 3470 tons for 1322 ounces; slimes works treated 1800 tons for 370 ounces.

TRANSVAAL.

The Cassel Coal Co. July output was 12,434 tons.——The Durhan-Roodepoort G. Co, at Johannesburg, report for month of July: Quartz milled, 5890 tons (40 and 45 stamps, four and sixteen days), for 2943 ounces; tailings treated, 4840 tons, (50 stamps, eight days), for 959 ounces; total, 3902 ounces. The shortage in the stamping power during the month was due to a large number of time expired natives having left, the new ones being unused to the work.——The Lancaster Gold Co. July result was: Fifty-five stamps, running twenty-nine days, crushed 8300 tons, yielding 1990 ounces fine gold; at cyanide works 6379 tons were treated for 1030 ounces fine gold.——The New Primrose Gold July production was 6731 ounces from 120 stamps dropping twenty-nine days ——The Transvaal & Delagoa Investment Co. colliery output for July was 38,500 tons.

WEST AFRICA.

The Ashanti Goldfields Co., Aug. 3, report: July crushings from Obuassi mine, 1710 tons of ore for 4000 ounces gold. Development cahle not received. —— The Ashanti Sansu mines July crushing was 1680 tons, producing 1630 ounces gold.

AUSTRALIA.

NEW SOUTH WALES.

The Lloyd Copper Co. production for July was 197 tons copper. They report the water supply now assured for more than twelve months ahead.

The Malacca Diamond Co. at Copeton, August 6th reports 102 loads washed, producing 132 carats diamonds and 2932 pounds of tin.

QUEENSLAND.

At the Day Dawn Block & Wyndham G. M. Co. at Charters Towers, for four weeks ended August 1 the battery crushed 2930 tons for yield of 1274 ounces of gold, valued at £4500. At the company's works at Burdekin river and Old Wyndham mills 3780 tons of tailings were treated for bullion valued at £3000.

SOUTH AUSTRALIA.

The Northern Territories M. & S. Co. report August 6th at the Mount Ellison mine. Total depth of shaft 120 feet. At the smelting works excavations for buildings, furnaces, flues and stacks are completed and water jacket smelting foundations finished, with iron work going up. Reverberatory furnaces and brick work are under way.

BRAZIL.

The St. John Del Rey mines report gold production during the month of July at £24,200, the yield per ton heing 0.59 ounce troy.

BRITISH COLUMBIA.

BOUNDARY DISTRICT.

The number of men at the Athlestan mine, a mile from the Winnipeg mine, in Wellington camp, has been increased, and it is expected shipments of ore to the Sunset smelter will be larger in the future, says Superintendent Oxley. The ore must be hauled in wagons to the Winnipeg spur of the C. P. R.

EAST KOOTENAY DISTRICT.

The mines at the three collieries of the Crow's Nest Coal Co. for the month ending Aug. 1st show a steady increase over all previous months, says the Rossland Miner. It is estimated that had there heen no hreak the total output would have heen 10,000 tons greater. The figures for the camps are as follows:

	Tons.
Coal Creek	24.793
Michel	28.569
Morrissey	18,10J
Total	71,462

The total for June was 71,253 tons.

The coke shipments for the month were:

	Tons
Fernie	8.696
Michel	7,639
Total	16,335

This also is on the increase. Work is going ahead at Coal Creek in No. 4 and No. 5. Coal has heen struck in No. 4 at 50 feet and in No. 5 at a short distance. The seam in No. 4 is 20 feet thick and No. 5 is 8 feet thick.

The Gold River M. & Power Co. has been formed in South Dakota to operate near Fort Steele. Manager D. S. Guinter says work will start this week on the Bull river water power; a surveying party will run lines for a ditch or flume and preparatory work will hegin on several placer claims which have heen leased from the government.

NELSON DISTRICT.

P. White, superintendent of the Wilcox

mine, 7 miles from Ymir, say he is arranging to add a 10-stamp mill to their equipment. At present there is a 2-stamp mill in operation. The tunnel is now in on from 8 to 9 feet of profitable milling ore, and the property is in the best shape it has ever been for turning out a large tonnage.

ROSSLAND DISTRICT.

A. MacLean of London, Eng, a director of the company, says there is no intention of closing down the Velvet mine, near Rossland, permanently as reported. It will resume when Superintendent Gray returns from England, about Oct. 15.

Underground work is under way at the Nickel Plate mine near Rossland. The difficulty between this mine and the Center Star, through the excessive seepage into the Center Star workings, is to be obviated by the construction of brick bulkheads at the western terminals of Nickel Plate drifts on the 490 foot and 600-foot levels.

SLOCAN DISTRICT.

Manager Garde, of the Payne mine at Sandon, says he has started building a flume from No. 8 tunnel on the McGuigan side of the mountain to tap the stream and secure a sufficient supply of water for mill power. The length of the flume will be 6200 feet and assures water for all purposes the year round.——There are fifty men in the Payne mine and twenty-seven in the mill. The operation of the zinc plant will be delayed several weeks, owing to the damage done the magnetic separator by the floods in Missouri while it was en route.

The Spokane company owning the Big Bob group, near Slocan City, will start work this week, after a period of inactivity. Development work is said to show two ledges, one of gold and copper ore and the other of silver and lead. Work has started on the Legal Tender mine in the same district.

VANCOUVER ISLAND.

A number of prospectors operating on the west coast of Vancouver island have gone to Ingersol river, which flows into Quatsino sound from the south, says the News-Advertiser. A lead of magnetic iron oxide carrying gold values has been found.

The Western Federation of Miners, with headquarters at Denver, Colo., has lost the strike of the coal miners at Cumberland against James Dunsmuir. Despite the high prices for coal he has preferred to let the mines lie idle nearly six months rather than recognize the Federation. W. Moore of the Federation is said to have reached Nanaimo last week from Denver with relief funds for distribution if the miners should not agree to Dunsmuir's final proposition. The miners have voted to accept Dunsmuir's terms, and have agreed to return to work on two-year individual contracts. Dunsmuir says he will increase the output of the Cumberland mines from 800 to 1500 tons daily. He will withdraw his colliers Wellington, Tellus and Hera from the San Francisco-Australian route and instead will ship coal by them from Nanaimo to San Francisco, Cal. He is also preparing plans for a car ferry capable of carrying twenty-eight carloads of coal and coke from Comox to Ladysmith and the Crofton smelters to the mainland.

WEST KOOTENAY DISTRICT.

At the Oyster-Criterion mill in Lardeau section, near Ferguson, the rock crushers and mortars are in place The compressor and power house are being roofed in and cables for the tramway are being strung from the upper terminal to the mill.

G. Stead, who owns the Lucky Jack, Horseshoe and other claims near Trout Lake, has bought the Alice mine in same section.

CHILE.

The Copiapo mines at Copiapo, in Atacama province, report the July production at 1000 tons of copper ore, averaging 16%.

The Santa Rosa Co., near Iquique, gives the production for July from the properties of the company at $11,500, and from leased properties $3500.

KLONDIKE.

The Ladue quartz mill, near Dawson, is being dismantled and the machinery removed. A number of quartz ledges were found on El Dorado and other creeks, carrying some free gold. Two quartz mills were built and the Yukon Government asked to establish a mill which would grind quartz, either free or at minimum expense. Later developments are said to show that quartz mining will be impracticable unless conducted on a large scale with cheap labor. Manager Bottsford, of the Ladue M. Co., says the mill is being taken down because the Dominion Government charges $5 per foot frontage for the land the mill occupies, besides heavy taxes. The Government declined the offer to buy the mill outright.

MEXICO.

CHIHUAHUA.

Superintendent F. A. Shneider says he is getting the Creel smelter at Terrazas camp in shape for starting up next week. Nine cars of coke have arrived and ore is being taken out.

E. L. Horner of Leadville, Colo, manager, says a company has been organized with Kansas men to take over the Santo Domingo placer mines on the Concho river, which he has under bond for $250,000 gold. Operations are suspended pending this deal. It is intended to put in machinery and have the mines in full operation by Jan. 1.

DURANGO.

At El Cobre mine, near La Trinidad, owned in part by Cushing & Walcup, they are building a matte smelter of fifty tons capacity, which is expected to be in operation next month. E. Bruckhold is manager and has 300 men employed.

SONORA.

The Graphic mine, owned by Captain Fitch, near Magdalena, is yielding zinc ore, 2000 tons having been recently shipped at a profit to Mineral Point, Wis., says Fitch. This ore is said to carry the mineral marionite, previously known only at Marion, Ark.

The mill of the Promontorio M. Co. at Promontorio, in Magdalena district, has been overhauled and operations resumed last week.

PERSONAL.

H H. COHEN, of London, England, is examining mines in Chihuahua, Mexico.

L. S. NOBLE is in Guanajuato, Mex., from Colorado Springs, Colo, examining mines.

W. H. KELLS is manager of the Knob Hill and Little Cove mines, near Republic, Wash.

DANIEL BEST, of the Best Mfg. Co., of San Leandro, Cal., has returned from a business trip.

A D. GASSAWAY, of North Bloomfield, Cal., has returned from a business visit to San Francisco.

A. B CHITTENDEN is now assayer for the 50-stamp mill of the Bayard M. & M. Co., Barstow, Cal.

J. W. PHILLIPS, managing a mill and cyanide plant at Silver City, Nev., is in San Francisco, Cal.

W. S. PETERS, secretary of the Best Mfg. Co., has returned from Monterey to San Leandro, Cal.

F. L. BARTLETT has returned to Denver, Colo, from a trip to the Lake Superior district, Mich.

N. COCHRAN of Rossland, B. C., is superintendent of the Mountain Lion mine, near Republic, Wash.

F. BURNS is in charge of the 240 and 300 stamp mills at the Treadwell mines on Douglas Island, Alaska.

J. J. MCSORLEY is in San Francisco, Cal., from San Andreas, Calaveras county, Cal., on mining business.

J. A. KIRBY, general superintendent of Daly-West mines of Park City, Utah, is visiting at Seattle, Wash.

W. GRAY, superintendent of the Velvet mine, near Rossland, B C, has gone to London, Eng., on business.

W. G. DODD, president of the Union Iron Works, has returned to San Francisco, Cal, from New York.

R. T. PIERCE, superintendent of the Crystal Lake G. M. Co., at Lundy, Mono county, Cal, has gone East.

R. C. FACER is manager of the Golden Opportunity M. & M. Co., near Silver City, Owyhee county, Idaho.

MANAGER G. L. MOATS of the Four Metals M. Co. is in Omaha, Neb., on business, from Salt Lake City, Utah.

WESLEY MERRITT, industrial commissioner of the Santa Fe Railway, has returned from New Mexico to Chicago.

F. LYMAN of New York City succeeds the late T. D. Rand as treasurer of the American Institute of Mining Engineers.

F. P. Sherwood, of the Con. Gold Fields M. Co, of London, Eng., operating on the West Coast, Africa, is in Spokane, Wash.

H. W. NELSON has resigned as superintendent of the Alpine mine near Sumpter, Or., on account of ill health and will go to California.

MANAGER R. H. CHANNING of the Highland Boy smelter, at Bingham, Utah, returned to Salt Lake City, Utah, last week from Montana.

T. H. LEGGETT has resigned as consulting engineer for Neumann & Co., of the Con. Main Reef gold mines at Johannesburg, South Africa.

I. SUTHERLAND of Brunswick, Me, secretary of the Big Creek G. M. Co., has returned from a visit to the mines near Groveland, Tuolumne county, Cal.

J. O. BONE of Tacoma, Wash., is at Nicola, B. C., examining the Western Coal & Iron Co.'s property, 45 miles east of Spence's Bridge, a point on the C. P. Railroad.

W. E. THORNE has gone to Georgetown, Cal., to inspect mining property there and gather ore specimens for the California exhibit at the St. Louis Exposition.

C. L. DIGNOWITZ is in Colorado from Utah and after an examination of his properties in Boulder county will go to Deadwood, S. D., to attend the Mining Congress.

PRESIDENT SHULER AND TREASURER BROWN, of the Chancellor G. M. Co., have returned to Illinois from an examination of their Pacific Coast mining properties.

WM. MAGENAU, until recently located in Guanajuato and Mexico City, is examining mines in the State of Oaxaca, Mexico, and expects to return to the United States shortly.

J. DUNRAVEN YOUNG, director of the Chicago School of Assaying, who has been examining and reporting on mining properties in the State of Washington, has returned to Chicago, Ill.

E R. MORFETT of the Standard Gas Engine Co, San Francisco, Cal., is in Eureka, Humboldt county, Cal, installing two engines (12 H. P. and 30 H. P.) for the Vance Redwood Lumber Co.

L L. TOVEY, Professor of Mining in the University of Tomsk, Siberia, who has been inspecting mining and milling methods in Colorado, is now in South Dakota on his way to New York.

GOVERNOR PARDEE has appointed as California's delegates to the American Mining Congress, at Deadwood, S. D., T. Ewing, D. Murphy, F. W. Braun, H. S. James and W. J. Trask of Los Angeles; F. Rexinger, W. C. Ralston, C. W. Merrill and E. H. Benjamin of San Francisco, and C. M. Belshaw of Contra Costa. The California State Miners' Association and the San Francisco Chamber of Commerce have also named the same parties as their representatives.

Obituary.

E. M. PECK, a Utah mining man, died August 22nd at Gosben, Utah. Deceased was born in Vermont, July 24, 1828 He was a member of the Mormon Battalion and was present at the first discovery of gold at Sutter's mill, California.

J. D. WILLIAMS, a pioneer miner of California, died at his home near Placerville, El Dorado county, Cal, on the 19th inst, of dropsy and heart failure. Deceased was a native of Cornwall, England, aged 78 years. and is survived by one son, a resident of Nevada, and a daughter.

COLONEL CHARLES E. TAYLOR, a prominent mine operator of Denver, Colo, died in New York August 20th. Colonel Taylor was once president of the May-Mazeppa mine near Gunnison, Colo., and was also president of the Mining Exchange a number of years ago in Denver.

G. W. CHEYNEY of Tucson, Ariz, and for several years identified with the Toughnut M. & M Co. at Tombstone, Ariz, died on the 14th inst, after a short illness. Deceased was 49 years of age and his birthplace Philadelphia, Pa. In 1890 he was a candidate for delegate to Congress. During the early '90s he was operating for Eastern people at the Old Glory mine, Oro Bianco district, and at same time was territorial superintendent of public instruction. He leaves a widow and six daughters.

Catalogues Received.

"Pumping by Compressed Air," standard size, 6x9 in, from the Pneumatic Engineering Co., New York City, the subject being treated under the heads of "The Air Lift Pump," "Displacement Pumps, Using Air Expansively," "Displacement Pumps, Using Direct Pressure of Air Without Expansion."

Commercial Paragraphs.

THE Oakland Iron Works has been succeeded by the United Iron Works, which will continue the business. Enoch Winsby is secretary and treasurer, with offices at 330 Market St., San Francisco, Cal.

THE Keystone Driller Co. of Beaver Falls, Pa., have lately shipped two of their placer testing machines to St. Petersburg, Russia. They this week ship two machines, with a number of tools, to Callao, Peru, a machine to Johannesburg, South Africa, and another to Brazil.

New Patents.

DEWEY, STRONG & CO.'s SCIENTIFIC PRESS PATENT AGENCY, 330 Market St., S F., has official reports of the following U. S. patents issued to Pacific coast inventors:

FOR WEEK ENDING AUGUST 18, 1903.

736,345.—RAILWAY SIGNAL—Ammann & Campbell, Spokane, Wash.
736,487.—OIL BURNER—Brunner & Patterson, Haywards, Cal.
736,588.—WATER TRAP—F. B. Charroin, Fairhaven, Wash.
736,695.—PLOW JOINTER—W. R. Criffield, Walla Walla, Wash
736,837.—FLY TRAP—E. F. Davison, Marysville, Wash.
736,513.—PIPE LINE VALVE—C. E. Fowler, Seattle, Wash.
736,847.—STRAP FOR ECCENTRICS—W. Harlog, Blaine. Wash.
736,849.—FRUIT DRIER—G W. Heakle, Vancouver, Wash.
736,850.—TANK—A. Holtgen, S F.
736,411.—LOCATING MINERALS—G I. Leonard, Pasadena, Cal.
736,752.—ELECTRIC RAILWAY—T. Mahoney, S. F
736,857.—BOILER FURNACES—G. Marlow, Sr., Spokane, Wash.
736,766.—PHOTO TRAY—G. T. McKinney, Walla Walla, Wash.
736,416.—STOVE PIPE HOLDER—W. H. Medloa, S F.
736,421.—PUMP—Miles & Storch, Alameda, Cal.
736,534.—SAW SET—J Morin, Seattle, Wash.
736,427.—FOOTSTOOL—Ruth M. Nidever, Myford, Cal.
736,871.—FOLDING CASE—J J. O'Brien, San Jose, Cal.
736,562.—SPOOL HOLDER—Carrie B. Starr, Wilbur, Wash.
736,797.—HAMMER—G J Steele. Canby, Cal.
736,563.—OIL BURNER—A. C. Stewart, Santa Paula, Cal.
736,893.—GARMENT—W. G. Turner, French Camp, Cal.
736,804.—FRUIT LADDER—S S Ward. Napa, Cal.
736,897.—TROLLEY CATCH—White & Duryea, Los Angeles, Cal.
736,557.—FEED MECHANISM—White & Duryea, Los Angeles, Cal.
736,864.—OIL BURNER—T. Williams, S. F.
736,907.—CASING SPEAR—E C. Wilson, Los Angeles, Cal.
736,470.—SAW SET AND GAGE—D. Worden, Whatcom. Wash.
36,495.—DESIGN—BADGE—K. Melrose, S. F.

Notice of Recent Patents.

Among the patents recently obtained through Dewey, Strong & Co.'s SCIENTIFIC PRESS U. S. and Foreign Patent Agency, the following are worthy of special mention:

IGNITING ATTACHMENTS FOR EXPLOSIVE ENGINES —No. 735,997. Aug. 11, 1903. J. D. McFarland, Jr., San Francisco, Cal. One-half assigned to John Bruckman of San Francisco, Cal. This invention relates to improvements in electric igniting devices for gas engines which employ an explosive mixture. One of its objects is to afford a simple, durable igniter of positive action that is particularly applicable for use with engines of the oscillating cylinder type. Another object of the invention is to utilize the oscillatory movement of the cylinder to effect the electrical contact within the cylinder necessary to cause the explosion which gives the impulse to the piston; and a further object is to provide a "breaker" that can be readily detached from the cylinder in case the electrodes become faulty in any respect. While the invention is designed mainly for oscillating engines, it may be readily adapted to engines of other forms.

APPARATUS FOR DISTRIBUTING POWDER UPON VINES, PLANTS, OR THE LIKE—No. 735,887. Aug. 11, 1903. Guiseppe Lagomarsino, San Francisco, Cal. This invention relates to improvements in devices for dusting grape vines, fruit trees, plants and the like with powdered sulphur or other suitable insecticide for the purpose of preserving them from the ravages of insects. Its object is to provide a light, compact, efficient apparatus capable of being easily carried upon the person and having convenient hand operated means for creating an air blast whereby the insecticide may be expelled, and also having means for assisting and for regulating the discharge thereof.

ELECTRIC RAILWAY SYSTEM.—No. 736,752. Aug. 18, 1903. T. Mahoney, San Francisco, Cal. This invention relates to improvements in means for operating electric railways, and pertains particularly to that type of railway in which the main conveying the current to propel the car is connected at intervals with sectional feeders normally out of circuit with the main and adapted to be energized momentarily and successively by the passing car The object of the invention is to improve upon the so called "underground conduit" systems by simplifying construction, affording perfect insulation, and operating the switch mechanism whereby the trolley sections are energized and de-energized magnetically instead of mechanically.

OIL BURNER —No. 736,864. Aug. 18, 1903. T. Williams, San Francisco, Cal. One-half assigned to C R Splivalo, San Francisco, Cal. This invention relates to an apparatus for the preparation and combustion of hydrocarbon oils. It consists in the combination of a shell with oil and steam supply nozzles, an anterior mixing chamber, a second large chamber with a contracted connection between the two, a final chamber and a nozzle discharge thereinto and a second steam inlet passage acting upon and with the products received at this point and previous to their delivery to the burner opening or discharge.

Latest Market Reports.

SAN FRANCISCO, August 28, 1903.

METALS.

SILVER.—Per oz., Troy: London, 26½d (standard ounce, 925 fine); New York, bar silver. 56½c, refined (1000 fine): San Francisco, 56½c; Mexican dollars, 43½c San Francisco, 44½c New York.

A report on the purchases of silver for coinage, up to August 1st, shows that in the new Philippine currency system the purchases have amounted to 9,711,506 96 ounces of huilion. for which $5,145,762 53 has heen paid. The Philippine peso contains three and one-half more grains than our silver dollar, or an amount of hullion worth slightly less than 42 cents. Its currency value on the new 32 to 1 hasis will he 50 cents.

The report of the French experts appointed to confer with the United States Monetary Exchange Commissioners indorses the principle of a gold standard for China and other silver-using countries, hut it points out that the plan is positive only under judicious control of the coinage by the Government and the creation of an adequate gold reserve. It favors a coinage ratio for the Orient, fixing the face value of silver slightly above its huilion value similar to the American system in the Philippines. The French Commission makes reservations upon the proposed purchases of silver, on the ground that it is impossible to foresee the country's need for subsidiary and colonial coinage. Semi-official advices from Russia indicate that the commission appointed by Finance Minister Witte has made a similar conclusion. The French and Russians considered it preferahle to estahlish a uniform system in China hy heginning on a silver hasis and afterward raising it to a fixed gold value, than to hegin on a gold standard immediately.

COPPER.—New York: Standard, $13.75; Lake, 1 to 3 casks, $13.75@13 87½; Electrolytic, 1 to 3 casks, $13.62½@13 75; Casting, 1 to 3 casks, $13.37½; San Francisco: $15 00. Mill copper plates, $17.00; hars, 18@24c. London: £58 17s 6d spot per ton.

LEAD.—New York, $4.25; Salt Lake City, $3.50; St. Louis, $4.00; San Francisco $4.50, carload lots; 4¾c 1000 to 4000 lbs.; pipe 6½, sheet 7, bar 5¾c; pig, $4.75. London: £11 3s 9d per long ton=2.72c per lb.

SPELTER.—New York, $6 00; St. Louis, $5.00; London, £21 2s 6d per ton; San Francisco, ton lots, 6½c; 100-lb lots, 7c.

ANTIMONY.—New York, Cookson's, 7½c; Hallett's, 6¾c; San Francisco, 1000-lb. lots, 8¤; 300 to 500 lbs., 8½¤; 100-lb lots. 10½c.

TIN.—New York, pig, $27.80@28 00; San Francisco, ton lots, 28½c; 500 lbs., 29c; 200 lbs., 29½c; less, 30c; har tin, ℔ lb, 30c @32½c. London, £126 2s 6d spot.

Importations of pig tin into the United States in the past year were larger than in any preceding year. The statistics of the year's imports show that the importations of tin were 88,000,000 pounds, valued at more than $23,000,000. In 1890 the importations were 35,000,000 pounds, valued at about $7,000,000. An export duty of $30 per 133 pounds has been levied on the exportation of tin ore from the British colonies of the Malayan peninsula. The Malayan States produce more than half of the tin which enters into the commerce of the world, their total shipments in 1901 being 50,000 tons, out of a total of 89,000 tons entering the markets of the world in that year.

PLATINUM.—San Francisco, crude, $18.00 ℔ oz.; New York, ingot, $19.00 per Troy oz. Platinum ware, 75@80c per gram.

QUICKSILVER.—New York, $47 00@47.50; large lots; London, £8 12s; San Francisco, local, $44 50 ℔ flask of 76½ lbs.; Denver, $49.50. Export, $43.00.

BABBITT METAL.—San Francisco, No. 1, 10c; No. 2, 7c; No. 3, 6½c; extra, 17½c; genuine, 35c; Eclipse, 37½c.

ALUMINUM.—New York, No. 1, 99% pure ingots, 35c; No. 2, 90%, 30c to 34c.

SOLDER.—Half-and-half, 100-lb. lots, 18.75c; San Francisco, Plumbers', 100-lb. lots, 15 50c.

NICKEL.—New York, 50@60c ℔ lb.; ton lots, 45@48c.

STRUCTURAL MATERIALS.

IRON.—Pittsburg, Bessemer pig, $18.50@18.75; gray forge, $17.10; San Francisco, bar, 3c ℔ lb., 3½c in small quantities.

STEEL.—Bessemer hillets, Pittsburg, $27.00@29.00; open hearth hillets, $28.00@30.00; San Francisco, bar, 7c to 12c per lb.

GENERAL SUPPLIES.

POWDER.—F. o. b. San Francisco: No 1. 70% nitro-glycerine, per lb., in carload lots, 15½c; less than one ton, 17½c. No. 1**, 60%, carload lots, 13½c; less than one ton, 15½c. No. 1** 50%, carload lots, 11½c; less than one ton, 13½c. No. 2, 40%, carload lots, 10c; less than one ton, 12c. No. 2, 35%, carload lots, 9½c; less than one ton, 11½c. No. 2** 30% carload lots, 9c; less than one ton, 11c. Black blasting powder in carload lots, minimum car 728 kegs $1.50 per keg; less car lots, $2 per keg.

CAPS.—3x, $5.50 per 1000; 4x, $6.50; 5x, $8; Lion, $9, in lots not less than 1000.

FUSE.—Triple tape, $3.60 per 1000 feet; double tape, $3.00; single tape, $2.65; Hemp, $2.10; Cement No. 2, $3.00; Cement No. 1, $2.65, in lots of 3000 feet and up.

CANDLES.—Granite 6s, 16 oz., 40s. 10½c ℔ set; 14 oz., 40s., 9½c.

CHEMICALS.—Cyanide of potassium, 98%-99%, jobbing, 24@25c ℔ lb.: carloads, 23@24½c; in tins, 35c; soda ash, $2.00 ℔ 100 lbs.; hyposulphite of soda. 2½@2¾c ℔ lb.; caustic soda, in drums, 3@3¼c ℔ lb; Cal. s. soda, bbls., $1.25@1.50 ℔ 100 lbs.; sks., $1.05; chlorate of potash, 12@13c; nitrate of potash, hbls., 10c; caustic potash. 10c in 40-lb tins; borax concentrated, 7@8c ℔ lb.; roll sulphur, 4@6c; powdered sulphur, 2@3c; flour sulphur, French, 2@3c; alum, $2.00@2.25; California refined, 2@2½c; sulphide of iron, 9c ℔ lb; copper sulphate, 5@7c; chloride of lime, spot, $2 50@2.75; sulphuric acid, in carboys, 66% B, 2¼c ℔ lb.; nitric acid, in carhoys, 8c ℔ lb.

OILS.—Linseed, boiled, hbl., 44c; cs., 49¤; raw, bhl., 42c; cs., 47c; Lucol oil, boiled, hhl., 41c; cs, 46c; raw, bbl., 39c; cs, 44c. Kerosene—Pearl, per gal., 20½c; Astral, 20½c; Star, 20½c; Extra Star, 24½c; Eocene, 23½c; Elaine, 26½c; Water White, in bulk, 14½c; Mineral Seal, iron hhls., 18½c; wooden hbls., 21c; cs, 24c; Mineral Sperm, cs, 26½c; Deodorized Stove Gasoline, bulk, 17c; do., cs., 23½c; 86° Gasoline, bulk, 21c; do., cs., 27½c; 63° Naphtha or Benzine, deodorized, in hulk, per gal., 16c; do., in cs., 22½ c; Lard Oil, E. W. S., hbl., $1.00; cs., $1.05; Neats-foot Oil, pure, hhl., 75c; cs., 80c; Sperm, crude, 70@60c; Natural White, 65c; Bleached do, 50c; Whale Oil, cs, 50@55c.

WHITE LEAD.—Per lb., in kegs: 500 lbs. and over at one purchase, per lb., 6c; less than 500 lbs., per lb., 6½c; in 25-lb. tin pails, ¼c per lb. above keg price; in 1 and 5 lb. tin cans, 100 lbs. per case, ½c per lb. above keg price. Dry Lead—In bhls., 1 ton and over, 6c; do. in kegs, 6½c.

BONE ASH.—Extra No. 1, 5@6c per lb. No. 1, 4@5c.

RED LEAD.—500 lbs. and over at one purchase, per lb., 6c; less than 500 lbs., 6½c.

LITHARGE.—Pure, in 25-lb. hags, 8 @9c per lb.

BORAX.—Concentrated, 7@9c per lb powdered, 9@12c; fused, 25@30c.

BORAX.—Crystal, 7c; calcined, 25c.

MANGANESE.—Pure, ℔ lh., 60c.

SODIUM.—Metal, ℔ lb., $1.00.

MOLYBDENUM.—$2 per lb.

CHROMIUM.—(90% and over) per lb., $1.00.

BISMUTH.—Subnitrate, per lb., $1.60.

MERCURY.—Bichloride, ℔ lb., 90c.

PHOSPHORUS.—(American) ℔ lb., 75c.

SILVER.—Chloride, ℔ oz., 90c@$1.00; nitrate, 55c.

ALUMINUM.—No. 1, 99%, small lots, 37c ℔ lb; 100 lbs., 35c; 1000 lbs, 34c; ton lots and over, 33c, Pittshurg. No. 2, 90%, small lots, 34c; ton lots and over, 31c, Pittsburg.

URANIUM.—Oxide, ℔ lb., $3.50.

ZINC.—Metallic, chemically pure, ℔ lb., 50c; dust, ℔ lb., 10c; sulphate, ℔ lb., .04c.

(These prices are wholesale, f. o. h. San Francisco, unless otherwise noted.)

SITUATIONS WANTED.

A THOROUGHLY COMPETENT ASSAYER and Analyst, 15 years' experience, with a good practical knowledge of mining, milling and smelting, is open for engagement, with chance for advancement. Excellent references. Address "Everett" care of this office.

MINE SUPERINTENDENT WANTS POSITION with a substantial company that has a mill on property. A qualified mining engineer who can run a mine or mill, cyanide plant, assaying and surveying. Address "Mining," this office.

MINING ENGINEER NOW IN CHARGE COPper proposition desires charge of location. Management gold or copper proposition. State terms. Address Box 85, this office.

MINING ENGINEER AND METALLURGIST, at present general manager of a large mining concern in Mexico, desires to change his position. Would need four months' notice. Address F.B.A.S., care of this office.

MINING ENGINEER WISHES POSITION AS superintendent or assistant superintendent at metal mine. Has had eight years' experience in civil and mining engineering, and is surveyor, draughtsman and assayer. Also had practical experience in underground work and handling men. Can furnish transit and two sets halances. Age twenty-eight. References. Address Box 818, Salt Lake City, Utah.

MINING ENGINEER, GRADUATE GERMAN University, at present assistant manager of gold mining corporation and in charge of large amalgamating, concentrating and cyaniding mill, desires change. Thorough experience in treatment of refractory gold ores by all processes. Would like position as manager or assistant manager of producing company. Age 33; unmarried. Best references. Address R. R. 18, care of Mining and Scientific Press

POSITION BY PRACTICAL MINING ENGIneer; 20 years' experience in U. S., Alaska and Mexico. Reference Al. Specialty, commercial mining. Address W., care of this office.

WANTED—A POSITION AS MANAGER OF quartz mine; 20 years' practical experience. Would take charge of a promising, undeveloped property, and could invest some money in it. First-class references. Address "Reno," care of Mining and Scientific Press.

YOUNG GRADUATE WITH SOME EXPERIence in Assaying, Surveying and Draughting, wants position in mine. Salary not so much an object as advancement. Address H.N., this office.

WANTED.

Wanted, 1 First-Class Amalgamator for 20-Stamp Mill.

Wages $4 per day. Board $3.75 per week. Address, giving references,

CHELAN MINING CO., BLEWETT, WASH.

WANTED—A First-Class Assayer and Chemist,

with extended cyanide experience, for position of Assayer and Chemist with large gold mining company, with cyanide plant. Must have best of references. State age, experience and salary wanted. Address "Chemist," care of Mining and Scientific Press.

WANTED TO SELL This Machinery, Cheap.

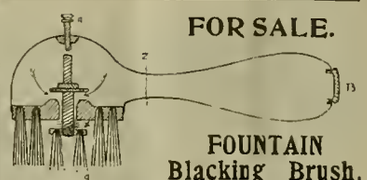
Six-Drill Compressor; Double Cylinder Hoist, good for 800 feet; Large Double Reel Geared Hoist, good for 1500 feet; 60 H. P. Fire-box Boiler. All in good condition. Address "Machinery," this office.

TO TOOL SHARPENERS

and AMATEUR TOOL SHARPENERS! I will send formula, with full instructions, by which you can temper machine or hand steel so that it will stand in any kind of rock and not chip, hatter or break. Result of twenty years' practical experience in Rocky mountains. Price 50 cents. Satisfaction gusranteed or money refunded. C. H. BENNETT, 50 Mill St., Aspen, Colo.

ASSESSMENT NOTICE.

INYO MARBLE COMPANY OF CALIFORNIA.—Location of principal place of business, San Francisco, California: location of works, Inyo, Inyo County, California.



Notice is hereby given, that at a meeting of the Board of Directors, held on the 18th day of August, 1903 an assessment (No. 37) of five (5) cents per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin, to the secretary, at the office of the company, room 20, fifth floor, Mills Building, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the 15th day of October, 1903, will be delinquent, and advertised for sale at public auction; and unless payment is made before, will be sold on WEDNESDAY, the 18th day of November, 1903, to pay the delinquent assessment, together with the costs of advertising and expenses of sale.

By order of the Board of Directors.

CHARLES E. ANDERSON, Secretary.

Office—Room 20, fifth floor, Mills Building, San Francisco, California.

FOR SALE.

FOUNTAIN Blacking Brush.

A New and Cleanly Means of Applying Liquid Blacking.

With no pressure on bristles the small brush is kept in position shown by dotted lines Y, by the spring X. With pressure on bristles, as by rubbing, the small brush is raised to position shown in cut, opening the valve and allowing the blacking to flow onto the bristles as indicated by arrows. Thumb screw A securely locks valve, making brush absolutely tight. Bottle in which liquid blacking is sold can be made to fasten on brush at line Z and serve as a handle.

Pat. in U. S. and abroad. For sale separately or as a whole. For particulars, address E. R. KING, Lafayette, Contra Costa Co., Cal.

Bruce Copper Mines Ltd.

IN LIQUIDATION.

The whole of the property belonging to The Bruce Copper Mines Ltd., with its equipment, for sale by private tender. Including the mineral rights of 20 square miles, modern concentrating mill (400 tons daily capacity), compressor, hoists, etc., in thorough condition.

Parties desiring to put in a tender should have their engineers on the ground without delay; tenders will be closed the 15th September, 1903.

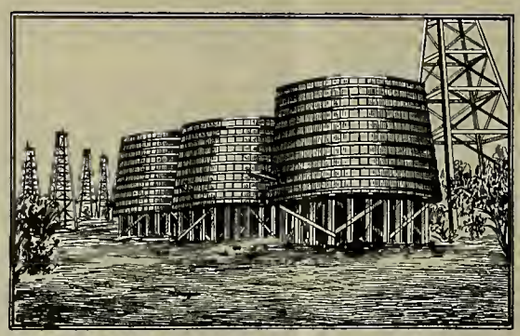
For further particulars, apply to

LOUIS J. ABRAHAMS,
BRUCE MINES, ONT., CANADA.

MINING PROPERTY FOR SALE.
Consists of 13,000 tons of tailings, 25,000 tons of dump—both good values. Water for working same. Situated 3 miles from railroad. No crushing power required. Guarantee a saving of 80%. Partners cannot agree, so it will be sold cheap. Inquire of James McDermott, Brooklyn Hotel, San Francisco.

FOR SALE.
Large quantities of light Steel Rails—16-lb., 24-lb. and 35-lb. sections with fastenings.
MASTEN & MASTEN, 407 Henne Building, Los Angeles, Cal.

EXCEPTIONAL BARGAIN!
ONE FOUR-FOOT FRUE VANNER, fitted with Brownell Patent Lip Flange Belt. Vanner and Belt absolutely new. Address Frlcot & Miller, Latrobe, El Dorado Co., Cal.



Thirty years of lamp making enables us to offer a

MINERS' LAMP
that gives perfect satisfaction. The *Globe Lamp* has a globe and our name stamped on it. We also make *The Star* Miners' and Drivers' Lamps. Write us for circulars and wholesale prices. Sample lamps mailed on receipt of 25c.

NOTICE

of Receiver's Sale of the Electric Plant, Apparatus, and Other Property of the Cochiti Gold Mining Company.

Notice is hereby given that the Receiver, by appointment of the District Court of the Second Judicial District of the Territory of New Mexico, for the County of Bernalillo, in that certain cause pending therein wherein Raymond P. Ripley and others are defendants, will, under and by virtue of an order of said court made August 20, 1903, receive bids for the purchase and sale of all the property of the said Cochiti Gold Mining Company, now in his possession as such receiver. Said property consists of a complete cyanide mill of two hundred and fifty tons capacity, built of structural iron, various other buildings such as stores, boarding house, store house, bunk houses, etc., etc. The machinery consists of dry crushing apparatus, Davis and Allis finishing rolls, twenty steel leaching tanks of two hundred and one hundred and thirty tons capacity; also sixteen thousand dollars worth of mining and mill supplies; office furniture, etc. And also, situated at Madrid, N. M., an electric power plant and structural steel building, one eight hundred horse power engine, one 600 K. W. generator, complete switches etc., etc., for a twenty-thousand-volt transmission, and other property such as is generally used in connection with such a mill run by electricity, including one hundred miles of copper transmission wire.

Also the Alhemarle, Pamlico, Huron, Ontario patented mining properties, and the U. M. C. and three-fourths interest in the Red Cloud, containing in all almost one hundred acres and having five thousand feet on the strike of the vein. These mines and the mills are situated at Alhemarle, Sandoval County, New Mexico, twenty-four miles from Thornton on the A. T. & S. F. Ry.—the other property at Madrid on said railway.

Bids will be received by the undersigned for the sale of said property, or any part thereof, for sixty days from the date of this notice. For the Madrid power plant property, and the electrical machinery, bids must be itemized, fixing the price to be paid upon each separate article; and, also, separate bids must be submitted for the wire, on account of conflicting interests in the property. The buildings and other property may be removed by purchasers from the premises on which they are located.

A reasonable deposit, certified check or cash, must accompany each bid as a guaranty of good faith and responsibility.

Lists of the property and all other information requested will be furnished upon application to the Receiver.

WILLIAM SPENCER,
Receiver.

P. O Address: Albuquerque, New Mexico.
August 21, 1903

The Mines of Park City, Utah,
Have furnished 70% of the lead, 62% of the silver, 70% of the dividends of the State. Send 20 cents for 24-page illustrated edition of Park City Miner, with map. N. B. DRESSER, Park City, Utah.

It's THE BEST
(and WE make them.)

The above picture shows one of our Traction Engine outfits in use in Guatemala, C. A.; was used during late war by that Government for transportation of troops and supplies. Engine, 110 H. P.; car capacity, 16 tons each. Can be used on from 5 to 30 per cent grades, depending upon condition of roads. Over 150 in use on this coast alone, and every one a money maker. Let us know the kind of freight you are hauling, per cent of the grades, usual conditions of roads, and we will tell you how to save ½ to ⅓ of your present cost of hauling. You know we also make the best 2 to 75 H. P. Crude Oil Engine, with Improved Generator and Self-Starter, in the market.

Write for our new Catalogue No. 18, and we'll do the rest.

TO indicate the advance in machinery in the last decade, it is worthy of note that at the St. Louis, Mo., Exposition next year there is promised to be exhibited a 3000 H. P. gas engine.

THE inevitable swing of the pendulum has started silver on the up-grade again, and the scepter of supremacy in its purchase is shifting from London to New York and San Francisco. It is expected that the international conference will adopt a ratio of 32 to 1, which would tend to bring the price up to 65 cents per ounce, with the usual quickening effect on its production, which of late years has materially declined, it having become more and more a by-product.

AN ingenious California mine superintendent is considering a scheme to build a water-tight bulkhead in an abandoned crosscut in his mine, and to utilize the chamber so created as an air receiver, connected with the compressor main line. There is some diversity of opinion as to the result. The plan may possibly be a success if the chamber is first allowed to fill with water in order that all the cracks may be silted up and thus become impervious to either air or water. Bulkheads are made essentially water-tight, then why not air-tight?

EIGHT years ago Oren Root, aged 22, was driving spikes on a New York street railway at $1 75 per day. To-day, the same Oren Root, aged 30, is general manager of the system with direct supervision of 14,000 men. That is a good example of the possibilities in every branch of mechanical industry and a good answer to the pessimist who says: "A poor man has no chance any more." Never in the world's history were there better chances than right now for a man who has it in him to go ahead. However "poor" he may be if he be rich in manhood he is bound to get ahead; and however rich he may be if he is poor in the qualities that make for material success he is certain to fall back. "Pull" or influence may get a man a fine position, but he must have merit to hold it. When Root was driving spikes for $1.75 a day he drove them well, and whenever he had a chance he showed the stuff that was in him. He didn't watch the clock, and wasn't afraid he was doing too much. Men of affairs are always on the lookout for such assistants and the world is theirs to have and to hold.

THE editorial in last week's issue on a cabinet department of mines and mining as being a national necessity has elicited a more than ordinary number of responses, mostly affirmative. A mining engineer furnishes an instance illustrative of just why, through the years, the plea has been made by this paper for a department of mines and mining: some modification of the requirements occasioned from either the whim or notion of a temporary clerk attached to the Interior Department of the United States Government: That portion of the United States statutes governing mining locations requires that the United States mineral monument shall be established where the mineral survey is more than 2 miles from a corner of the public survey and corner of each mineral location connected thereto. If within 2 miles, the connections are made with the public survey, but the California Surveyor-general now rules that each and every mining monument established must be connected with a corner of the public survey, regardless of distance. Every mining surveyor will realize what a hardship this ruling, if strictly enforced, will be to a locator should the essential point happen to be from 7 to 20 miles distant. This latest ruling of the California official is made mandatory on him, because of a letter received by him with instructions to that effect from Washington, though Surveyor-Generals in other States say they do not require such connection because they have had no such letter. In the absence of further present knowledge on the subject, it may be assumed in this case, as in others previously brought to our attention, that this latest "ruling" is based purely on the whim or notion of some $100 clerk at the national capital who never saw a mining location, and who wouldn't know it if he did see it, for, unfortunately—and to the shame of our government, it must be confessed—that all those matters pertaining to the nation's foremost industry have been relegated through the years to some desk in a corner of an overworked department, and whoever happens to be in charge of the desk at that time can usually rule or decide just as his whim suggests, regardless of the equities of the case and to the injury of the mining industry, the vexation of those who know better, and the expense and annoyance entailed on many who can often poorly afford to pay the extra money made necessary by the whimsical rulings of a Washington clerk.

THE Congress which meets next Monday at Deadwood, South Dakota, is the sixth gathering of that body. It was called together in Denver, Colo., in 1897, as the Gold Mining Convention. Its second annual session was in Salt Lake City, Utah, in July, 1898, when it was styled the International Mining Congress. At Milwaukee, Wis., June 19, 1899, was opened the third convention. The fourth was held in Butte, Mont., in 1901; the fifth at Boise, Idaho, in 1902, and the name was then changed to the American Mining Congress. It is the only organization of the kind, and as such has received much prominent mention from mining journals throughout the nation, the general estimate of the gathering being commensurate with its merits. If it has done little good, it certainly has done no harm, and is illustrative of what a virile organization of the kind could do, strongly officered and rightly run. It deserves encouragement for its possibilities, rather than criticism of its weakness, for it is susceptible of something better than being made a mere excuse for "special" numbers of sundry mining periodicals with a view to increased advertising. The American Mining Congress can be just what American mining men choose to make it, and a pushing dignified organization, with some semblance of authoritative utterance, would be of substantial benefit to the mining industry.

DURING the next ninety days considerable annual assessment work will be done on thousands of unpatented mining claims west of the 100th meridian. In connection therewith, it is worthy of note that, unless the locator considers the claim worth working or patenting, it is of no use or need to spend any money on it. Of course, $100 worth of work or improvement must annually be put upon an unpatented mining claim in the United States if one wants to hold it; but if it isn't worth holding, there is little use of annual assessment work. Unless one thinks his claim of some value, it were useless to spend money "just to keep up the title," for he might keep on putting $100 per year for ten years on the claim in that way; and if he missed one year, he would have no better title than if he had put no work on it at all. In such a case, viz., where the locator has little or no belief in the value of his location, he need spend no money on it, but go on the proposition that others are of the same belief concerning it; and if they are, then he can let it lapse, and if any one else has no better opinion of it than himself and does not jump it, he can relocate it later on and save his money. A good many, however, have a better opinion of their claim than this, yet take the chances on relocation or trouble of some kind by neglect to do the necessary annual work. This is a grievous mistake. If the claim is worth consideration at all, it should be taken care of by sufficient annual work and improvement to prevent any possible trouble as to title. Meanwhile a United States patent should be secured at the earliest date. If a man wants to keep on owning the claim, it is vastly more comfortable to have a clear title to it; and if he wants to sell it, next to the value of the property, nothing will expedite the transfer so satisfactorily as to be able to show an original deed from Uncle Sam.

RECOGNIZING that cheapness is not regulated by what one pays, but by what he gets for what he pays, and that the value of an advertisement is determined by its results, the leaders in many branches of business connected with mining or metallurgy advertise in these columns. And in this regard it is to be said that our readers can be supplied by them with what they need at fair prices. It is still further to be said that those advertisers deserve the business they seek, for it is their trade announcements that enable the publisher to furnish this journal at such small cost to subscribers. It is manifest to every one that such a publication as the MINING AND SCIENTIFIC PRESS could not be placed in the hands of its readers at a cost to them of less than 6 cents per issue were it not for the advertising patronage, and it is equally manifest that in buying from those who so advertise herein the reader really benefits himself in more ways than one, for beside the consciousness that he is dealing with reputable firms, it is to be borne in mind that it is those firms who make it possible for him to get such a journal for $3 per year; for, as stated, without the income received from advertising, this journal could not be issued for any such amount and continue to maintain its high standard of technical excellence. This fact holds true of nearly every publication of large circulation, statistics from the business office showing that the cost of producing a journal exceeds the income from its subscriptions, with the effect that it is the advertisers who make possible its manifest value and continuous existence. Of course the advertiser doesn't place his advertisement in this paper for philanthropic reasons or just because he wants to have the reader regularly supplied with even so good a publication; he advertises for the profit its wide circulation brings him, for in no way could he get so great a hearing at so small a cost, he being assured profitable publicity, but it is manifest from the above that it is of mutual interest to buy from firms that advertise. If what they have wasn't good they wouldn't or couldn't advertise it in the MINING AND SCIENTIFIC PRESS.

CONCENTRATES.

A 16-CANDLE POWER incandescent electric light would take half an ampere current at 110 volts.

THERE is nothing impossible geologically in marine shales carrying gold in commercial quantities.

"CAPACITY," as applied to a gold dredge, is the actual amount the dredge can lift running full buckets, with the ladder lying at an angle of 45°.

A 3% SOLUTION of hydrogen peroxide injected beneath the skin with a hypodermic syringe furnishes an antidote for cyaniding poisoning by inhalation.

APPROXIMATELY, a pipe 3 feet long will hold as many pounds of water as the square of its diameter in inches. A 5-inch pipe will hold about 25 pounds of water in each yard of length.

TO ESTIMATE the horse power obtainable from 1 miner's inch of water, multiply the head of water in feet by the decimal 0 0024147: the product is the theoretical horse power so procurable.

QUARTZ is a crystallized mineral as originally deposited; quartzite is a rock of quartz, granular and secondary. Quartz occurs in veins; quartzite in strata. Quartzite is sometimes a metamorphosed sandstone.

REGARDING last week's illustrated description of an "inverted siphon," such a construction as that suggested, "a mile long, of wrought iron, and 18 inches diameter," could be made to work all right. With a 400-foot head, the approximate pressure would be 400 pounds per square inch.

THERE are many recipes and formulæ for welding steel and iron. The following is recommended: Carbonate of ammonia, one-half pound; borax, two pounds; muriate of ammonia, one-half pound; black oxide of manganese, one-quarter pound. Beat up in a mortar and mix well.

WHILE interesting as a laboratory experiment, liquid air has not nor is it likely to be put to successful commercial use in or around a mine. A 2 H. P. engine working continuously for one hour would produce only enough liquid air when converted into power to run a 2 H. P. engine one minute.

THE Slocan district, B. C., is the only British Columbia province, so far as "Concentrates" knows, that has shipped zinc ores to the United States for treatment. That section has sold zinc concentrates to the Lauzon Zinc Co., Iola, Kansas, the railways making a special rate of $11 per ton freight.

ITALY AND CANADA produce the best asbestos, the Italian quality being the superior, having longer, silky fiber. Italian asbestos contains 80% silicate of magnesium, and 30% oxide of iron. The South African asbestos carries 50% silica and about 40% oxide of iron, being too brittle and stony for use.

EASILY FUSIBLE ALLOYS must contain cadmium. Such an alloy is four of lead, seven to eight of bismuth, and one to two of cadmium, and which fuses between 66° and 72° C. Lipowitz's metal, which softens at 55° C. and becomes perfectly liquid at 66°, consists of four parts of tin, eight parts of lead, fifteen of bismuth and three of cadmium.

THERE are several formulæ for compounds to keep machinery from rusting. Take 1 ounce camphor, dissolve it in 1 pound melted lard; remove the scum, then mix with the camphor and lard as much fine black lead as will give it an iron color; clean the machinery well; smear with the mixture. After twenty-four hours rub off, then clean with soft cloth.

IN woodworking shops an exhaust system is often used by which all shavings and sawdust falling from the machines are carried away. A system of main piping is fed by the exhaust pipe attached to each machine, and furnished with a large fan, which draws all the waste products into the pipe and conveys the contents into a chute, which, in its turn, automatically carries them along to the boiler house, where they are consumed.

BESIDE the pneumatic portable hammer—an admirable device driven by compressed air—an electrical hammer is also becoming of general use in chipping, riveting and similar work, operated by a motor of ¾ H. P., cheaply installed and of economic value. The electrical hammer has the advantage of long-distance power transmission, and, like its pneumatic brother, has a range of service and a record for economy and effectiveness that makes its use worthy of consideration.

NEXT to skilled judgment, the best safeguard while following or intersecting veins is the judicious use of crosscut work. Whenever doubt exists this should be extended far enough to include other crevices and give decisive information. Generally speaking, one crosscut in the line of an ore shoot is worth a dozen elsewhere. Well-designed mine maps, with plenty of sections and kept up with the work, are always necessary for good work underground. This is particularly the case in irregular or complicated ore deposits. Nevertheless it is not uncommon to find large mines operating without maps or with a mere apology for one.

WHEN cement is dissolved in dilute hydrochloric acid, part of the calcium silicate is not decomposed, but merely dissolves, and is precipitated on neutralizing the acid with ammonia. To analyze the cement, dissolve one gram in dilute hydrochloric acid, add ammonia and filter off the precipitate of iron, alumina and silica. Redissolve this precipitate in concentrated hydrochloric acid and reprecipitate with ammonia. The two filtrates and washings are then collected for estimation of calcium therein. It is advisable to dissolve the ignited calcium after weighing in hydrochloric acid and estimate the SiO_2, Al_2O_3 and Fe_2O_3 it may contain.

ANTIMONIAL LEAD is a by-product of base silver-lead bullion refining. In Colorado such base bullion will contain between 3% and 4% antimony. Antimonial lead will run from 10% to 50% antimony. That carrying from 20% to 30% is considered best adapted to commercial use. There is an electrolytic process of extraction of antimony from ore in which the antimony sulphide of the ore is dissolved with sodium sulphide. This solution is electrolyzed in a vat divided by a diaphragm, the antimony solution being put in the cathode compartment filled with caustic soda solution to which has been added enough ammonium chloride to raise the specific gravity to that of the antimony solution.

THE only reason few hydraulic gold working patents are weekly recorded and so many smelting and process patents are is because that is the way they are furnished by the U. S. patent office, and the weekly illustrated page of new patents in each issue is an abstract of the official reports. "Concentrates" would be pleased to publish any gold hydraulic mining patent when so reported from the patent office. This does not mean that hydraulic mining is at a standstill, but many of the devices long ago invented are so admirably adapted to the work for which they were designed that they continue to be used from possible inability to improve on them. Meanwhile, if the questioner will note the weekly page of published patents he will observe dredger devices and other improvements which constitute the latest phase in large hydraulic mining propositions.

THE limit of electric heating is purely financial. To convert heat into other energy with a very small efficiency and to send it out by expensive cables, and then to degrade the energy down to heat again, is obviously much dearer than burning coal or gas direct. The electric arc and incandescent lamps are essentially cases of electric heating. By far the most important use of electric heating is the furnace. Here the temperature available is only limited by the volatilization of the electrodes, and this enables one to get temperatures otherwise unavailable, so that one can get chemical actions which are impossible at lower temperatures, either because they are endothermic or because the materials do not come into chemical contact at ordinary temperatures. It is impossible to say what the limits are in the electric furnace. Probably the temperature is limited by the volatilizing of carbon. The products are not limited to endothermic compounds. The furnace is useful for the reduction of metals and phosphorus and for melting glass and silica for optical and laboratory purposes, and perhaps for cooking utensils and evaporating pans and crucibles in chemical engineering and metallurgy.

THERE are great quantities of gold-bearing black sands scattered all over this west half of America, on the ocean beach and on the banks of big rivers, and considerable successful effort has been made at saving the gold, but as a general thing it has never been at any place a very big proposition, and rarely it doesn't more than pay wages. All sorts of schemes have been tried. The biggest trouble in working the sand by the sluicing process is that the gold is so extremely thin and light that the water carries it off even easier than it does the grains of sand, which have more body to them, and it is the sand, and not the gold, that settles down in between the riffles and packs there, hard. Should the head of water be increased or more slant be given the sluice box, it only makes the gold go through all the more. The cyanide process goes far toward solving the problem, the principal trouble in that case being the fact that without proper concentration the small amount of gold and the large amount of iron interferes seriously with the necessary chemical action of the zinc shavings on the cyanide solution, ofttimes preventing precipitation, largely by reason of the iron, which in the cyanide solution will prevent the zinc from going into the solution to replace the gold.

AT most Arizona copper works remelting furnaces have been dispensed with. At the Copper Queen the matte, made from a mixture of oxidized and sulphuretted ores in cupolas 120 inches by 42 inches at the tuyeres, is discharged into large wells which are mounted on rollers, and rotated like the converters by hydraulic machinery, one well standing in front of each furnace. From the wells the slag flows continuously, and the matte is poured directly into the converter, which is placed on a lower level. There is thus secured the minimum of handling. The capacity of each furnace is adjusted accurately to the capacity of its own converter, but the furnace has occasionally to wait for a converter and the converter for the furnace, as the matte should not be poured until the well is nearly full, lest the slag in any quantity accompany it to the converter. The tilting well was adopted after experiencing the difficulty of controlling the flow through a tap hole directly into the converter from a deep receptacle holding so many tons of matte. Each furnace is provided with two wells in tandem. An electric crane is used to move the matte from any furnace well to any converter, and to lift the converter slags and pour them into one of the wells nearest a furnace stack. At Nacosari, Sonora, Mexico, the well is placed to the side of the furnace instead of in front, and can be tilted to the rear as well as to the front, and so when it has to be emptied of matte the supernatant slag can be poured off to the rear.

IN the adjustment of water to a belt concentrator, it should be noticed that the proper quantity of water is something to be carefully regulated. There should be on each side of the belt a small streak of sand—that is, there should be less water there than in the balance of the pulp elsewhere on the belt. If the water feed be not regulated in this manner, the sides will be sloppy and a loss will result. When this condition is observed, too much water is being added. When too little water is fed, there will appear broad bands of sand at the sides of the belt and sand will pass over with the sulphides. Clean sulphurets are always desirable, and, if they can not be obtained on a single machine without too serious a loss, the pulp must be classified by passing through a pointed box and the coarse fed to one machine and the fine to another. In some mills all the concentrates are "run dirty"—that is, allowed to carry some sand, in order to secure all the sulphides in the concentrate. This concentrated material is then reconcentrated on a separate machine. The usual result is two products—a clean, high-grade sulphide and a low-grade "middlings," containing more or less sulphide of lower specific gravity than the high-grade material, and of lower value. This plan has been found to give satisfaction in the treatment of quartz containing much soft, slaty rock, in which there is a good percentage of sulphurets. Usually these sulphides are found to be low grade.

THE cost of timbering a shaft depends on the method of timbering employed, the size of the shaft, size of timbers, kind of timber used, cost of labor, and to a great extent on the ability of the workmen to do the work as speedily as possible while doing it properly. There is a small difference in first cost of timber between the overlap framing and the dovetail framing, but this is not material. As to the advantage which either method may possess over the other, it is not clear that there is any such advantage under ordinary conditions, though it is undoubtedly better to employ the overlap in a shaft where the ground shifts or shows a tendency to do so. The item of timbers broken or displaced by blasting in some shafts is an item of considerable amount, particularly where the timbers have to be carried close to the bottom of the shaft, owing to the dangerous nature of the ground. Some shafts are timbered with logs carefully hewn, but this is usually done where it is impossible to obtain sawed timbers. A double compartment shaft on the Mount Pleasant mine, near Grizzly Flat, El Dorado Co., Cal., is timbered to a depth of nearly 300 feet with timbers 12x14 inches, which have been hewn with such great care that one is likely to mistake them for sawed timber, without a careful inspection. The work done in hewing and graining such timbers would probably bring the cost to a figure far above the price a sawmill would charge; but in the absence of the sawmill, the miners had recourse to the ax and adz.

AT many shafts it is found economy to make prompt changes from ore to water bucket or from ore skip to water skip. Where large quantities of water are to be handled by bailing, and particularly where the ore-hoisting compartment is of necessity used for this purpose, it is advisable to provide large valve skips or buckets for this purpose, and it is always economy to have some convenient arrangement to quickly make the change. At the collars of vertical shafts this may be speedily accomplished by building a semi circular track at a proper height above the shaft and near it, on which a traveling block may move, and to which the several skips or buckets for ore or water, together with any extras, may be suspended. When a change of skips or buckets is necessary, that in use in the shaft, the movable guides are swung out of place, the skip hoisted to proper position and made fast to the traveler and the cable detached. The skip may then be run on the crescent-shaped track to the right or left, and another substituted for it, the guides replaced and in a few minutes the hoisting may be resumed. At inclines two methods are employed. Either a gate is opened in the main track and the skip is run on a horizontal track in the rear of the shaft, or a false track is thrown across the shaft from the hanging wall side, and the skip or bucket which had first been hoisted up into the head frame is allowed to descend, crossing the shaft on the false track and running out onto a horizontal track and another substituted for it. This is done by switches so arranged as to make the skips readily interchangeable. Economy in labor and time should be studied at every mine in order to reduce working costs to a minimum.

New Century Drop Motion Jig.

The jig as a machine for concentrating ores has maintained its position in well designed ore dressing plants where coarse concentration is possible, in spite of attempts to replace it with various other types of machines, none of which have wholly equaled it in capacity, quality of product, percentage of saving, or attention required to operate it. This statement, of course, refers to those classes of ore which are susceptible to the jigging process.

As a component part of a modern concentrator, it in no way conflicts with the legitimate field occupied by many of the excellent tables and vanners now in use. But while the machinery used in nearly every other department of concentrator work has during the past twenty years been undergoing constant evolution, always toward improvement (as will be readily called to mind by noting what vast strides have been made in the crushing department, in accurate sizing of materials, and especially in the treatment of fines), the jig until recently has remained practically what it was twenty years ago. Attempts have been made to improve the jig and overcome objections to the eccentric motion plunger actuating mechanism by substituting a device which would give it the required differential motion.

The New Century differential motion jig is one of the latest developments of the jigging machine, and is not in any way a radical departure from the ordinary jig, but is designed as an improvement of that machine, in that the plunger mechanism is so constructed as to more nearly realize present requirements, and in its method of removing middlings from the ore bed for regrinding by means of its New Century ore bed draw. This jig is now being introduced in several large concentrating plants. In some recent tests reported made on a three-compartment jig on the silver-lead ores at Park City, Utah, and on the copper-iron sulphide ores at Butte, Mont., it is stated that as compared with another make of jigs it showed greater capacity, used about one-half the water, and required less than one-half the amount of power, and making a higher grade concentrate.

The standard New Century jig has compartments 24 inches wide and 36 inches long, both the plunger and ore bed compartments being of the same size. The tanks are made of Oregon fir, 3½ inches thick, all corners and intersecting joints dovetailed and rodded down from the top through the sills at the bottom.

In place of the ordinary eccentric on the shaft, there is keyed a steel spiral cam, having an amount of drop somewhat in proportion to the length of stroke under which the jig is to operate. Extending down over the shaft and cam at each plunger compartment is an A-shaped casting, the two lower lags of which are bolted to the plunger proper, to become what is known on the Hartz jig as the plunger rod. Above the cam in this casting, with babbitted axles, is a 3-inch steel roller, the surface of which may come in contact with the revolving cam. From the top of the A-shaped casting extends a heavy stud bolt up through a 5-inch wrought steel I beam, which is supported by the iron brackets, the bases of which form the bearing boxes for the jig shaft. Around this short stud bolt, and abutting against the under side of the I beam, is a coiled steel spring with a nut on the stud at the lower end of the spring, designed to give the spring any desired compression. Above the I beam, and on the same stud bolt, is another nut, which can be adjusted up and down on the thread of the bolt.

As the shaft revolves and the cam comes in contact with the roller, it raises the entire plunger, with its mechanism attached, and compresses the spring against the under side of the I beam. When the highest point of the cam is reached by the roller the spring, acting with gravity, forces the entire plunger mechanism rapidly downward until the nut on the upper end of the stud bolt reaches a buffer on the top of the I beam, when the movement of the plunger is instantly stopped.

The aim of the builders is that by regulating the nut on top of the I beam any desired amount of stroke can be obtained, and that by regulating the nut underneath the spring any desired force of stroke can be obtained, and that both of these adjustments may be made while the machine is in operation.

The construction of the plunger used in the jig is novel, and performs an important part in the working of the jig. Instead of fitting the compartment closely, the sides of the plunger are cut free and slope away from the walls of the jig. On the sloping sides of the plunger is secured a flap valve material, the lower edge of which extends flush with the compartment walls; around the compartment at this point is placed a strip of enameled sheet steel, against which these valves operate.

During the instant of quick descension of the plunger these flap valves are forced outward to thoroughly pack the space on all four sides of the plunger, and to force all the water represented by the stroke displacement of the plunger up through the ore bed; and during the comparatively slow upward motion of the plunger, as the roller moves up the incline plane of the cam, the valves are to relax and permit an easy flow of water to the under side, this being designed to prevent any tendency to produce undesirable suction effect.

It is argued by the manufacturers that by reason

of the peculiar quality of the stroke obtained by the mechanism above described—that is, a comparatively slow up motion and a comparatively quick down stroke, with a short period of rest between each—the required conditions are realized for producing the maximum stratifying effect on the materials forming the mixture of ore and gangue in the ore bed, on the ground that the effect on this motion is to raise it in suspension during the down stroke of the plunger, and permit it to settle and arrange itself under the laws of gravity only, without the intervention of any outside disturbing forces, such as suction, etc.

It might appear that so short a stroke would not sufficiently actuate the bed and give it the necessary lightness to enable the various materials to seek their proper level, but the makers assert that with ½-inch stroke a three-compartment New Century jig will satisfactorily handle forty tons per day of material through a four and over a six-mesh screen, and do it with less than twenty gallons of water per minute furnished to the three plungers combined.

On any jig when in operation middlings, especially if they be of the lighter kind, with gravity approaching that of the gangues with which they are associated, will not readily find a side draw through which they can be discharged for regrinding, but tend to go out along with the tailings and compel the mine owner to regrind the whole tailings product or suffer a loss in values. It is argued that the only successful device for removing middlings must be one which draws them at every point at the tail end of the jig alike, as much from the back corner as from the front or in the middle. The New Century ore bed draw is designed to do this. An inside independent cast iron hutch is placed in the ore bed compartment of the jig at the tail end of the last compartment. Between the sides of this casting and at the top where the tailings overflow from the jig is a rotating valve made of a piece of shafting, usually 1 1/16 inch in diameter.

Transverse to the axis of this valve, and extending to its center, are cut a series of grooves, usually about ¾ inch wide. The number of grooves depends somewhat on the amount of material to be withdrawn as middlings, but usually not more than five are necessary.

Over the casting and the valve is placed a shield, over which the tailings flow out of the jig, with a lip extending downward and coming within close proximity to the ore bed sieve. Underneath this lip the middlings when settled on the ore bed can pass without going out of their due course, and the motion of the plunger throws them over through the grooves in the valve above mentioned, into the cast iron hutch, from which they pass out of the jig through an opening provided.

This ore bed draw can be placed on any other compartment for removing coarse concentrates when the amount of concentrates being so removed is more than can be successfully handled by an ordinary side draw.

This jig is manufactured by the American Concentrator Co. of Joplin, Mo., where probably more machines of the jigging type are used than in any other part of the United States, there being over 500 completely equipped jigging plants within 20 miles of that city. Several scenes surrounding Joplin are presented herewith, illustrating the character of the country and of the mining plants of which jigs form so important a part.

Some Structural Features of the California Gold Belt.

NUMBER III.

Written for the MINING AND SCIENTIFIC PRESS by W. H. STORMS.

The impression that the mother lode is a simple fissure is erroneous, excepting in as far as has already been indicated; but at Sutter Creek and vicinity just the reverse is the case. From the Argonaut on the south to the Keystone on the north, a distance of about 4 miles, a study of the lode is both interesting and important, in view of the large production made by that section. The mines within these limits have produced upwards of $50,000,000 in gold.

In and about Sutter Creek the surface exposures everywhere indicate great disturbance of the slates and schists. Folds and faults are numerous, and the underground workings have also developed a similar condition.

The east branch from the split in the Mahoney passes northward through the Mahoney and Belmont, as previously explained, and it is probable that the veins opened in the workings of the Mutual mine, half a mile to the northward, are on a portion of this system. The ore in the Mutual mine is of a different character from that usually found on the lode, containing a large proportion of arsenical sulphide and comparatively little pyrite. What becomes of the Mutual fissure northward has never been determined. It is not recognized in any of the workings of mines in that direction.

The west branch of the Mahoney strikes directly into the Lincoln mine. This is a mine worked at large profit in the early days of mining on the lode and is said to have produced about $1,500,000 to a depth of 350 feet. The vein was of good size—10 feet more or less—and is said to have carried $40 per ton. After years of idleness, the property was reopened and a shaft sunk to a depth of 2000 feet, but without finding a body of payable ore below the 350-foot level. An investigation disclosed the fact that the vein extending from the surface to a depth of 350 feet was faulted at that level. The fault strikes approximately with the vein and dips at a slightly greater angle than the vein. On the hanging wall, or eastern side of the fault plane, the formation dips normally to the eastward, conforming essentially to the general dip of the country, throughout the lode. All the country to the west of the fault dips westward, in proximity to the fault plane, but gradually assumes a position nearer the vertical at some distance from it. A more perfect example of a normal fault could not be imagined.

The accompanying sketch (Fig. 2) illustrates the condition as observed by the writer in the Lincoln

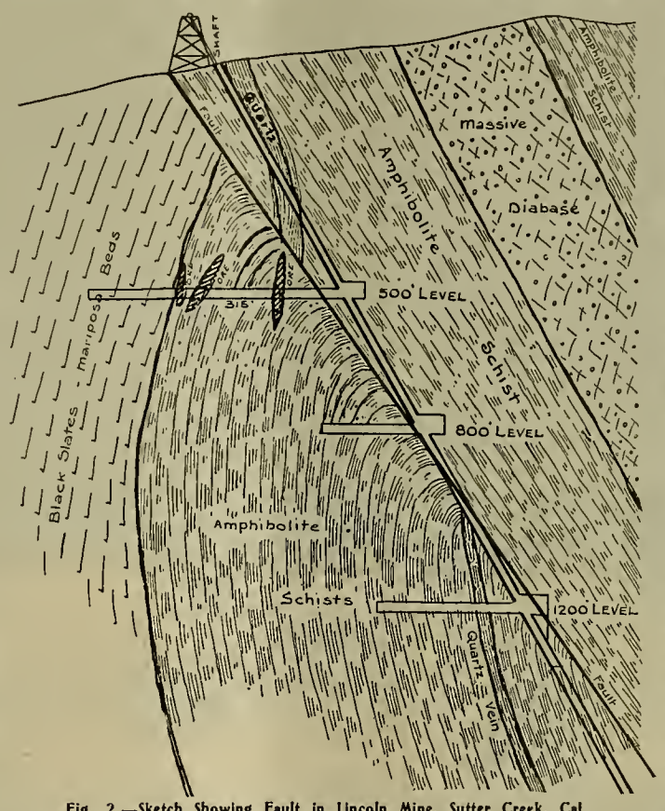

Fig. 2.—Sketch Showing Fault in Lincoln Mine, Sutter Creek, Cal.

mine in 1900, when the deepest workings were 1200 feet from the surface. Since then the shaft has been continued to 2000 feet and a large amount of exploratory work done, with no material change, and confirming generally the condition as indicated in the sketch. Several veins and small shoots of ore were encountered, as shown, but none of them proved of payable value. This fault evidently represents a large displacement, but how much no one can say. The natural inference would be that the vein should be found to the westward; but as far as development now occupied by the several veins, was not sufficiently strong to disrupt the tough, massive diabase and died out, as it were. The county road from Sutter Creek to Amador City passes across the formation and goes well to the east of any known veins, and then swings back to the westward, recrossing the upturned strata, and at the contact of greenstone schist and slate, where the experience to the southward would suggest looking for it, there is no vein nor fissure of any description. This contact has been explored, however, and several pockets discovered in the North Star, Wabash and Talisman mines.

The Keystone fissure system consists of several veins, in black slate, and one large, massive vein of gray ore, the latter nearly 150 feet in width on the 800 level. This system of fissures has proven very valuable and has been extensively worked to a depth of 1575 feet, though the greater amount of development has been above the 1000-foot level.

These fissures pass southward and are found in the South Spring Hill mine and in the South Keystone, or MacIntyre mines. They strike southerly, toward the town of Sutter Creek, and a gulch indicates their general course in the usual manner. If the course of these fissures, as indicated in the South Keystone property, is continued southward, the fissures will pass several hundred feet west of the Lincoln workings. The general system of veins of the Sutter Creek and Amador City groups of mines is indicated in the accompanying rough sketch. (Fig. 3.) North is to the left. The diabase mass near the center is apparently the disturbing element in the continuity of these two systems. The heavy black lines indicate the veins, the split to the right of the diabase area being in the Mahoney mine. The Lincoln lies between the diabase and the forks of the vein. The parallel system of veins to the left is in the Keystone, South Spring Hill and South Keystone mines. Southward from the South Keystone these veins are not developed; but all indications which may be observed on the surface and in shallow development indicate that the above is approximately the correct solution of the structural geology of this district and the disposition of the veins. Northward from the Keystone the vein system continues, but has not been so extensively developed as to the southward; but conditions are somewhat similar to those in the Keystone proper. The Bunker Hill mine, about 5000 feet north of the Keystone, is developed to a depth of 1400 feet and has handed and massive veins, occurring under conditions similar to those previously described.

(TO BE CONTINUED.)

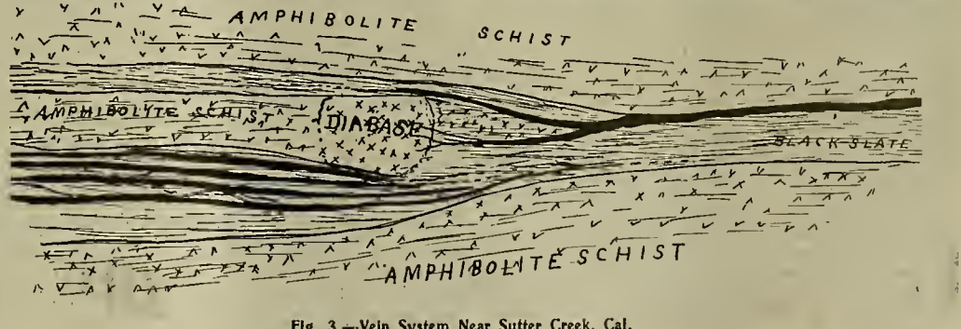

Fig. 3.—Vein System Near Sutter Creek, Cal.

GEOLOGIC FIGURES from the United States Survey show that the total production in the United States of crude petroleum in 1902 was 80,894,590 barrels; progressed, a vein similar to that mined above the 350-foot level was not discovered.

The next mine of prominence north of the Lincoln is the South Spring Hill, and beyond that the Keystone, the latter with a record only second to that of the Eureka, in Amador county. The vein system of the Wildman-Mahoney and Lincoln mines does not extend northward beyond the Lincoln, the west branch running up into a hill of diabase, between the Lincoln and Mutual, and scattering evidently terminates.

All of the mines previously described north of Jackson lie at or near the contact of amphibolite schist and black clay slate; but these conditions change at the north end of the Lincoln. It looks as though the stress which caused the formation of the fissures,

69,389,194 barrels in 1901—an increase of 11,505,396 barrels, or 16.5% over that of 1901 and of 27% over that of 1900. The greatest portion of the increase in 1902 came from Texas and California, the gain being 5,830,994 barrels, or 132.7%, for Texas and 5,187,518 barrels, or 59%, for California, as compared with their respective productions in 1901. The value of the crude petroleum produced in 1902 was $69,610,384, or 86 cents per barrel, that for 1901 having been $66,417,335, or 95.7 cents per barrel—a decrease of 9.7 cents per barrel, or 10% in 1902. The gross amount received for the total product in 1902 was only $3,193,013 greater than that in 1901, although the increase in output was about 16.5% greater. The average price paid for what is known as Pennsylvania petroleum, which comprises nearly

95% of the production of the Appalachian field, was $1.2375 per barrel in 1902, that for 1901 having been $1.21—a gain of nearly 3 cents per barrel. There was also a gain of nearly 4 cents per barrel in the price of the Lima-Indiana petroleum in 1902 over 1901. California petroleum decreased 21.8 cents per barrel in 1902 as compared with 1901, and Texas petroleum decreased 4 55 cents per barrel.

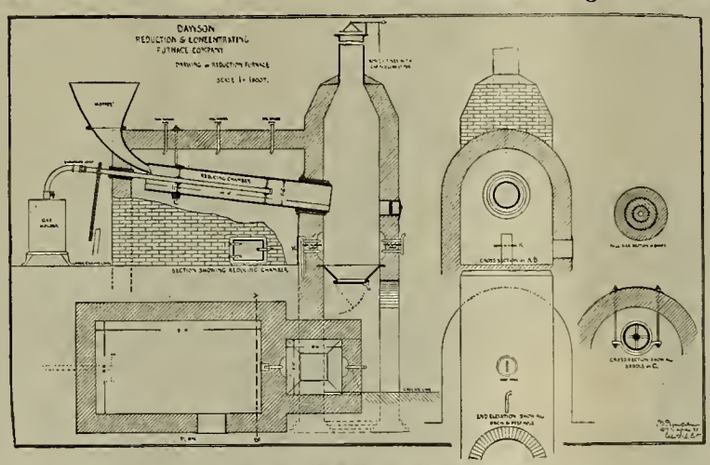
A New Reduction Process.

Written for the MINING AND SCIENTIFIC PRESS by O. B. DAWSON.

There will shortly he placed upon the market a new furnace, to he operated under an economy of lahor, time and fuel, for the purpose of reducing minerals in the gangue to a metallic, spongy condition, and hy the elevation of the temperature, concentrate the metal into approximately glohular, shot-like masses.

This differs radically from the process which involves the three operations of roasting, smelting and hessemerizing, and is designed to he accomplished by the agency of hydrogen reduction. Through slow roasting, hy present processes, sulphides are converted into oxides, from which matte is made by smelting. The further treatment of the matte hy hessemerizing is essential to reduce it to a metallic state. This operation is intended to hring ahout a complete reduction of the metal under a temperature slightly above the heginning of incandescence. Patents are issued covering this process and the furnace, hoth in America and foreign countries.

The intent is to exclude the air and introduce a practically pure hydrogen gas for taking off all oxygen not so required, so as to prevent the formation of metallic salts, such as oxides, carhonates, chlorides, sulphides, etc., and hydrogenize the elements naturally combined with and extracted from the metals. The ore in its natural state and without any flux is passed through a reducing chamher where it is suhjected to a degree of heat ahout equal to that of the beginning of incandescence, that is, about 1000° F., the heat heing applied externally. While the ore is thus heing heated in the reducing chamher in the presence of the products of comhustion arising from the externally applied heat, which products intermingle with the ore, suhstantially pure hydrogen gas is introduced for the purpose of comhining with the sulphur the oxygen and other metalloids present in the minerals. The amount of hydrogen must he slightly in excess of the amount necessary to comhine with these metalloids, so that if oxygen should enter with the products of comhustion it will combine with the hydrogen gas, preventing the formation of oxides. The hydrogen has a stronger affinity for oxygen than has the metals, and it will also take from carhon dioxide part of its oxygen, thereby forming a reducing gas and at the same time prevent the formation of metallic carhonates, etc. The gases thus heing driven off hy combining with the hydrogen, the gangue hecomes cellular, permitting the hydrogen gases to readily and effectively commingle with the minerals and therehy reduce them to a metallic, spongy condition. Because of the excess in the supply of hydrogen gas, there is always sufficient present to maintain the metals in this metallic condition.



While still heated and in the condition mentioned the metals pass into a practically air-tight concentrating chamher still in the presence of hydrogen, where they are suhjected to a higher degree of heat than that required in the reducing chamher. The metals, heing thus fused, collect in approximately glohular masses within the gangue, after the form of shot or nuggets, and may suhsequently be readily removed from the fragile gangue hy crushing.

Of course, owing to the necessity of the presence of oxygen for the promotion of the comhustion necessary to effect the heating of the ores in the reducing chamher, a certain amount of CO and CO^2 will have a tendency to intermingle with the ores, but hy reason of the excessive supply of hydrogen gas no oxides can be produced. All of the mineral is reduced to a metallic state, the hydrogen gas combining with all the sulphur, oxygen and other gases or metalloids given off hy the minerals. It will he understood, therefore, that oxides and carbonates will not he formed. The amount of hydrogen gas present being in excess of that required for combining with and carrying off the gases mentioned, enters into the cellular gangue and thereby freely acts upon the minerals, reducing them and keeping them in a metallic, spongy condition. The gangue is thus made cellular hy reason of the withdrawal and consumption of the gases naturally and previously comhined with the minerals.

In the Bullion mountains, San Bernardino county, Cal., the process will shortly be given a thorough and complete field test, which is expected to demonstrate the practicahility of this furnace under usual conditions of mining reduction, and the treating of sulphides and carhonate ores. This plant, which was erected by Lewellyn Bros. and the Lacy Mfg. Co. of Los Angeles, Cal., is approximately a 50-ton plant, and will he in operation in Septemher. It is near the center of the Lava Bed mining district.

An experimental plant of approximately five tons a day has heen in operation in New York City for ahout eight months in reduction works first estahlished at Caldwell, N. J., and has heen re-erected in New York City on a somewhat larger scale, where ores are being successfully treated from several mining sections of this country. Sulphides, carhonates and chlorides have heen most generally treated.

The inception of this process came ahout hy the request of a prominent manufacturer of gold foil to produce a spongy condition of pure gold, of such form and consistency that it would he malleahle and weld easily hy reason of its absolute purity. This was first undertaken a number of years ago, and after the process was formulated, a furnace was devised to carry it out on a commercial scale. The reduction and concentrating furnace herein described is the outcome of years of experimental work.

The Dawson Reduction Furnace.

By experiment, silver chloride has heen found to he the easiest of all minerals reducihle to a metallic state. Next, perhaps, comes iron oxide, and following this are the carhonates and oxides of copper. The sulphides of copper require a somewhat longer time and slightly higher temperature.

The secret of the process is the practical exclusion of air, the maintenance of an approximate temperature of 1000°, and the presence of an excessive amount of hydrogen throughout the entire act of reduction and concentration. The hydrogen prevents the formation of metallic salts and permits the metal to remain in a metallic state after its reduction. After the reduction the metal passes into a supplementary chamher still under the action of hydrogen, the temperature is increased several hundred degrees, the metal melts and collects into glohular masses within the coke-like gangue. At no time is liquid slag formed. The gangue is then automatically dumped from the receptacle at the hase of the secondary furnace and when cold passed hetween rollers. This resultant is a very fragile, coke-like matter containing the little particles of metal. This can he readily separated hy any of the standard mechanical separators in general use. It is helieved that the process is one which saves time and lahor cost, and one that can he operated at a great reduction in fuel expense, and that by its use much lower grade ores can he successfully worked. Some of the tailings now considered of little value can pass through the reduction chamher of this furnace at a considerable margin of profit.

As will he noticed by reference to the engraving herewith, the furnace is hopper-fed, and can he dumped at intervals without in any way interrupting the feed or the continuous process of reduction.

If desirahle several reduction chambers can he installed within the same comhustion chamher. This will in no way change the process or render it less effective, resulting only in an increase of capacity.

In cost the installation of the process is comparatively slight. The installation of a 50-ton plant would cost approximately $10,000, and larger plants could he installed at a cost smaller proportionately.

One of the strongest features, from the miner's standpoint, is that all that is essential to the successful operation of this furnace in the way of fuel is charcoal, which can readily he produced at almost any camp, or crude oil, if the latter is more easily obtainahle. No matter how inaccessible the mining plant may be to coal delivery, the question of transportation or inaccessihility of freight will thus he largely eliminated. By the use of wood the gas may be produced, hoth for fuel and reduction purposes, at a cost which makes it attractive to the furnace operator. Of course, if coal or coke are readily ohtainahle at a reasonahle cost, they may he used with equal facility.

Gold Mines of San Diego County, Cal.*

Any one who has not traversed the west half of America finds it difficult to form a just idea of its vastness of extent and variety of mineral wealth. Any one of the mining States of the American Union, of the Provinces of British America, or of the States of the Mexican Repuhlic, has tremendous area of mineral ground that justifies most extended notice. Nearly every part of this great region has received illustrated notice herein through the 43 years of this journal's existence, but necessarily in a desultory way. Last week's issue contained notices of some "Southern California" mines, viz., on the desert, in Kern county. On the front page of this issue appear some illustrations of typical gold mines still farther south, yet in California; for, like several of its sister States, California is a commonwealth of enormous extent. For instance, the California gold mines illustrated in this week's issue are in one county—San Diego—(there are 57 counties in California) and, though in the same county, these mines are some of them nearly 200 miles apart.

To Mr. R. S. Baverstock of Los Angeles, Cal., we are indehted for the photos and notes concerning the mines in the extreme eastern part of San Diego county, and close to the Colorado river. Figs. 1, 2 and 3 represent these mines. Fig. 1 shows what comprised till recently the largest number of stamps under one roof in California, it heing a view of the 100-stamp mill looking north, with the hoist and track on the left of the Queen mine. Just hack of the writer is the famous "Glory Hole," from which hundreds of thousands of tons of low-grade ore have been milled.

Fig. 2 represents a view looking south, and showing in the distance the 100-stamp mill of the Golden Cross, and on the left of it the hig mass of tailings which are heing worked by cyanide. This bank fills up a valley about half a mile in width, and in many places 30 to 40 feet deep. On the right of the picture is the precipitation plant, and in the foreground are seen the cars filled with tailings, waiting to he hauled up the incline and discharged into the 500-ton vats, of which there are five. The old 40-stamp mill does not show in the picture, hut is just on the left of it. The cyanide plant is heing successfully operated hy Manager Barker, who is making sufficient profit out of $1 tailings to put the property in good shape, and this with water pumped 14 miles. No effort is heing made at present to operate the stamp mill.

Fig. 3 represents the American Girl mine looking west, showing the mill, cyanide plant and hoist, and, heyond, the shaft house of the Randolph mine. This plant is not at present heing operated. The mine is developed to a depth of about 700 feet on the incline, and large hodies of ore have heen hlocked out; hut, owing to change of character, the owners are considering the equipment of a plant suited to the ore and installing a water supply sufficient for handling 250 tons daily. There are up to date over 2 miles of underground workings in the mine, and, heside this property, another one on the same ledge east has a large amount of ore hlocked.

Fig. 4 shows the old Stonewall mine, on the Cuyamaca grant, east of the city of San Diego ahout 60 miles. This mine was famous under the administration of Governor Waterman of California. The shaft is ahout 600 feet deep. The mine has a 20-stamp mill and is heing reopened hy S. W. Lucas and Boston men, who have not only acquired the mine, hut the grant, which is one of the finest cattle ranges in southern California. It consists of about 20,000 acres and embraces Cuyamaca Peak, the highest point in that section, and thousands of acres of pine, cedar, oak and other timher. The mill is heing started up on the old dump, which consists of thousands of tons of low-grade ore, which with modern milling methods will show a profit. In the meantime the work of unwatering the deep shaft has begun.

There is much activity in the Julian mines; nearly all the old properties are being reopened and put in good working order. Julian and Banner are the oldest gold camps in southern California, mines there having been in constant operation almost 35 years.

Fig. 5 shows the hoist and mill of the Helvetia mine, near Julian, which is in active operation, and now producing ore that is reported to carry high values in telluride. Fig. 6 represents the old Gold King mine and mill at Banner, where it, the Golden Chariot and others have shared the fluctuating fortunes characteristic of so many California camps.

*See illustrations front page.

Bituminous Rock in California.

Bituminous sandstone in California is usually in Tertiary form, the stratified ledges being overlaid by chalk rock, or compressed silt, which, being removed, holes from 8 to 12 feet deep are bored, and after being sprung with dynamite are blasted with black powder. The rock is made up of finely divided sand, each grain of which is surrounded by a miniature encasement of bitumen. That containing about 16% of bitumen free from oil is in greatest commercial demand, though the residual asphalt from the Kern, Cal., oil refineries is a present competitor of the mining of bitumen in California. The oil measures of California are but another form of the same thing. In the case of bituminous rock the oil passed upward from the horizon in which it was generated, impregnating the soft, loose sandstone. In places the oil issues from the shales, forming a surface accumulation; where overlain by sandstone it percolates therethrough, and in the course of ages has formed extensive masses of bituminous rock. This naturally mixed compound was in extensive use when manufactured for street paving purposes, but the residual asphalt from southern California has of late years proved an active competitor for popular favor. The engravings herewith are of two bitumen mines about 9 miles west of the Pacific ocean, 3 miles from the city of Santa Cruz, Cal., at an altitude of 800 feet.

Santa Cruz, Cal., Bitumen Mine No. 1; Medium Rock.

The term "bituminous rock" is usually applied to a stratified sandstone thoroughly impregnated, as is the rock depicted herewith by heavy oil. When fresh it is a black plastic tough mass; when dried it assumes a brownish color and disintegrates. The term asphaltum is ordinarily applied to the solid or vi cous residue left upon the evaporation of the volatile constituents of a heavy oil. The group of rocks in the California Coast range, wherein these oil shales are mostly found, is characterized by considerable thickness of siliceous or flinty shales, with some of calcareous origin, which in their unaltered condition in many places appear to be made up of the remains of microscopic sea animals. The oil distilled from these shales is of different density; in some places the conditions have favored its preservation as a light volatile oil with no solid base; in others, as in the vicinity of Santa Cruz, the product remaining as a thick dark oil with a large percentage of asphaltum. Chemical action is going on in some portions of these deeply buried shales all along the California Coast range, as is evidenced by the cold and warm sulphur springs so numerous, and the fact that oil is often associated with such formation leads to the conclusion that it is still being generated, and that the gas and flowing water forces it upward. In many places the process of impregnation of bituminous rock is still going on. Great quarries of this deposit have been worked in several sections for the last twenty years.

Santa Cruz, Cal., Bitumen Mine No. 2; Soft Rock.

Notes on the Metallurgy of Copper of Montana.*

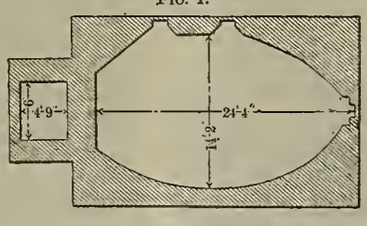
* See Fig. 2.
† The hearth has the form of a rectangle.
‡ Not comparable in this manner on account of gas producers.
⁂ The first figure represents the regular crew, the second the auxiliary labor.

The characteristics of the Montana reverheratory matting furnaces are the form of hearth and the greatness of its area. While as late as 1891 the hearth had the usual pear-shaped form of the original Welsh furnace (Fig. 1), a radical change was inaugurated hy making the hearth ohlong, tapering very quickly toward the bridge, hut less so toward the flue (Fig. 2). The result was an enlarged hearth area served by the same grate area which, on account of the free development of the flame, could heat more effectively and smelt a larger amount of charge per unit of fuel consumption than with the old form. While at Argo, Colo., the reverheratory matting furnace of 1878 had a hearth area of 105 square feet with a ratio of hearth to grate area as 4.66 : 1, in 1894 the hearth area had been increased to 481 square feet and the ratio to grate area decreased to 15.03 : 1. At present the Montana furnaces reach in round figures a hearth area of 880 square feet, with hearths 50 feet long and 20 feet wide (in the middle section, Fig. 2); the ratio of heart to grate area differs, however, only slightly from the Argo standard of 1894. Such a furnace treats 105 tons of charge in twenty-four hours, producing 50% matte with a concentration of 3 to 4 into 1. These large furnaces have many advantages over the smaller ones besides the greater capacity. The sides are less readily corroded hy the slag (claying every twelve days versus every three days), as for a given amount of matte less surface is exposed to the slag; there is less variation in temperature on account of the greater reservoir of heat, which lengthens the life of the hrick; the layer of slag is thinner, which allows quicker heating and causes less foaming when the charge is dropped from the hoppers; and the level of the matte remains more constant.

FIG. 1.



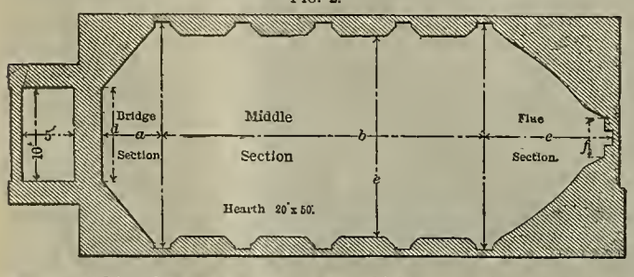


FIG. 2.

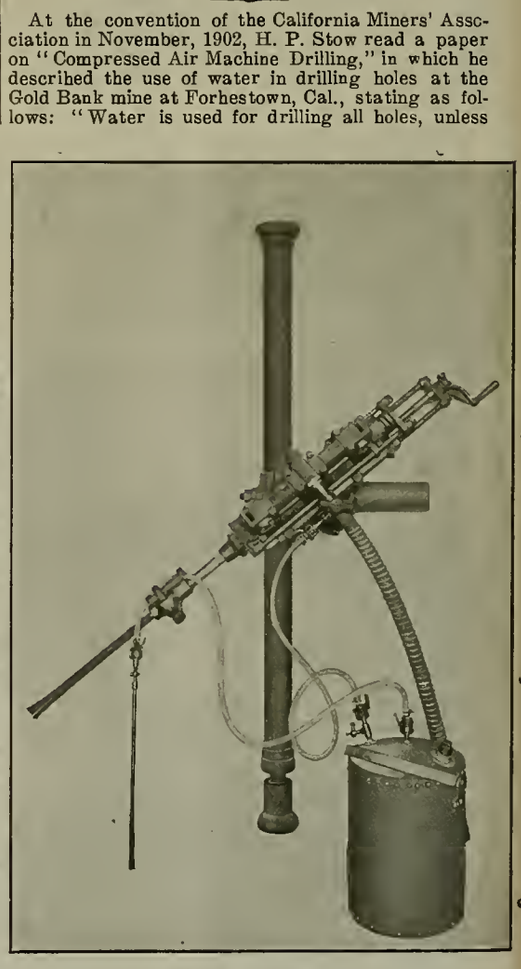
FUEL.—The fuel used is hituminous coal of various grades from Montana, Wyoming and Utah.

Most furnaces are direct fired. Some furnaces are worked with natural draft, hut the majority have under-grate hlast. In one instance the original firebox has been changed to receive a gas producer, with satisfactory results as to saving of fuel and to shortening of the time required for melting. This latter is due to the fact that the ordinary grate has to he cleaned every four hours, while the grate of the producer requires attention only once in twenty-four hours. On account of structural difficulties the producer had to he given up. In many furnaces air is admitted through the roof ahove the fire hridge in order to secure a better comhustion and thereby save fuel. The air travels through the vault underneath the furnace, rises some distance in two corners of the stack (square on the outside, circular on the inside), descends in the others, returns underneath the hearth through three or four horizontal channels on either side of the vault, rises in corresponding vertical hoxes near the hridge, enters both sides of an air chamher on the roof ahove the bridge and descends through slots into the fire-bridge flue. There is some douht prevalent as to the efficiency of this superheating. With most furnaces the heat of the flame passing out of the furnace goes to waste. The main difficulty lies in the fact that, in order to roast successfully in a reverheratory furnace, it is essential to have a steady even temperature at the fire bridge, and with a reverheratory matting furnace, charged and discharged at intervals, this is not easily obtained, if it can he managed at all. In order to utilize the waste heat, one Montana plant has attached a 300 H. P. hoiler, to one of its 50 by 20 foot furnaces. While an attempt of this kind in an Eastern refinery had proved a failure, owing to the diminished melting power caused hy the reduced force of the draught, here it proved a success, the furnace with boiler doing hetter work than the neighhoring furnace, the gases of which went directly into the main flue connected with the stack. The cause of this, at first, paradoxical result was found to lie in the fact that the furnaces were hlessed with a strong draught which drew the flames from the fireplace (worked with under-grate hlast) too quickly through the furnaces. By introducing the necessary dampers to check the draught, the work of the furnaces without appended hoilers was hrought up to that having a boiler.



One plant only has reverheratory matting furnaces with regenerative chamhers, similar to the open hearth steel furnaces with stationary hearths. Tilting furnaces (hearths 13 by 16 feet with 176 square feet area), similar to the Camphell open hearth steel furnace, which were built in 1890 and 1892, were ahandoned on account of their small capacity and hecause of the fact that it was impossihle, in pouring off the slag, to control the flow in such a manner as to prevent matte from passing over. Small amounts of matte in a large mass of slag cannot be distinguished hy the eye. These furnaces were run, however, for several years as stationary furnaces, heing gradually replaced hy furnaces of larger size. The gas producer used is 15 feet high, has a 7-foot hosh and a throat 7 feet 4 inches in diameter. The producer gasifies from 10 to 12.5 tons coal in twenty-four hours, the top making one revolution in three minutes.

(TO BE CONTINUED.)

*Trans. Am. Inst. Min. Engs. (Condensed).

Application of Water in Rock Drilling.

At the convention of the California Miners' Association in November, 1902, H. P. Stow read a paper on "Compressed Air Machine Drilling," in which he described the use of water in drilling holes at the Gold Bank mine at Forhestown, Cal., stating as follows: "Water is used for drilling all holes, unless

Portable Drilling Outfit.

possihly the very steep 'uppers,' and increases the efficiency of the drill as high as 50%. Water was used under pressure even when pumping water from the mine, tapping the pump column, and in the upper

levels, where the pressure was not sufficient, it was brought from the surface. The following test was made:

"Three rounds were drilled by the same miner, using a 2¼-inch drill, drilling the same number of hours, size, and as near as possible the holes were of the same kind. Two of the rounds were drilled without taking down the bar, and the third was put in alongside of the other two. He drilled one round without water, one with water, bailing from a bucket, the usual method; and the third with water under pressure in a hose. Without water he drilled 32 feet, using thirty-eight drills; with water by bailing, 41¾ feet, using thirty-three drills; and with water from the hose, 52 feet, using thirty-seven drills—that is, a gain of 30% depth of holes, and 50% gain of feet per drill, with bailing over drilling dry; a gain of 62½% of depth of holes and 66⅔% gain of feet per drill, using the hose over drilling dry; and a gain of 24½% depth of holes, and 11% of feet per drill by using hose over bailing water from a bucket. All of which shows that there is not only a gain of ground drilled, but a saving of drill bits used by using water under pressure, instead of bailing it from a bucket or not using it at all. Besides the actual gain in drilling, the 'pressure-water' is a saving in getting rid of the gases in the pile of dirt and the dust formed in drilling, resulting materially in the better health of the men, freedom from powder headache and miners' consumption, and increased rapidity of getting into the face to remove the dirt."

The accompanying illustration shows a portable outfit arranged by the Rix Compressed Air and Drill Co., San Francisco, Cal. It consists of a galvanized pot with a hail, holding eight gallons of water, and which, the manufacturer says, has been tested to 150 pounds per square inch pressure. This pot has openings for admitting air pressure on the water, for attaching the water hose, for filling and for releasing the air when filling is required. There are two small pieces of hose, one for admitting the air and one for the squirter. The air hose is attached to the side of the drill cock and lightning couplings are used.

The superintendent of the North Star mine at Grass Valley, Cal., writes the manufacturers: "For clear water, we put up small barrels on each level, or in the most convenient place where there is a drip, and run the clear water into this barrel, which is also protected from dust or dirt. A faucet is placed at the bottom. A boy with a heavy galvanized watering pot, fitted with a small nozzle, distributes the water to the tanks. A tank of water lasts for some time. It depends on how steadily the machine is running and how careful the man is about shutting off the water when not using it. It will last at least an hour or two anyway, and one boy can keep forty tanks supplied under reasonable conditions of water supply." If these appliances save an appreciable percentage of the cost of drilling, and save blacksmith labor, any reasonable time and care devoted to keeping up the water supply and making connections would be economical.

How to Make Blue Prints, Etc.

The simplest of all the photo-printing processes is the cyanotype, or blueprint, the paper for which may be prepared as follows: In a dark-colored or opaque bottle dissolve two ounces of citrate of iron and ammonia in eight ounces of water, and in a similar bottle dissolve one and one-quarter ounces of ferricyanide of potash in eight ounces of water. Immediately before use, mix equal portions of these solutions, and, by means of a soft sponge, a wad of cotton, or a camel's-hair brush, spread the mixed solutions evenly over the entire surface of a heavily sized white paper. Thus must be done in a room lighted with gas or other artificial light whose color tends toward yellow, and the paper should be dried quickly in a dark room or closet. The tracing is laid on a sheet of heavy glass, or, preferably, in a printing frame, with the drawing next the glass; the prepared paper is then laid over the tracing with its prepared side against the tracing cloth. A piece of heavy blotting paper, or felt, is then laid on the back of the paper, to distribute the pressure and keep the tracing and printing paper in close contact; a board is then placed over the felt, and the whole is submitted, glass side up, to the rays of the direct sunlight. In from three to ten minutes the print is removed and washed in clear water, when the entire surface becomes a deep blue color, except at the points protected by the lines of the tracing, where the paper will remain white.

After washing, the print is hung up and allowed to dry, when it is ready for use as a working drawing. Any desired alterations in the print may be made with an ordinary writing pen and a solution of caustic soda. This solution, applied to the blue portions of the print, will immediately bleach it white, while any existing lines may be obliterated by means of a little Prussian blue water color, or even an ordinary blue pencil.
